rhombic prisms. It has a styptic taste, and an acid reaction. As prepared by Bonsdorff's method, it is blue verging to green. When it becomes more green than blue, or entirely green, an indication is afforded that it contains some sesquioxide. By exposure to the air the crystals absorb oxygen, and become first green, and ultimately covered with a yellow efflorescence of subsulphate of the sesquioxide, insoluble in water. Sometimes the crystals are quite permanent when made by Bonsdorff's method, owing to the slight excess of acid which they contain. Sulphate of iron is soluble in about twice its weight of cold water, and in three-fourths of its weight of boiling water, but is insoluble in alcohol. The aqueous solution is bluish-green; but by standing it attracts oxygen, and is rendered first green and then reddish, depositing, in the mean time, a portion of sesquisulphate of the sesquioxide, having the composition $2Fe_2O_3,3SO_3+8HO$. (Wittstein, *Chem. Gaz.*, May 15, 1849, from *Buchner's Repert.*) When heated moderately, it parts with six-sevenths of its water of crystallization, and becomes grayish-white. (See *Ferri Sulphas Exsiccatum.*) At a red heat it loses its acid, and is converted into the anhydrous sesquioxide of iron, called *colcothar*. It is incompatible with the alkalies and their carbonates, soaps, lime-water, the chlorides of calcium and barium, the borate and phosphate of soda, nitrate of silver, and the acetate and subacetate of lead. It is decomposed also by astringent vegetable infusions, the tannic and gallic acids of which form, if any sesquioxide be present, a black compound of the nature of ink. To what extent this change lessens the medicinal activity of the salt, is not well ascertained. Sulphate of iron, as kept in the shops, is often the impure commercial sulphate, which is not fit for medicinal use. (See *Ferri Sulphas Venalis*, page 348.) The perfectly pure salt is precipitated white by ferrocyanuret of potassium; but that of ordinary purity gives a greenish precipitate, more or less deep, with this test, owing to the presence of some sesquioxide of iron. Copper may be detected by immersing in the solution a bright piece of iron, on which a cupreous film will be deposited. Both copper and zinc may be discovered by sesquioxidizing the iron by boiling the solution of the salt with nitric acid, and then precipitating the iron by an excess of ammonia. If the filtered solution be blue, copper is present; and if it contain zinc, this will be separated in flakes of white oxide, on expelling the excess of ammonia by ebullition. Sulphate of iron, when crystallized, consists of one eq. of acid 40, one of protoxide 36, and seven of water 63=139, and its formula is FeO,SO_3+7HO.

Medical Properties and Uses. Sulphate of iron is astringent and tonic. In large doses it is apt to produce nausea and vomiting, and griping of the bowels; and its use, when long continued, injures the stomach. It has been recommended as a remedy for the scrofulous diathesis, conjoined with extract of bark. As an astringent it is given in diseases attended with immoderate discharges, such as passive hemorrhages, colliquative sweats, diabetes, chronic mucous catarrh, leucorrhœa, gleet, &c. As a tonic it is used in dyspepsia, and in the debility following protracted diseases. In amenorrhœa with deficient action, it is frequently resorted to with advantage, either alone, or conjoined with the fetid and stimulant gums. Externally, the solution is used in eruptions of the face, chronic ophthalmia, leucorrhœa, and gleet, made of various strengths, from one or two, to eight or ten grains of the salt to the fluidounce of water. The dose is from one to five grains in the form of pill, preferably made from the dried sulphate. (See *Ferri Sulphas Exsiccatum.*) If given in solution, the water should be previously boiled to expel the air, which, if allowed to remain, would partially decompose the salt. Taken in an overdose it acts as a poison.

FERRI SULPHAS EXSICCATUM. *Ed.* FERRI SULPHAS SICCATUM. *Dub.* *Dried Sulphate of Iron.*

"Expose *any convenient quantity* of Sulphate of Iron to a moderate heat in a porcelain or earthenware vessel, not glazed with lead, till it is converted into a dry grayish-white mass, which is to be reduced to powder." *Ed.*

"Take of Granulated Sulphate of Iron *any convenient quantity*. Expose the salt in a porcelain capsule to an oven heat not exceeding 400°, until aqueous vapours cease to be given off, and, having then reduced it to a fine powder, preserve it in a well stopped bottle." *Dub.*

In these processes six eqs. out of seven of the water of crystallization of the salt are driven off. The heat should not exceed 400°, otherwise the salt itself would suffer decomposition. Dried sulphate of iron is used for making pills, the crystallized sulphate not being well adapted for that purpose. In prescribing the dried sulphate it is necessary to recollect that three grains are equivalent to five of the crystallized salt.

Off. Prep. Pilulæ Ferri Sulphatis; Pil. Rhei et Ferri. B.

FERRI SULPHAS GRANULATUM. *Dub.* *Granulated Sulphate of Iron.*

"Take of Iron Wire, or turnings of wrought Iron, *four ounces* [avoirdupois]; Oil of Vitriol of Commerce *four fluidounces* [Imp. meas.]; Distilled Water *one pint and a half* [Imp. meas.]; Rectified Spirit *ten fluidounces* [Imp. meas.]. Pour the Water on the Iron placed in a porcelain capsule, add the Oil of Vitriol, and, when the disengagement of gas has nearly ceased, boil for ten minutes. Filter now through paper into a vessel containing eight [fluid]ounces of the Spirit, and stir the mixture as it cools, in order that the salt may be obtained in minute granular crystals. Let these, deprived by decantation and draining of the adhering liquid, be washed on a funnel or small percolator with the remainder of the Spirit; and, when rendered quite dry by repeated pressure between folds of filtering paper, and subsequent exposure for twenty-four hours beneath a glass bell over a common dinner-plate half filled with oil of vitriol, let them be preserved in a well-stopped bottle." *Dub.*

The directions given in the first part of this new process are precisely the same as those laid down by the Dublin College for making sulphate of iron; but the hot solution of the iron in the sulphuric acid, instead of being allowed to filter into an empty vessel, is made to drop into a portion of rectified spirit, the mixture being stirred while it cools. The proportion of acid taken by the College forms an excess; and the filtrate is consequently an acid solution of sulphate of protoxide of iron, mixed with spirit. The stirring during cooling finely granulates the salt, which separates in a perfectly pure state; the spirit holding in solution any tersulphate of sesquioxide of iron which may have been formed, and the excess of acid dissolving any free sesquioxide. This process, in its main features, is the same as that of M. Berthemot. (See *eighth ed. of this work.*)

Properties, &c. Granular sulphate of iron is a crystalline granular powder of a bluish-white colour. When carefully dried and kept it undergoes no change. It appears to have been introduced into the officinal catalogue of the Dublin Pharmacopœia of 1850, as the best form of the sulphate for conversion into the officinal dried salt; and its peculiar state of aggregation would seem to fit it for that purpose.

Off. Prep. Ferri Sulphas Siccatum. B.

FERRI SULPHURETUM. *Ed., Dub. Sulphuret of Iron.*

"The best Sulphuret of Iron is made by heating an iron rod to a full white heat in a forge, and rubbing it with a roll of sulphur over a deep vessel filled with water to receive the fused globules of Sulphuret which form. An inferior sort, good enough, however, for pharmaceutic purposes, is obtained by heating one part of Sublimed Sulphur and three of Iron Filings in a crucible in a common fire till the mixture begins to glow, and then removing the crucible and covering it until the action, which at first increases considerably, shall come to an end." *Ed.*

"Take of rods of Iron, of the size employed in the manufacture of nails, *any convenient number.* Having raised them to a strong red or white heat, apply them in succession by their heated extremities to sticks of Sulphur, operating so that the melted Sulphuret, as it is formed, may drop into a stone cistern filled with water, and be thus protected from oxidation. The water being poured off, let the product be separated from the Sulphur with which it is mixed, and, when dried, let it be enclosed in a well stopped bottle." *Dub.*

Iron and sulphur form a number of sulphurets, among which the most important are the protosulphuret and sesquisulphuret, corresponding with the protoxide and sesquioxide of iron, the bisulphuret or *cubic pyrites*, and *magnetic pyrites*, which is a compound of five eqs. of protosulphuret, and one of bisulphuret. When the sulphuret is obtained by the application of solid sulphur to white-hot iron, the product corresponds in composition with magnetic pyrites; but, when procured by heating flowers of sulphur with an excess of iron filings, as is directed in the second of the Edinburgh processes, a protosulphuret is generated mixed with metallic iron. When sulphur is applied to white-hot iron, the metal appears to become hotter, burns with scintillations in the vapour of the sulphur, and forms instantly the sulphuret, which, being comparatively fusible, melts into globules, and drops into the water, which serves to extinguish them.

Properties, &c. The officinal sulphuret of iron has a yellowish colour and the metallic lustre. When obtained over water it is in the form of brownish-yellow globules, having a somewhat crystalline texture. When pure it furnishes a yellow powder, and dissolves in dilute sulphuric or muriatic acid without leaving a residue of sulphur, and with the production of hydrosulphuric acid gas (sulphuretted hydrogen), free from admixture of hydrogen. As prepared, however, by the officinal processes, it is not entirely soluble in dilute sulphuric acid, a portion of uncombined sulphur being left. The fused globules have the composition of $5FeS + FeS_2$, or, according to some, $5FeS + Fe_2S_3$. This preparation is employed exclusively as a pharmaceutical agent, for the production of hydrosulphuric acid gas. It may be made to yield this gas by the action of diluted sulphuric acid. During the reaction water is decomposed; its hydrogen combines with the sulphur to form hydrosulphuric acid, while the oxygen converts the iron into protoxide, with which the sulphuric acid unites. *Hydrosulphuric acid* is a colourless gas, having a smell like that of putrid eggs. Its sp. gr. is 1·1782. It saturates bases, with which it forms salts called *hydrosulphates, sulphohydrates*, or *hydrosulphurets*. It consists of one eq. of sulphur 16, and one of hydrogen 1=17.

Off. Prep. Ammoniæ Hydro-sulphuretum. B.

FERRI VALERIANAS. *Dub. Valerianate of Iron.*

"Take of Valerianate of Soda *five ounces and three drachms* [Dub. weight]; Sulphate of Iron *four ounces* [avoird.]; Distilled Water *one pint* [Imp. meas.]. Let the Sulphate of Iron be converted into a persulphate, as directed in the formula for *Ferri Peroxydum Hydratum*, and, by the addition of distilled water, let the solution of the persulphate be augmented to the bulk of eight [fluid]ounces [Imp. meas.]. Dissolve the Valerianate of Soda in ten [fluid]ounces of the Water, then mix the two solutions cold, and, having placed the precipitate which

forms upon a filter, and washed it with the remainder of the Water, let it be dried by placing it for some days rolled up in bibulous paper on a porous brick. This preparation should be kept in a well stopped bottle." *Dub.*

This is a new officinal of the Dublin Pharmacopœia of 1850. The first step in the process for making it is to convert the sulphate of protoxide of iron into the tersulphate of sesquioxide. Then by a double decomposition between this salt and valerianate of soda, sulphate of soda is formed in solution, and tervalerianate of sesquioxide of iron precipitates. The proper relative proportion of the reacting salts is three equivalents of valerianate of soda, and one of tersulphate of sesquioxide of iron; and the resulting salts are three eqs. of sulphate of soda, and one of tervalerianate of sesquioxide of iron.

Properties, &c. This salt is in the form of a dark tile-red, loose, amorphous powder, having a faint odour and taste of valerianic acid. It is insoluble in cold water, and decomposed by boiling water, which extracts all its acid, and leaves the sesquioxide of iron behind. It is soluble in alcohol. Citrate and tartrate of iron, impregnated with oil of valerian, have been fraudulently sold for valerianate of iron. The genuine salt may be distinguished from these substitutions by being insoluble in water and soluble in alcohol, and by the action of a little dilute muriatic acid, which sets free the valerianic acid, readily recognised by its disagreeable odour, which is quite distinct from that of the oil of valerian. In relation to the modes of distinguishing the true from the spurious valerianates, see the *Pharm. Journ. and Trans.*, viii. 577. Valerianate of iron has been given in hysterical affections, complicated with chlorosis. The dose is about a grain repeated several times a day. B.

FERRUM AMMONIATUM. *U. S.* Ferri Ammonio-chloridum. *Lond. Ammoniated Iron. Ammonio-chloride of Iron.*

"Take of Subcarbonate of Iron *three ounces;* Muriatic Acid *ten fluidounces;* Muriate of Ammonia *two pounds and a half;* Distilled Water *four pints.* Mix the Subcarbonate of Iron with the Muriatic Acid in a glass vessel, and digest for two hours; then add the Muriate of Ammonia, previously dissolved in the Distilled Water, and, having filtered the liquor, evaporate to dryness. Rub the residue to powder." *U. S.*

The process of the *London College* is essentially the same as the above, of which it is the original. The College, instead of a digestion of two hours, directs that it should continue until the sesquioxide (subcarbonate) is dissolved.

By the mutual action of muriatic acid and the sesquioxide of iron of the subcarbonate, water and sesquichloride of iron are formed; and the solution of the latter, being evaporated along with that of the muriate of ammonia, yields a mixture of the two salts. If any carbonate of iron be present in the subcarbonate, a portion of protochloride of iron must also be formed, which, however, would probably be converted into sesquichloride during the operation. The preparation was formerly made by subliming a mixture of red oxide (sesquioxide) of iron and muriate of ammonia. A portion of the muriate of ammonia was decomposed, the ammonia escaping, and the muriatic acid reacting upon the sesquioxide of iron so as to form water and sesquichloride of iron, the latter of which was sublimed with the undecomposed muriate of ammonia. By this mode of preparation the proportion between the two salts was variable. The present officinal plan has the double advantage of uniformity in the result, and greater facility in the process. There is no reason to believe that the sesquichloride of iron and muriate of ammonia are chemically combined in the preparation. According to Mr. Phillips, they are in the proportion of 15 parts of the sesquichloride to 85 of the muriate.

Properties. Ammoniated iron, thus prepared, is in crystalline grains, of a fine reddish-orange colour, and a sharp styptic saline taste. It is entirely soluble

in water and diluted alcohol, is deliquescent, and should be kept in well stopped bottles. By the alkalies and their carbonates, and by lime-water, it is decomposed, with the precipitation of about seven per cent. of sesquioxide of iron; and potassa in excess occasions the evolution of ammonia. Like the other chalybeates, it is incompatible with vegetable astringents. As procured by sublimation, it is of a yellow colour, and feeble odour, and is probably the result of a chemical reaction between the ingredients.

Medical Properties and Uses. This preparation unites aperient properties with those belonging to the chalybeates generally, and is said to have been used with advantage in amenorrhœa, epilepsy, scrofula, rickets, &c.; but it is at best uncertain, and is now very seldom prescribed. The sublimed preparation was formerly employed under the names of *flores martiales* and *ens martis*. From four to twelve grains may be given in the form of pill, electuary, or solution, several times a day.

Off. Prep. Tinctura Ferri Ammonio-chloridi. W.

TINCTURA FERRI AMMONIO-CHLORIDI. *Lond.* *Tincture of Ammonio-chloride of Iron.*

"Take of Ammonio-chloride of Iron [Ammoniated Iron] *four ounces;* Proof Spirit, Distilled Water, each, *a pint* [Imperial measure]. Dissolve and filter." *Lond.*

This is simply a solution of the preceding preparation in diluted alcohol. It has no special claims to attention.* W.

VINUM FERRI. *Lond.* *Wine of Iron.*

"Take of Iron Wire *an ounce;* Sherry Wine *two pints* [Imp. meas.]. Digest for thirty days, and filter." *Lond.*

A preparation under the name of Vinum Ferri was officinal in the London Pharmacopœia of 1824, but dismissed in that of 1836. It was made originally by a faulty process, in which a moistened mixture of iron and cream of tartar, exposed to the air for six weeks, was acted on with abundance of weak spirit, which failed to dissolve all the iron. The preparation admitted into the London Pharmacopœia of 1851 is much more entitled to the name of Vinum Ferri than the discarded one, and is made by a better process. It may be presumed that so much of the iron as is necessary to convert the tartar of the wine into tartrate of iron and potassa is dissolved. This must be but a small proportion of the iron taken; so that the preparation is a weak solution of tartrate of iron and potassa in wine. Wine of iron is a feeble chalybeate, and, on account of the variable quality of sherry wine, of unequal strength. It is applicable to cases requiring the use of iron, and in which the stimulant effect of the wine may be useful, or, at least, is not contra-indicated. The dose is from one to two tablespoonfuls, given several times a day. A good substitute for wine of iron may be made by dissolving an ounce of tartrate of iron and potassa in twelve fluidounces of water, previously mixed with an equal measure of sherry wine. The dose of this preparation, each fluidounce of which will contain a scruple of the double salt, is about the same as that of Vinum Ferri. B.

* As now directed by the London College, it is only half as strong as the preparation of the former Pharmacopœia, in which a pint of proof spirit was employed as the menstruum with the same amount of the chalybeate. As formerly prepared it was liable to the formation of a deposit, to prevent which the College ordered equal measures of proof spirit and water, without intending to alter the strength. It was, therefore, by inadvertence that each of the liquids was directed, in the existing formula, in the quantity of a pint, instead of half a pint. Such at least is the statement made by authority in the *London Pharm. Journ. and Trans.* (xi. 67,) Aug. 1851; and the statement is confirmed in the last edition of Philip's translation of the London Pharmacopœia (p. 290.)

GLYCERINA.

Glycerin.

GLYCERINA. *U. S., Dub. Glycerin. Sweet Principle of Oils.*

"Take of Lead Plaster, recently prepared and yet fluid, Boiling Water, each, *a gallon*. Mix them, stir briskly for fifteen minutes, then allow them to cool, and pour off the supernatant liquid. Evaporate this until it has the specific gravity 1·15, and pass a current of sulphohydric acid slowly through it until a black precipitate is no longer produced. Filter, and boil until the sulphohydric acid is driven off. Lastly, evaporate the liquid until it ceases to lose weight." *U. S.*

The Dub. College places glycerin in the Materia Medica catalogue, with this explanation:—"A sweet principle produced during saponification, sp.gr. 1·260."

In the process for making lead plaster, litharge, olive oil, and water are boiled together, with the result of decomposing the oil, the oily acids of which unite with the oxide of lead to form the plaster. At the same time the sweet principle of the oil, called glycerin, which was previously united to the oily acids to constitute the oil, is set free, becomes hydrated, and dissolves in the water. (See *Emplastrum Plumbi.*) It follows, therefore, that the plaster, while still hot and in the liquid state, contains an aqueous solution of glycerin, diffused through it. It is the plaster in this state that is made use of for preparing the latter substance in the U. S. formula. Accordingly, when the liquid plaster is mixed with an equal measure of boiling water, and the mixture stirred briskly, a solution of glycerin is obtained; which, after having been decanted, and evaporated to a limited extent, is freed from lead by sulphuretted hydrogen. The liquid is then filtered to separate sulphuret of lead, boiled to free it from sulphuretted hydrogen, and finally evaporated to expel the water, which is known to be all removed when it ceases to lose weight.

Glycerin was discovered by Scheele, by whom it was called the sweet principle of oils. It is produced, not only during the saponification of the fats and oils by oxide of lead in forming lead plaster, but also during the same process, when effected by potassa and soda in the manufacture of soap; the alkalies uniting with the oily acids, and setting the glycerin free. Hence soap-makers' waste forms the most abundant source of glycerin; but the substance from this source is apt to have more or less odour, which even percolation through animal charcoal does not always remove. A method of purifying glycerin from soap-makers' waste is given by M. Bruère-Perrin. (See *Am. Journ. of Pharm.*, xx. 549.)*

* Dr. Campbell Morfit has devised the following process for making pure glycerin on the large scale. Melt *one hundred pounds* of tallow, lard, or pressed lard in a clean iron-bound barrel by the direct application of a current of steam, and add to the melted liquid *fifteen pounds* of lime, previously slaked and made into a milk with *two and a half gallons* of water. Then cover the vessel, and continue the steaming for several hours, or until the completion of the saponification. This is known to be completed, when a portion of the cooled soap gives a smooth shining surface on being scraped with the nail, and breaks with a cracking noise. By this treatment the fat is decomposed, the oily acids unite with the lime to form an insoluble lime soap, and the liberated glycerin remains in solution in the water, along with the excess of lime. After the liquid has been sufficiently boiled, it is allowed to cool and settle, and then strained through a crash cloth. The strained liquid, containing only the glycerin and excess of lime, is carefully concentrated by steam heat, treated with a current of carbonic acid to remove the lime as carbonate of lime, boiled again to decompose any bicarbonate of lime that may have been formed, and allowed to repose. The supernatant clear liquid is finally decanted or strained off from the precipitated carbonate of lime, and concentrated, if necessary, to drive off any excess of water. The residue of the process, the lime soap, is sold to the stearic candle makers, or reconverted into saleable fat. Dr. Morfit has found his process for glycerin to combine the advantages of saving time, labour, and money. (*Silliman's Journal*, 2nd ser., xv. 429.—*Note to the tenth edition.*)

Properties, &c. Glycerin is a colourless or straw-coloured syrupy liquid, without smell when pure, unctuous to the touch, and having a very sweet taste. Its sp. gr. is 1·25, U. S., 1·26 *Dub.* It is soluble in all proportions in water and alcohol, but insoluble in ether. Notwithstanding its syrupy consistence it acts much in the same way as water, as a solvent of salts. It is not susceptible of becoming rancid, or of fermenting spontaneously. When exposed to a full red heat, it takes fire, and continues to burn with a blue flame. It does not evaporate on exposure to the air, and cannot be distilled without decomposition. It unites with sulphuric acid forming the *sulphoglyceric acid*, which is capable of combining with bases, giving rise to soluble salts called *sulphoglycerates*, having considerable analogy to the sulphovinates. By a mixture of sulphuric and nitric acids it is converted into an explosive and extremely poisonous liquid, called *pyroglycerin.* (Sobrero, *Journ. de Pharm.*, April, 1850.) M. Berthelot, of Paris, has recently (1853) succeeded in combining glycerin with a number of acids, both organic and mineral, forming neutral compounds. Among other acids, he has combined it with the fatty acids, producing, by synthesis, the organic fatty substances stearin, margarin, olein, &c. (*Chem. Gaz.*, No. 15, 1853, from the *Comptes Rendus.*) When diluted with water it affords no precipitate with hydrosulphate of ammonia or ferrocyanuret of potassium, showing the absence of lead and iron. It consists of one eq. of the hypothetical radical glyceryle (C_6H_7), united with five eqs. of oxygen, and one of water. Its formula, therefore, is $C_6H_7O_5+HO$.

Medical Properties. Glycerin is considered emollient and antiseptic. It was first used as a remedy externally, for dryness and deficient cerumen in the external ear. From its antiseptic and undrying properties, Mr. Startin, surgeon, of London, was led to suppose that it might prove useful, as an external application, in eruptions attended with fetid discharges, or with preternatural dryness or harshness of the skin. The results of his trials answered his expectations. In several diseases of the skin, such as pityriasis, lepra, psoriasis, lichen in its dry stage, and prurigo, he used it with benefit. He also found it a useful addition to lotions in the incrusted form of lupus or herpes exedens, and in various syphilitic and strumous eruptions. In the cases in which it was tried, it acted as a soothing application. It may be added to poultices and lotions in a proportion varying from one-fourth to one-sixteenth. Its effect on poultices is to keep them soft for a long time. Since the publication of the last edition of this work, glycerin has been used by a number of physicians, in a great variety of affections of the skin, as a softening and soothing application, and generally with satisfactory results. In certain cases of deafness, in which the auditory canal is dry, or obstructed by hardened wax, Dr. David Steel, of Petersburg, Va., has found glycerin useful, inserted into the canal by means of a piece of cotton, saturated with it. (*Stethoscope*, Feb. 1853, p. 101.) From its extensive solvent powers, and its intermediate qualities between those of water and oil, glycerin forms, according to M. Cap, of Paris, an excellent excipient for many medicines. It may be prepared as an ointment, for which formulæ are given by Mr. J. Laidley, and by Mr. J. H. Ecky. (See *Am. Journ. of Pharm.* xii., 118, and xxv. 27.)*

Pills and extracts, incorporated with a small proportion of glycerin, are preserved soft and free from mouldiness. B.

* Mr. Ecky's *glycerin ointment* is made as follows: Take of spermaceti *half an ounce;* white wax *a drachm;* oil of almonds *two fluidounces;* glycerin *a fluidounce.* Melt the spermaceti and wax with the oil of almonds by a moderate heat. Then, having poured the melted liquid into a wedgwood mortar, add the glycerin, and rub until the ingredients are thoroughly mixed and cold. This ointment may be used with advantage in chaps and excoriations.

GUMMI-RESINÆ et RESINOSA.

Gum-resins and Resinous Substances.

Gum-resins are concrete natural juices of plants, obtained by spontaneous exudation or incision, and consisting of gum and resin, associated for the most part with more or less essential oil, and frequently with other substances, such as extractive, bassorin, starch, wax, and various salts. The gum and resin are essential ingredients, but exist in very different proportions in the different varieties. All the gum-resins are partially soluble in alcohol and in water, but completely so in neither of these liquids. Diluted alcohol, on the contrary, dissolves them almost entirely, especially if assisted by heat. With water they form an opaque emulsion; the resin, essential oil, and other insoluble constituents being held in suspension by the dissolved gum. They are to a certain extent soluble in vinegar. Upon several of them, especially myrrh and ammoniac, carbonate of potassa so reacts as to render them soluble in water, or capable of being permanently retained in suspension by that liquid. A good method of effecting their suspension in any watery vehicle, is to rub them with a few drops of pure almond oil so as to form a smooth paste, and then very gradually add the liquid, continuing the trituration.

They are often so impure from admixture of vegetable and mineral substances, as to be unfit for use until purified. Various modes of effecting this object have been practised. Some of the gum-resins, as galbanum, are so far fusible, that they may be rendered sufficiently liquid by heat to admit of straining through a hempen cloth. Care should be taken in this process not to apply too great a heat, and it is best that the liquefaction should be effected by means of a water-bath. But several of them, as assafetida and ammoniac, are not sufficiently fusible at the temperature of boiling water to admit of being strained with facility. As they are usually brittle and pulverizable when very cold, they may be freed from the coarser impurities by powdering them in the winter season, and sifting the powder, which afterwards agglutinates with warmth. This plan is recommended by Mr. Brande in relation to assafetida, ammoniac, and galbanum. When boiled with hot water any of the gum-resins, though not dissolved, will form a semi-liquid mass capable of being strained; and this is the mode now adopted by the London College for their purification. It is liable to the objection that a portion of the volatile oil, upon which their medical virtues in part depend, is driven off; and the gum-resins thus prepared are adapted more especially for external use. The French pharmaceutists purify these substances by dissolving them in diluted alcohol, filtering, and evaporating the solution. This process, though liable in a still greater degree than that of the London College to the objection of diminishing the virtues of the medicine by driving off the essential oil, has the advantage of completely separating all insoluble substances, however minutely divided, such as fine sand or other earth, which might pass through the pores of a hempen strainer. For internal use, it is best to select the gum-resin of such quality as not to require purification. W.

AMMONIACUM PRÆPARATUM. *Lond. Prepared Ammoniac.*

"Take of lump Ammoniac *a pound;* Water *sufficient to cover the Ammoniac.* Heat the Ammoniac with the Water till they are mixed. Strain the mixture through a hair sieve, and evaporate by means of a water bath, stirring constantly, so that upon cooling it may become hard." *Lond.*

"Take of Storax, Alcohol, each, *a sufficient quantity.* Dissolve the Storax in the Alcohol, and strain the solution; then distil off the Alcohol with a gentle heat, until the Storax acquires the proper consistence." *U. S.*

"Take of Storax *a pound;* Rectified Spirit *four pints* [Imperial measure]. Dissolve and strain through linen; then with a gentle heat distil the greater part of the spirit: evaporate what remains by means of a water-bath to the proper consistence." *Lond.*

"Take *any convenient quantity* of Storax, in fine powder. Exhaust it by boiling it in successive quantities of Rectified Spirit; filter the spirituous solutions; distil off the greater part of the Spirit; evaporate the remainder over the vapour-bath to the consistence of a thin extract." *Ed.*

Storax, as found in the shops, is usually so much adulterated as to render its purification necessary, before it can be applied to the purposes for which it is officinally directed. As it is wholly soluble in alcohol, and little of its active matter is driven off at the boiling point of that fluid, there can be no chemical objection to the above process. Another method, sometimes followed, is to express, between heated iron plates, the balsam from the foreign matters with which it is associated; but, if the process be not very carefully conducted, the heat employed to melt the storax will be sufficient to dissipate a portion of the benzoic acid, which is one of its essential ingredients.

HYDRARGYRUM.

Preparations of Mercury.

HYDRARGYRUM PURUM. *Dub. Pure Mercury.*

"Take of Quicksilver of Commerce *three pounds* [avoirdupois]; Pure Muriatic Acid *half a fluidounce* [Imp. meas.]; Distilled Water *two ounces* [avoird.]. Having introduced the Quicksilver into a small glass retort, over the body of which a hood of sheet iron is supported, let the heat of a gas lamp be applied

until two-thirds of the metal has distilled over. Boil this for a few minutes with the Acid and Water, and having, by repeated affusion of distilled water, and decantation, removed the entire of the Acid, let the metal be poured into a capsule, and dried by the application of heat." *Dub.*

The mercury of commerce is usually sufficiently pure for pharmaceutical purposes; but occasionally it contains foreign metals, such as lead, tin, zinc, and bismuth, and hence the direction for its purification. Mercury, being much more volatile than the contaminating metals, rises first in distillation, while they are left behind. But it is necessary to avoid pushing the distillation too far; for in that event, some of the foreign metals are apt to be carried over. The Dublin College, on account of this danger, directs only two-thirds of the mercury to be distilled. The distilled product is boiled for a few minutes with dilute muriatic acid, which, while it does not attack the mercury, dissolves any contaminating metals which may have passed over. The distillation is directed to be performed from a glass retort over a gas lamp; but it is more conveniently conducted from an iron retort, over a common fire, into water contained in a receiver. In small operations a wash-hand basin will answer for a receiver. For other methods of purifying mercury, see *Hydrargyrum.* Millon has ascertained the curious fact, that the presence of so small a quantity as one-thousandth or one ten-thousandth of lead or zinc in mercury raises its boiling point. As it is difficult and troublesome to purify mercury by distillation, it is better to purchase pure samples of the metal, which may be always found in the market. For the properties and tests of pure mercury, see *Hydrargyrum.*

M. Violette has made known a new method of distilling mercury, or amalgamated silver, which presents many advantages. It consists in subjecting the metal, in iron vessels, to a current of high pressure steam, which serves the double purpose of imparting the necessary heat, and carrying over the mercurial vapour by a mechanical agency. (*Philos. Mag.*, Dec. 1850, from *Comptes Rendus.*)

HYDRARGYRI CHLORIDUM CORROSIVUM. *U.S.* Hydrargyri Bichloridum. *Lond.* Sublimatus Corrosivus. *Ed.* Sublimatum Corrosivum. *Dub.* *Corrosive Chloride of Mercury. Bichloride of Mercury. Corrosive Sublimate.*

"Take of Mercury *two pounds:* Sulphuric Acid *three pounds;* Chloride of Sodium *a pound and a half.* Boil the Mercury with the Sulphuric Acid until a white dry mass is left. Rub this, when cold, with the Chloride of Sodium, in an earthenware mortar; then sublime with a gradually increasing heat." *U. S.*

The London process is the same as the above, the twenty-one and a half Imperial fluidounces of sulphuric acid, taken by the College, being equivalent to three pounds.

"Take of Mercury *four ounces;* Sulphuric Acid (commercial) *two fluidounces and three fluidrachms;* Pure Nitric Acid *half a fluidounce;* Muriate of Soda *three ounces.* Mix the Acids; add the Mercury; dissolve it with the aid of a moderate heat; and then raise the heat so as to obtain a dry salt. Triturate this thoroughly with the Muriate of Soda, and sublime in a proper apparatus." *Ed.*

"Take of Sulphate of Mercury *ten pounds;* Dried Chloride of Sodium *five pounds.* Reduce each salt to a fine powder, and, having mixed them carefully by trituration in a mortar, let the mixture be introduced into an iron pot lined with clay, and by a regulated heat, applied through the intervention of sand, let the corrosive sublimate be sublimed into an earthen head placed over the pot,

and connected to it by means of lute. The product should be preserved in an opaque bottle." *Dub.*

In order to understand the above processes, which are the same in principle, it is necessary to premise that corrosive sublimate is a bichloride of mercury, consisting of two eqs. of chlorine and one of mercury. By boiling sulphuric acid in excess with mercury to dryness, a white salt is formed, which is a bisulphate of the deutoxide of mercury. (See *Hydrargyri Sulphas.*) When this is mixed with chloride of sodium (common salt), and the mixture exposed to a subliming heat, a mutual decomposition takes place. The chlorine of the common salt combines with the mercury, and sublimes as bichloride of mercury; while the sodium, oxygen of the deutoxide of mercury, and sulphuric acid unite to form sulphate of soda, which remains behind. The quantities for mutual decomposition are two eqs. of chloride of sodium, consisting of two eqs. of chlorine and two of sodium; and one eq. of bisulphate of deutoxide of mercury, consisting of one eq. of mercury, two of oxygen, and two of sulphuric acid. The two eqs. of chlorine combine with the one eq. of mercury, to form one eq. of corrosive sublimate; and the two eqs. severally, of sodium, oxygen, and sulphuric acid form, by their union, two eqs. of dry sulphate of soda. The *Edinburgh* formula is very much changed from that given in the previous edition of the Ed. Pharmacopœia. It is characterized by the small quantity of mercury taken, and by the use of nitric acid to assist the sulphuric in oxidizing the metal. The *Dublin* formula is peculiar in ordering the bisulphate of the deutoxide of mercury ready formed, under the name of sulphate of mercury, instead of preparing it as the first step of the process, as is done in the processes of the other Pharmacopœias. (See *Hydrargyri Sulphas.*)

The names given in the several Pharmacopœias to this important chloride, unfortunately, do not correspond. It is called a chloride, as it is admitted to be, in the U. S. and London Pharmacopœias, and corrosive sublimate, irrespective of chemical nomenclature, in the Edinburgh and Dublin. We should be sorry to share the opinion of the Edinburgh College that the adoption of the modern chemical nomenclature, to express pharmaceutical substances, was a great error, on account of its liability to change. Systematic nomenclature belongs to science, and its change is the inevitable consequence of the progress of the latter. In respect to the London name of *bichloride*, we think it not sufficiently distinct from *chloride*, adopted by the same College for calomel. We prefer the U. S. designation with the epithet *corrosivum*, as serving to call attention to the deleterious nature of the compound.

Preparation on the Large Scale, &c. The first step is to form the bisulphate of the deutoxide of mercury, which is effected by heating the sulphuric acid and metal together in an iron pot, so arranged as to carry off the unwholesome fumes of sulphurous acid which are copiously generated. The dry salt obtained is then mixed with the common salt, and the mixture sublimed in an iron pot lined with clay, and covered by an inverted earthen pan. The late Dr. A. T. Thomson, of London, took out a patent for forming corrosive sublimate, on the large scale, by the direct combination, by combustion, of gaseous chlorine with heated mercury. The product is stated to be perfectly pure, and to be afforded at a lower price than the sublimate made in the usual way. In order that the combination may take place, the mercury need not be heated to its boiling point, but only to a temperature between 300° and 400°. According to Dr. Maclagan, corrosive sublimate, made by this process, is liable to the objection that a proportion of calomel is always formed, occasionally amounting to ten per cent.

It may sometimes be useful to know how to make a small quantity of corrosive sublimate on an emergency. This may be done by dissolving deutoxide of mercury (red precipitate) in muriatic acid, evaporating the solution to dryness,

dissolving the dry mass in water, and crystallizing. Here a double decomposition takes place, resulting in the formation of water and the bichloride.

Properties. Corrosive chloride of mercury, as obtained by sublimation, is in the form of colourless crystals, or of white, semi-transparent, crystalline masses, of the sp. gr. 5·2, permanent in the air, and possessing an exceedingly acrid, styptic, metallic, durable taste. It dissolves in a little less than twenty parts of cold water, and in three of boiling water. A boiling saturated solution, upon cooling, lets it fall in a confused mass of crystals. It is soluble also in two and a third parts of cold alcohol, in about its own weight of boiling alcohol, and in three parts of ether. The latter solvent is capable of removing corrosive sublimate, to a considerable extent, from its aqueous solution, when agitated with it. Sulphuric, nitric, and muriatic acids dissolve it without alteration. When heated it melts, and readily sublimes in dense, white, acrid vapours, which condense, on cool surfaces, in white shining needles. Its aqueous solution renders green the syrup of violets, and is precipitated brick-red, becoming yellow, by the fixed alkalies and alkaline earths, and white by ammonia. (See *Hydrargyrum Ammoniatum.*) The former precipitate is the hydrated deutoxide of mercury, which has the property of emitting oxygen, and of being reduced to metallic globules, when exposed to heat. This oxide is formed in the process for preparing the *aqua phagedænica*, which is obtained by mixing a drachm of corrosive sublimate with a pint of lime-water. Corrosive sublimate forms with muriate of ammonia and chloride of sodium, compounds which are more soluble than the uncombined mercurial salt. It is on this account that aqueous solutions of sal ammoniac, or of common salt dissolve much more corrosive sublimate than simple water. The combination of corrosive sublimate with muriate of ammonia was formerly called *sal alembroth*, or *salt of wisdom.* (See *Liquor Hydrargyri Bichloridi.*) According to F. Hinterberger, corrosive sublimate is capable of combining with quinia and cinchonia. (*Chem. Gaz.*, ix. 211.)

Corrosive sublimate has the property of retarding putrefaction. Animal matters, immersed in its solution, shrink, acquire firmness, assume a white colour, and become imputrescible. On account of this property it is usefully employed for preserving anatomical preparations.

Tests of Purity and Incompatibles. Pure corrosive chloride of mercury sublimes, when heated, without residue, and its powder is entirely and readily soluble in ether. Consequently, if a portion of any sample should not wholly dissolve in ether, or if it should not evaporate entirely, the presence of some impurity is proved. If calomel be present, it will not be wholly soluble in water. Corrosive sublimate is incompatible with many of the metals, with the alkalies and their carbonates, with soap, lime-water, tartar emetic, nitrate of silver, the acetates of lead, the sulphurets of potassium and sodium, and with all the hydrosulphates. It is also decomposed by many vegetable and some animal substances. According to the late Dr. A. T. Thomson, it produces precipitates in infusions or decoctions of the following vegetable substances;—chamomile, horse-radish, columbo, catechu, cinchona, rhubarb, senna, simaruba, and oak-bark. The experiments of M. Mialhe and M. Lepage have shown that corrosive sublimate is slowly converted into calomel by syrup of sarsaparilla and syrup of honey, but undergoes no alteration by contact with pure syrup. B.

Medical Properties and Uses. Corrosive sublimate is a very powerful preparation, operating quickly, and, if not properly regulated, producing very violent effects. It is less apt to salivate than most other mercurials. In minute doses, suitably repeated, it may exert its peculiar influence without any obvious alteration of the vital functions, except, perhaps, a slight increase in the frequency of the pulse, and in the secretions from the skin and kidneys. Sometimes, however, it purges; but this effect may be obviated by combining it with a little

opium. In larger doses it occasions nausea, vomiting, griping pain in the bowels, diarrhœa, and other symptoms of gastric and intestinal irritation; and in still larger quantities produces all the effects of a violent corrosive poison. It has long been used as a remedy in syphilis, in all stages of which it is highly recommended by some authors. It is said to remove the symptoms more speedily than other mercurials; while its action is less unpleasant, as the mouth is less liable to be made sore. For the latter reason it has been much employed by empirics, and is an ingredient in most of those nostrums which have at various periods gained a temporary popularity as anti-venereals. But while it is extolled by some authors, others, among whom is Mr. Pearson, of London, deny its extraordinary merits, and maintain that, though occasionally useful in arresting the progress of the complaint, particularly in the secondary stage, it does not produce permanent cures, and, in the primary stage, often fails altogether. On the whole it appears to be best adapted to secondary syphilis, in which it occasionally does much good. It is also used advantageously in some chronic cutaneous affections, and in obstinate chronic rheumatism. It is usually associated with alterative or diaphoretic medicines, such as the antimonials, and the compound decoction or syrup of sarsaparilla; and, in order to obviate the irritation it is apt to produce, it may often be advantageously united with opium, or extract of hemlock. There is no doubt that many of the substances in connexion with which it is employed, alter its chemical condition; but it does not follow that, even in its altered state, it may not be very useful as a remedy.

Externally employed, corrosive sublimate is stimulant and escharotic. A solution in water, containing from an eighth to half a grain in the fluidounce, is employed as an injection in gleet, as a gargle in venereal sore-throat, and as a collyrium in chronic venereal ophthalmia. A stronger solution, containing one or two grains in the fluidounce, is an efficacious wash in lepra, and other scaly eruptions. Dissolved in water, in the proportion of five or ten grains to the fluidounce, it may be used with much benefit in venereal ulcers of the throat, to which it should be applied by means of a camel's hair pencil. With lime-water it forms the *aqua phagedænica* of the older writers, employed as a wash for ill-conditioned ulcers. The powdered chloride has been used as an escharotic; but is, in general, inferior to nitrate of silver or caustic potassa. In *onychia maligna*, however, it is employed with great advantage, mixed with an equal weight of sulphate of zinc, and sprinkled thickly upon the surface of the ulcer, which is then to be covered with a pledget of lint saturated with tincture of myrrh. The whole diseased surface is thus removed, and the necessity of resorting to the knife avoided. This practice was first introduced, we believe, by the late Dr. Perkins, of Philadelphia, and was highly recommended by Dr. Physick. We have employed it in several instances with complete success.

The dose of corrosive sublimate is from the twelfth to the quarter of a grain, repeated three or four times a day, and given in pill, or dissolved in water or spirit. The pill, which is the preferable form, is usually prepared with crumb of bread; and care should be taken that the medicine be equally diffused through the pilular mass, before it is divided. Mucilaginous drinks are usually given to obviate the irritating effects of the medicine.

Toxicological Properties. Swallowed in poisonous doses, it produces burning heat in the throat, excruciating pain in the stomach and bowels, excessive thirst, anxiety, nausea and frequent retching with vomiting of bloody mucus, diarrhœa and sometimes bloody stools, small and frequent pulse, cold sweats, general debility, difficult respiration, cramps in the extremities, faintings, insensibility, convulsions, and death. The mucous membrane of the stomach exhibits on dissection all the signs of the operation of a violent corrosive poison. These symptoms are sometimes followed or conjoined with others indicating an excessive

mercurial action upon the system, such as inflammation of the mouth and salivary glands, profuse salivation, fetid breath, &c. A case is on record of death, in an infant, from the constitutional effects of corrosive sublimate sprinkled upon an excoriated surface. In the inferior animals, in whatever mode introduced into the system, it is said to occasion irritation of the stomach and rectum, inflammation of the lungs, oppression of the brain, and depression if not inflammation of the heart. (*Christison.*) In the treatment of poisoning by corrosive sublimate, Orfila recommends the free use of the white of eggs beat up with water. The albumen forms an insoluble and comparatively innocent compound with the corrosive sublimate; and the liquid by its bulk dilutes the poison, and distends the stomach so as to produce vomiting. It is, however, asserted by M. Lassaigne that this compound of albumen and corrosive sublimate, when recently precipitated, is soluble in acid and alkaline liquids, and in solutions of the chlorides of potassium, sodium, and calcium. (See *Journ. de Pharm.*, xxiii. 510.) It is, therefore, important, at the same time that the antidote is used, to evacuate the stomach before the newly formed compound can be dissolved. If eggs cannot be procured, wheat flour may be substituted; gluten having, according to M. Taddei, the same effect as albumen. Milk has also been recommended, in consequence of the insoluble compound which casein forms with the poison. Besides the antidotes mentioned, Peruvian bark, meconic acid, protosulphuret of iron, and iron filings have been proposed, all of which have the property of decomposing corrosive sublimate. The protosulphuret of iron was found quite successful by M. Mialhe in experiments upon dogs, if given immediately after the poison was swallowed, but failed when delayed for 10 minutes. It is of the utmost importance that whatever antidote is used should be given without delay, and in this respect the one nearest at hand may be considered the best. Should neither of the substances mentioned be attainable, mucilaginous drinks should be largely administered; and, in any event, the patient should be made to drink copiously, so long as vomiting continues, or till the symptoms are relieved. Should he be unable to vomit, the stomach should be washed out by means of the stomach pump. The consecutive inflammation should be treated with general or local bleeding, fomentations, and cooling mucilaginous drinks, and the attendant nervous symptoms should be alleviated by opiates. W.

Tests for Corrosive Sublimate. On account of the extreme virulence of this chloride as a poison, the reagents by which it may be detected form a subject of study of the utmost importance, as connected with medico-legal investigations. The best tests for determining its mercurial nature, mentioned in the order of their delicacy, are ferrocyanuret of potassium, lime-water, carbonate of potassa, iodide of potassium, ammonia, sulphuretted hydrogen, and protochloride of tin. *Ferrocyanuret of potassium* gives rise to a white precipitate (ferrocyanuret of mercury), becoming slowly yellowish, and at length pale-blue. *Lime-water* throws down a yellow precipitate of hydrated deutoxide. *Carbonate of potassa* causes a brick-red precipitate of carbonate of mercury. *Iodide of potassium* produces a very characteristic pale-scarlet precipitate of biniodide of mercury. This precipitate frequently appears at first yellow. *Ammonia* gives rise to a fine, white, flocculent precipitate, the officinal ammoniated mercury, or white precipitate. *Sulphuretted hydrogen* occasions a black precipitate of bisulphuret of mercury; and the same precipitate is thrown down by hydrosulphate of ammonia. Finally, *protochloride of tin* causes a grayish-black precipitate (mercury in a finely divided state), and, as a test, is not liable to any fallacy. Taking the results of Devergie, the relative delicacy of these tests may be expressed numerically as follows:—Ferrocyanuret of potassium 1½; lime-water 4; carbonate of potassa 7; iodide of potassium 8; ammonia 36; sulphuretted hydrogen or hydrosulphate of ammonia 60; and protochloride of tin 80. To the above the following tests

may be added, easily applied even by one unacquainted with chemistry. *A bright plate of copper*, immersed in a solution containing corrosive sublimate, is instantly tarnished, and, after the lapse of half an hour, becomes covered with a grayish-white powder. *A polished piece of gold*, moistened with the mercurial solution, and touched through the liquid with a piece of iron, contracts a white stain. This test, which was proposed by Mr. Sylvester and simplified by Dr. Paris, is conveniently applied by moistening, with the suspected solution, a gold coin or ring, and touching it through the moistened spot with the point of a penknife. The object of the iron is to form with the gold a simple galvanic circle, which enables the latter metal to precipitate the mercury on its surface. Nearly all the above tests merely show the mercurial nature of the substance acted on. To determine whether the metal is united with chlorine, the mercurial liquid may be precipitated by lime-water, and the filtered solution, acidulated with nitric acid, then tested with nitrate of silver. If the mercury is in the state of chloride, the filtered solution will be one of chloride of calcium, which, with nitrate of silver, will yield a heavy white precipitate (chloride of silver), insoluble in nitric acid, but soluble in ammonia. The nitrate of silver may be added directly to the mercurial liquid; and, if it contain corrosive sublimate, chloride of silver will fall, but probably mixed with calomel.

By the combined indications of the foregoing tests, corrosive sublimate may be infallibly detected, unless it exists in very minute quantity, associated with organic substances, by which its presence is often greatly obscured. When it exists in organic mixtures, made by boiling the contents or substance of the stomach in distilled water, Dr. Christison recommends that a preliminary trial be made with the protochloride of tin, on a small portion filtered for the purpose. If this causes a grayish-black colour, he shakes the mixture, as recommended by Orfila, with a fourth of its bulk of ether, which dissolves the corrosive sublimate and rises to the surface. The ethereal solution is then evaporated to dryness, and the dry salt obtained is dissolved in hot water, whereby a pure solution is procured, in which the poison may be readily detected by the ordinary tests. If the trial test should produce a light gray colour, the corrosive sublimate is indicated in still less quantity, and Dr. Christison recommends to proceed in the following manner. Treat the unfiltered mixture with protochloride of tin, as long as any precipitate is formed, which will have a slate-gray colour. Collect, wash, and drain it on a filter, and, having removed it without being dried, boil it, in a glass flask, with a moderately strong solution of caustic potassa, until all the lumps disappear. The alkali will dissolve all animal and vegetable matter; and, on allowing the solution to remain at rest, a heavy grayish-black powder will subside, which consists chiefly of metallic mercury, and in which small globules of the metal may sometimes be seen with the naked eye, or by the aid of a magnifier.

Off. Prep. Hydrargyri Iodidum Rubrum; Hydrargyrum Ammoniatum; Liquor Hydrargyri Bichloridi. B.

LIQUOR HYDRARGYRI BICHLORIDI. *Lond. Solution of Bichloride of Mercury.*

"Take of Bichloride of Mercury [corrosive sublimate], Hydrochlorate of Ammonia, each *ten grains;* Distilled Water *a pint* [Imperial measure]. Dissolve." *Lond.*

This solution was intended to facilitate the dispensing of corrosive sublimate in small doses. The muriate of ammonia has been substituted for the alcohol formerly added to the solution, probably in order to prevent the decomposition of the bichloride. A solution of corrosive sublimate in water alone, under the influence of light, deposits calomel, while muriatic and chloric acids remain in the water; nor is this decomposition prevented by the addition of alcohol. The

dose of the solution, of which a fluidounce contains half a grain of corrosive sublimate, is from one to four fluidrachms, taken in flaxseed tea. W.

HYDRARGYRI CHLORIDUM MITE. *U. S.* HYDRARGYRI CHLORIDUM. *Lond.* CALOMELAS. *Ed., Dub.* *Mild Chloride of Mercury. Calomel.*

"Take of Mercury *four pounds;* Sulphuric Acid *three pounds;* Chloride of Sodium *a pound and a half;* Distilled Water *a sufficient quantity.* Boil two pounds of the Mercury with the Sulphuric Acid, until a dry white mass is left. Rub this, when cold, with the remainder of the Mercury, in an earthenware mortar, until they are thoroughly mixed. Then add the Chloride of Sodium, and rub it with the other ingredients till all the globules disappear; afterwards sublime. Reduce the sublimed matter to a very fine powder, and wash it frequently with boiling Distilled Water, till the washings afford no precipitate upon the addition of Solution of Ammonia; then dry it." *U. S.*

The *London* formula is the same as the above, except that a measure of sulphuric acid is taken, equivalent to three pounds, and the testing of the washings is not directed.

"Take of Mercury *eight ounces;* Sulphuric Acid (commercial) *two fluidounces and three fluidrachms* [Imperial measure]; Pure Nitric Acid *half a fluidounce* [Imp. meas.]; Muriate of Soda *three ounces.* Mix the Acids, add four ounces of the Mercury, and dissolve it with the aid of a moderate heat. Raise the heat so as to obtain a dry salt. Triturate this with the Muriate of Soda and the rest of the Mercury till the globules entirely disappear. Heat the mixture by means of a sand-bath in a proper subliming apparatus. Reduce the sublimate to fine powder; wash the powder with boiling Distilled Water until the Water ceases to precipitate with solution of iodide of potassium, and then dry it." *Ed.*

"Take of Sulphate of Mercury *ten pounds;* Mercury of Commerce *seven pounds;* Dried Chloride of Sodium *five pounds.* Incorporate as completely as possible the Sulphate and the metallic Mercury by prolonged trituration, and, having then added the Chloride of Sodium previously reduced to a fine powder, rub all well together until a perfectly equable mixture is obtained. Heat this, through the medium of sand, in a shallow iron pot with a flat bottom, lined with clay, and covered with a lid of cast iron, until the sublimate which attaches itself to a circular plug in the centre of the lid (which admits of being removed and cleaned from time to time) neither exhibits minute globules of mercury, nor is rendered yellow by being touched with a solution of potash. The whole being now permitted to cool down to the temperature of the air, the contents of the pot are to be transferred to a small hot-hearth or oven, whose door is made tight by a clay lute, and a regulated heat is to be applied so as to cause the vaporized Calomel to pass into an adjacent chamber of considerable size, on the floor of which it will accumulate in the form of a fine white powder." *Dub.*

The object of the above processes, which all coincide in the principle on which they are conducted, is to obtain the protochloride of mercury. This chloride consists of one eq. of chlorine and one of mercury, and consequently contains precisely half as much chlorine as corrosive sublimate, combined with the same quantity of mercury. In the process of the U. S. Pharmacopœia, as in the case of corrosive sublimate, a bisulphate of the deutoxide is first formed; but, instead of being immediately sublimed with the chloride of sodium, it undergoes a preparatory trituration with the same quantity of mercury as was employed in forming it. This trituration may be conceived to take place between one eq. of the bisulphate of the deutoxide, and one of metallic mercury, which are thus converted into two eqs. of the monosulphate of the protoxide. This change will be easily understood, by adverting to the fact, that the bisulphate of the deut-

oxide consists of two eqs. of sulphuric acid, two of oxygen, and one of mercury; and, when rubbed up with one additional eq. of mercury, the whole becomes two eqs. of acid, two of oxygen, and two of mercury, evidently corresponding with two eqs. of the monosulphate of the protoxide. The two eqs. of monosulphate thus formed, being heated with two eqs. of common salt, the two eqs. of chlorine in the latter sublime in union with the two eqs. of mercury in the former, and generate two eqs. of protochloride of mercury; while the two eqs., severally, of sulphuric acid, oxygen, and sodium, unite together to form two eqs. of dry sulphate of soda, which remain as a fixed residue. It is hence apparent that the residue in this process and in that for corrosive sublimate is the same.

The calomel in mass, as sublimed, is liable to contain a little corrosive sublimate; and hence the direction of the U. S. Pharmacopœia to reduce the sublimed matter to a very fine powder, and to wash it with boiling distilled water until ammonia produces no precipitate with the washings. Ammonia occasions a white precipitate (ammoniated mercury) so long as the washings contain corrosive sublimate; and when it ceases to produce this effect, the operator may rest satisfied that the whole of the poisonous salt has been removed. The London Pharmacopœia prescribes a careful washing, but omits in the formula any directions for testing for corrosive sublimate.

The *Edinburgh* formula is peculiar in ordering a small proportion of nitric acid to assist the sulphuric acid in oxidizing the mercury, as is done also in the corrosive sublimate process. The washings are tested by iodide of potassium, which is not so delicate a test as ammonia. The *Dublin* process includes no directions for making the bisulphate of the deutoxide of mercury; because that salt, in the Dublin Pharmacopœia, is made by a separate formula, and designated by a distinct name, *sulphate of mercury*. It is, therefore, taken ready formed, mixed with the mercury and common salt in the usual way, and the mixture is submitted to a preliminary sublimation to separate metallic mercury and corrosive sublimate. The product is allowed to cool, and then transferred to a small oven, connected with a chamber of considerable size; and, heat being applied, the vaporized calomel condenses in the chamber, and falls on its floor in the powdery form. By thus using a large cool chamber, the calomel does not require to be pulverized, but is got at once in the form of powder. The Dublin College orders no washing, which is a defect; for although the preliminary sublimation separates corrosive sublimate, yet some accidental circumstance may prevent the whole of it from being removed in this step of the process, in which case the sublimed powder will be contaminated with the poisonous chloride.

Preparation on the Large Scale. The process for making calomel by means of the bisulphate of deutoxide of mercury, was originally practised at Apothecaries' Hall, London. The proportions taken and the mode of proceeding in that establishment are, according to Mr. Brande, as follows: 50 lbs. of mercury are boiled to dryness with 70 lbs. of sulphuric acid, in a cast iron vessel; and 62 lbs. of the dry salt formed are triturated with 40½ lbs of mercury till the globules disappear, and the whole is mixed with 34 lbs. of common salt. The mixture is sublimed from an earthenware retort into an earthenware receiver, and the product is from 95 to 100 lbs. of calomel in mass. This is then ground to an impalpable powder, and washed with a large quantity of distilled water.

The object of bringing calomel into a state of minute division is more perfectly accomplished by the method of Mr. Joseph Jewell, of London, improved by M. Ossian Henry. It consists in causing the calomel in vapour to come in contact with steam in a large receiver, whereby it is condensed into an impalpable powder, and perfectly washed from corrosive sublimate, in the same operation. Calomel made by this process, sometimes called Jewell's or Howard's *hydrosublimate of mercury*, is free from all suspicion of containing corrosive sublimate, is

much finer than when obtained by levigation and elutriation, and possesses more activity as a medicine. This kind of calomel is included in the French Codex under a distinct name (*mercure doux à la vapeur*). M. Soubeiran, of Paris, has perfected a process for obtaining calomel in an impalpable powder, by substituting the agency of cold air for that of steam for the purpose of condensing it; a process which he believes to be precisely the same as that pursued by the English manufacturers, and which produces a calomel equal to the best English. A description of his apparatus may be found in the *Journ. de Pharm.*, 3e *sér.*, ii. 507. For an account of the English apparatus, as described by F. C. Calvert, see *Journ. de Pharm.*, 3e *sér.*, iii. 121. Both these papers are copied into the *Am. Journ. of Pharm.*, xv. 89 and 93.

Properties. Mild chloride of mercury is a tasteless, inodorous substance, insoluble in water, alcohol, and ether, less volatile than corrosive sublimate, unalterable in the air, but blackening by long exposure to light. When in mass its form and appearance depend on the shape and temperature of the subliming vessel. In this state it is generally in the form of a white, fibrous, crystalline cake, soft and brittle, the interior surface of which is often studded with shining transparent crystals, having the shape of quadrangular prisms, and a texture somewhat horny and elastic. When the mass is scratched it yields a yellow streak, which is very characteristic. Its sp. gr. is 7·2. The officinal form of this chloride is that of powder, in which state it is always kept in the shops. The powder has a light buff or ivory colour, if obtained by the levigation of sublimed masses; but if condensed at once in the form of an impalpable powder, as is the case with Jewell's calomel, it is perfectly white. To protect it from the action of the light, it should be kept in a dark place, or in bottles painted black or covered with black paper. By the action of the alkalies or alkaline earths it immediately becomes black, in consequence of the formation of protoxide, reducible by heat to the metallic state. (See *Hydrargyri Oxidum Nigrum.*) The preparation, formerly in use and still occasionally employed, under the name of *lotio nigra* or *black wash*, as a local application to syphilitic ulcers, &c., was made by adding *a drachm* of calomel to *a pint* of lime-water. By double decomposition between the calomel and lime, the black protoxide precipitates, and chloride of calcium remains in solution. The oxide, however, is not pure, but associated with undecomposed calomel, which is used in excess. Before being applied, the wash should be well shaken.

Tests of Purity and Incompatibles. Calomel, when pure, completely sublimes on the application of heat, a property which detects all fixed impurities, such as carbonate, sulphate, and phosphate of lime, sulphate of baryta, and carbonate of lead. It also strikes a black colour, free from reddish tinge, by the action of the fixed alkalies. The buff colour indicates the absence of corrosive sublimate; but whiteness by no means shows the presence of impurity. Its freedom from the corrosive chloride may be determined by washing a portion of it in warm distilled water, and then testing the water with ammonia, which will cause a white precipitate (ammoniated mercury), in case the water has taken up any of the poisonous chloride. Soluble salts of mercury may be detected by rubbing the suspected calomel with ether on a bright surface of copper, when the metal will become amalgamated, and exhibit a white stain. When this test shows impurity, the soluble salt present is probably corrosive sublimate. Calomel, containing corrosive sublimate, acts violently on the bowels; and, when the impurity has been present in considerable amount, has been known to cause death. Besides being incompatible with the alkalies and alkaline earths, calomel is also decomposed by the alkaline carbonates, soaps, hydrosulphates, and, according to some authorities, by iron, lead, and copper. It should not be given at the same time with nitromuriatic acid, for fear of generating corrosive sublimate. One of

the authors has been informed of a case, in which death, with symptoms of violent gastro-intestinal irritation, followed their simultaneous use. Agreeably to the experiments of M. Deschamps, calomel is decomposed by bitter almonds and by hydrocyanic acid. In the former case corrosive sublimate, bicyanuret of mercury, and muriate of ammonia are formed; in the latter, corrosive sublimate and bicyanuret only. Hence this writer considers it very dangerous to associate calomel with bitter almonds or hydrocyanic acid in prescription. This conclusion has been confirmed by M. Mialhe, and M. Prenleloup; and more recently it has been shown by Dr. E. Riegel, that cherry-laurel water has the power of converting calomel into corrosive sublimate. According to M. Mialhe, calomel is in part converted into corrosive sublimate and metallic mercury by muriate of ammonia, and by the chlorides of sodium and potassium, even at the temperature of the body; and hence he believes that the conversion may take place in the primæ viæ. Popular belief coincides with M. Mialhe's views in regard to the power of common salt of increasing the activity of calomel. More recently M. Mialhe has extended his observations, and now believes that all the preparations of mercury yield a certain amount of corrosive sublimate by reacting with solutions of the chlorides of potassium, sodium, and ammonium. The deutoxide and similarly constituted compounds are most prone to undergo this change. Even metallic mercury, digested with the chlorides named, is partly converted, under the influence of air, into corrosive sublimate. Dr. Gardner denies the assertion of M. Mialhe, that calomel is converted into corrosive sublimate by chlorides of the alkalifiable metals, maintaining that it is merely rendered soluble by their solutions. B.

Medical Properties and Uses. Calomel unites to the general properties of the mercurials those of a purgative and anthelmintic. It is the most valuable of the mercurial preparations, and in extent of employment is inferior to few articles of the Materia Medica. Whether the object is to bring the system under the general influence of mercury, or to produce its alterative action upon the hepatic or other secretory function, calomel, on account both of its certainty and mildness, is preferred to all other preparations, with the single exception of the blue pill, which, though less certain, is still milder, and is sometimes preferably employed. When used with the above objects, the tendency to purge which it sometimes evinces, even in very small doses, must be restrained by combining it with opium. In sialagogue or alterative doses, it is often prescribed with other medicines, which, while they give it a direction to certain organs, have their own peculiar influence increased by its co-operation. Thus it renders squill more diuretic, nitre and the antimonials more diaphoretic, and seneka more expectorant.

As a purgative, calomel owes its chief value to its tendency to the liver, the secretory function of which it powerfully stimulates. It is usually slow and somewhat uncertain in its cathartic effect, and, though itself but slightly irritating, sometimes occasions severe griping pain with bilious vomiting, attributable to the acrid character of the bile which it causes the liver to secrete. It is peculiarly useful in the commencement of bilious fevers, in hepatitis, jaundice, bilious and painters' colic, dysentery, especially that of tropical climates, and all other affections attended with congestion of the portal system, or torpidity of the hepatic vessels. The difficulty with which it is thrown from the stomach, renders it highly useful in some cases of obstinate vomiting, when other remedies are rejected. In the cases of children it is peculiarly valuable from the facility of its administration; and, in the febrile complaints to which they are subject, appears to exercise a curative influence, depending on some other cause than its mere purgative effect, and perhaps referrible to its action upon the liver. In the treatment of worms it is one of the most efficient remedies, acting probably not only as a purgative, but also as an irritant to the worms, either by its immediate in-

fluence, or that of the acrid bile which it causes to flow. The slowness and uncertainty of its action, and its liability to salivate if too long retained in the bowels, render it proper either to follow or combine it with other cathartics, in order to ensure its purgative effect. When given alone, it should be followed, if it do not operate in six or seven hours, by a dose of castor oil or sulphate of magnesia. The cathartics with which it is most frequently combined are jalap, rhubarb, aloes, scammony, colocynth, and gamboge. It is often added in small quantities to purgative combinations, with a view to its influence on the liver.

In very large doses, calomel is supposed by some to act directly as a sedative, and with this view has been given in yellow and malignant bilious fevers, violent dysentery, malignant cholera, &c. The quantities which have been administered in such affections, with asserted impunity and even advantage, are almost incredible. A common dose is one or two scruples, repeated every half hour, or hour, or less frequently, according to the circumstances of the case. We have had no experience in this mode of administering calomel.

It is sometimes used as an errhine in amaurosis, mixed with twice its weight of sugar, or other mild powder; and in the same combination is occasionally employed to remove specks and opacity of the cornea. For the latter purpose, Dupuytren recommended particularly the calomel prepared according to the plan of Mr. Jewell. Calomel is also sometimes employed externally in herpetic and other eruptions, in the shape of an ointment.

The dose as an alterative in functional derangement of the liver, is from half a grain to a grain every night, or every other night, followed in the morning, if the bowels are not opened, by a gentle saline laxative. When the stomach or bowels are very irritable, as in cholera and diarrhœa, from an eighth to a quarter of a grain may be given every hour or two, so as to amount to one or two grains in the course of the day. With a view to salivation, the dose is from half a grain to a grain three or four times a day, to be increased considerably in urgent cases. Sometimes, very minute doses, as the twelfth of a grain or less, given very frequently, so as to amount to the ordinary quantity in twenty-four hours, will operate more effectually as a sialagogue than larger doses. When large doses are given with this view, it is often necessary to combine them with opium. As a purgative, from five to fifteen grains or more may be given. Calomel has the peculiarity that its cathartic action is not increased in proportion to the dose, and enormous quantities have sometimes been given with impunity. In yellow fever, tropical dysentery, &c., from twenty grains to a drachm have been given, and repeated at short intervals, without producing hypercatharsis; but this practice is justifiable only in cases of extreme urgency, in which the constitutional action of mercury as well as purgation is indicated. Even in very small doses of not more than one, two, or three grains, calomel purges some individuals briskly. In these persons, large doses, though they do not proportionably increase the evacuation, often occasion spasmodic pain in the stomach and bowels. For children larger doses are generally required in proportion than for adults. Not less than from three to six grains should be given as a purge to a child two or three years old, and this quantity often fails to act on the bowels, unless assisted by castor oil or some other cathartic. Calomel may be given in pill made with gum Arabic and syrup, or in powder mixed with syrup or molasses.

HYDRARGYRI CYANURETUM. *U.S.* *Cyanuret of Mercury. Bicyanuret of Mercury. Prussiate of Mercury.*

"Take of Ferrocyanuret of Iron [Prussian blue] *four ounces;* Red Oxide of Mercury *three ounces,* or *a sufficient quantity;* Distilled Water *three pints.* Put

the Ferrocyanuret of Iron and three ounces of the Oxide of Mercury, previously powdered and thoroughly mixed, into a glass vessel; and pour upon them two pints of the Distilled Water. Then boil the mixture, stirring constantly; and, if at the end of half an hour the blue colour remain, add small portions of the Oxide of Mercury, continuing the ebullition until the mixture becomes of a yellowish colour; after which, filter it through paper. Wash the residue in the remainder of the Distilled Water, and filter as before. Mix the solutions, and evaporate till a pellicle appears; then set the liquor aside that crystals may form. To purify the crystals, dissolve them in distilled water, filter and evaporate the solution, and set it aside to crystallize." *U. S.*

The object of the above process is to present cyanogen and mercury to each other under favourable circumstances for combination. The compound formed consists of two eqs. of cyanogen, and one of mercury. It is, therefore, properly speaking, a bicyanuret. As Prussian blue is a compound of cyanogen and iron, the reaction which occurs is a case of double decomposition, resulting in the formation of bicyanuret of mercury, and a mixture of the protoxide and sesquioxide of iron. The reaction may be thus expressed; $2Fe_7Cy_9$ and $9HgO_2 = 9HgCy_2$ and $6FeO$ and $4Fe_2O_3$. This formula would be exact, if nothing remained but the oxides of iron; but in the residuum cyanogen appears to be present in an unknown state of combination.

Winckler prepares the bicyanuret of mercury by the following process. Mix 15 parts of ferrocyanuret of potassium in powder with 13 parts of concentrated sulphuric acid, and 100 parts of water. Distil the mixture to dryness into a receiver containing 30 parts of water. The ferrocyanuret is decomposed, bisulphate of potassa is formed in the retort, and hydrocyanic acid distils over. Of the acid thus obtained reserve a portion, and mix the remainder with 16 parts of red oxide of mercury in fine powder, and stir the mixture till the odour of hydrocyanic acid has entirely disappeared. Then decant the liquor, and add, for the purpose of saturating it, the portion of acid that had been reserved. This process yields 12 parts of bicyanuret. If the liquor were not treated with free hydrocyanic acid after having acted on the red oxide, it would probably contain some of this oxide in excess, and when evaporated would yield, instead of the bicyanuret, a peculiar salt, composed of the bicyanuret and the red oxide, which crystallizes in small acicular crystals.

Properties, &c. Cyanuret of mercury is permanent in the air, and crystallizes in anhydrous right square prisms, which are sometimes transparent, but usually white and opaque. It has a disagreeable styptic taste. It is but sparingly soluble in alcohol, but dissolves readily in cold water, and much more abundantly in hot. When acted on by muriatic acid, hydrocyanic acid is evolved, recognisable by its odour, and bichloride of mercury is left, which is wholly volatilizable by heat. When heated it yields cyanogen, and a black matter is left containing globules of mercury. It acts on the animal economy as a potent poison. In medicinal doses it excites nausea, vomiting, and not unfrequently ptyalism, but does not produce epigastric pain like corrosive sublimate. It has been occasionally used as a remedy in syphilis; and in the treatment of that disease it is preferred by some practitioners to corrosive sublimate, on account of its not giving rise to pain, and not being decomposed by alkalies and certain organic matters. The dose is from a sixteenth to an eighth of a grain. Its composition has been already given. B.

HYDRARGYRI IODIDUM. *U. S., Lond.* HYDRARGYRI IODIDUM VIRIDE. *Dub. Iodide of Mercury. Green Iodide of Mercury. Protiodide of Mercury.*

"Take of Mercury *an ounce;* Iodine *five drachms;* Alcohol *a sufficient quantity.* Rub the Mercury and Iodine together, adding sufficient Alcohol to form

a soft paste, and continue the trituration till the globules disappear. Then dry the Iodide in the dark, with a gentle heat, and keep it in a well stopped bottle protected from the light." *U. S.*

The *London* and *Dublin Colleges* make this iodide by the foregoing formula.

This process for forming the protiodide of mercury is a case of simple combination, the alcohol facilitating the union by dissolving the iodine. It may also be prepared by precipitation, by adding a solution of iodide of potassium to one of the nitrate of protoxide of mercury; but, as it is difficult to prepare the nitrate of the protoxide, without being mixed with some nitrate of deutoxide, the protiodide, when thus obtained, is apt to be contaminated with biniodide. A better way is to decompose calomel by iodide of potassium, in which case protiodide of mercury and chloride of potassium are formed, the latter of which may be removed by washing. The formula recommended by M. Boutigny is to mix twenty-nine drachms of calomel with twenty of pulverized iodide of potassium in a glass mortar, and to pour upon the mixture twelve ounces of boiling distilled water. After cooling, the liquid is decanted, and the precipitate washed on a filter with distilled water, and dried in the shade. (*Amer. Jour. of Pharm.*, viii. 326, from the *Bull. Gén. de Thérap.*)

Properties. Iodide of mercury is in the form of a yellowish-green powder, insoluble in water, alcohol, or solution of chloride of sodium, but soluble in ether. Its sp. gr. is 7·75. It sometimes contains biniodide, which may be separated by washing it with alcohol, as recommended by Mialhe. When exposed to the light it is partially decomposed, and becomes of a dark-olive colour. If quickly and cautiously heated, it sublimes in red crystals which afterwards become yellow. It is composed of one eq. of mercury 202, and one of iodine 126·3=328·3. Its formula is HgI.

Medical Properties and Uses. Iodide of mercury has been given in scrofula and scrofulous syphilis. The dose is a grain daily, gradually increased to three or four. It should never be given at the same time with iodide of potassium, which converts it immediately into biniodide and metallic mercury. (Mialhe, *Journ. de Pharm.*, 3e *sér.*, iv. 36.)

HYDRARGYRI IODIDUM RUBRUM. *U. S.*, *Dub.* HYDRARGYRI BINIODIDUM. *Ed.* *Red Iodide of Mercury. Biniodide of Mercury.*

"Take of Corrosive Chloride of Mercury *an ounce;* Iodide of Potassium *ten drachms;* Distilled Water *two pints.* Dissolve the Chloride of Mercury in a pint and a half, and the Iodide of Potassium in half a pint of the Distilled Water, and mix the solutions. Collect the precipitate upon a filter, and, having washed it with distilled water, dry it with a moderate heat, and keep it in a well stopped bottle." *U. S.*

The *Dublin* formula is substantially the same as that of the U. S. Pharmacopœia; the same proportion of the reacting salts being taken, and a similar mode of proceeding prescribed.

"Take of Mercury *two ounces;* Iodine *two ounces and a half;* Concentrated Solution of Muriate of Soda *a gallon* [Imp. meas.]. Triturate the Mercury and Iodine together, adding occasionally a little rectified spirit till a uniform red powder be obtained. Reduce the product to fine powder, and dissolve it in the solution of Muriate of Soda with the aid of brisk ebullition. Filter, if necessary, through calico, keeping the funnel hot. Wash and dry the crystals which form on cooling." *Ed.*

In the U.S. and Dub. processes for forming biniodide or red iodide of mercury, a double decomposition takes place between corrosive sublimate and iodide of potassium, resulting in the formation of chloride of potassium which remains in solution, and biniodide of mercury which precipitates. The precipitate is soluble in the reacting salts, and hence a loss of part of it is incurred by an

excess of either. It is best, however, to have a slight excess of the iodide of potassium, which is furnished by the proportion taken in the formulæ; as then the decomposition of the whole of the corrosive sublimate is insured, and any contamination of the biniodide by it prevented. The process of the Edinburgh College is the same in principle as that for obtaining the protiodide, described in the last article; namely, the simple combination of the ingredients by trituration with the aid of alcohol, a double proportion of iodine, of course, being taken; but after the red powder is obtained, it is treated with a boiling solution of common salt, which dissolves the biniodide to the exclusion of any contaminating protiodide; and the solution, thus obtained, on cooling, deposits the pure biniodide in crystals.

According to Dublanc, biniodide of mercury may be made economically by pouring 1000 parts of alcohol of 38° Cartier (sp. gr. 0·825) on 100 of mercury, contained in a matrass, and adding, from time to time, 10 parts of dry iodine, until 120 parts have been consumed. By agitation each portion of iodine is successively made to combine with the mercury, a result which is known to have taken place by the alcohol resuming its transparency. To complete the reaction, 4 additional parts of iodine are added, which, being more than enough to convert the whole of the mercury into biniodide, permanently colours the alcohol. The alcohol is now poured off, and the deposited biniodide washed with a little concentrated alcohol and dried. The alcohol poured off is reserved for future operations. (*Journ. de Pharm.*, March, 1849.)

Properties. Biniodide of mercury is a scarlet-red powder, of the sp. gr. 6·3, insoluble in water, but soluble in alcohol, and in solutions of iodide of potassium, chloride of sodium, and many of the mercurial salts. As obtained by the Edinburgh process, it is in splendid crimson acicular crystals. When heated it fuses readily into a yellow liquid, and sublimes in yellow rhombic scales, which become red on cooling. Biniodide of mercury is a dimorphous substance, having a different crystalline form in its red and yellow states. It forms definite compounds with the iodides of the alkalifiable metals. The compound formed with iodide of potassium has been used as a medicine. (See *Iodohydrargyrate of Potassium*, in the *Appendix.*) Biniodide of mercury consists of one eq. of mercury 202, and two of iodine 252·6=454·6. Its formula is HgI_2. It combines with the protiodide, so as to form a yellow *sesquiodide*, represented by the formula $HgI+HgI_2$, or Hg_2I_3.

Medical Properties and Uses. Biniodide of mercury is a powerful irritant poison. It has been used in similar diseases with the protiodide, namely, in scrofula and syphilis, but is much more active. The dose is a sixteenth of a grain, gradually increased to a fourth, given in pill, or dissolved in alcohol. M. Cazenave has found it the best topical application he has used in lupus. He applies it in thin layers, every six or eight days, to small portions of the ulcerated surface at a time, in the form of a caustic ointment, made of equal parts of the iodide, oil, and lard. The application produces violent pain, and gives rise to a sharp inflammation which soon terminates, leaving the ulcer in an improved condition, with a tendency to cicatrize smoothly, and on a level with the surrounding skin. (*Ann. de Thérap.*, A. D. 1852, p. 175.)

Off. Prep. Liquor Arsenici et Hydrargyri Iodidi; Unguentum Hydrargyri Iodidi Rubri. B.

HYDRARGYRI OXIDUM NIGRUM. *U.S.* *Black Oxide of Mercury.*

"Take of Mild Chloride of Mercury [calomel], Potassa, each, *four ounces;* Water *a pint.* Dissolve the Potassa in the Water, and, when the dregs have subsided, pour off the clear solution. To this add the Mild Chloride of Mercury, and stir them constantly together till the Black Oxide is formed. Having

poured off the supernatant liquor, wash the Black Oxide with distilled water, and dry it with a gentle heat." *U. S.*

This preparation has been abandoned by the London and Dublin Colleges in the last edition of their Pharmacopœias (1851 and 1850). The object of the U. S. process is to obtain the protoxide or black oxide of mercury, which was at one time believed to be the active constituent of those preparations in which the metal is minutely divided by trituration. The calomel is completely decomposed by the solution of potassa; its chlorine uniting with potassium to form chloride of potassium, which remains in solution, and the mercury with the oxygen of the potassa to form protoxide of mercury, which subsides. More potassa is employed than by calculation would seem to be requisite; but it has been ascertained by experiment that a considerable excess is necessary for the complete decomposition of the calomel. The use of the officinal solution of potassa is preferable, on the score of economy, to that of a solution extemporaneously prepared from the caustic alkali. In order to ensure the success of the process, the calomel, very finely levigated, should be rubbed quickly with the alkaline solution in a mortar; and the resulting oxide should be dried in the dark with a very gentle heat, as it is decomposed by the agency both of light and of an elevated temperature. For the same reason it should be preserved in an opaque bottle. This mode of preparing the black oxide of mercury was introduced into use by Mr. Donovan.

The oxide may also be prepared by decomposing a solution of the nitrate of protoxide of mercury by the solution of potassa. This nitrate may be obtained by treating twenty parts of mercury with eighteen parts of nitric acid of 25° Baumé, adding, when nitrous vapours cease to rise, ten parts of warm distilled water, boiling for a short time, decanting the clear liquor, and setting it aside to crystallize. The mother-waters by evaporation will furnish a new product of crystals of nitrate of protoxide. (Ratier, *Pharm. Franc.*) The former London Pharmacopœia prepared this oxide by decomposing calomel with lime-water; but it is extremely difficult to effect a complete decomposition in this way, and the preparation was consequently almost always mixed with calomel. The process recently abandoned by the Dublin College was the same essentially as the present one of the U. S. Pharmacopœia. The preparation, officinal in a former Dublin Pharmacopœia under the name of *Pulvis Hydrargyri Cinereus*, made by adding carbonate of ammonia to a solution of mercury in heated nitric acid, was a mixture of subnitrate of mercury and ammonia with the protoxide of mercury.

Properties, &c. As first prepared, this oxide is greenish-black; but as found in the shops it is almost always of an olive colour, owing, it is supposed, to the chemical changes which it undergoes. It is inodorous, tasteless, and insoluble in water and alkaline solutions; and consists of one eq. of mercury 202, and one of oxygen 8=210. On exposure to light or heat it is decomposed, one part assuming the metallic state, in consequence of the loss of its oxygen, which converts another part into the deutoxide. The preparation, therefore, becomes a mixture of the protoxide, the deutoxide, and metallic mercury, with which calomel is sometimes associated, in consequence of the incomplete decomposition of that originally employed in the process. By a strong heat it is completely dissipated, and metallic globules are sublimed. When pure it is soluble in acetic and nitric acids, and entirely insoluble in muriatic acid, which forms with it water and calomel. If it contain the deutoxide, this will be dissolved by muriatic acid, and may be detected in the solution by the production of a white precipitate with water of ammonia, and a yellow one with solution of potassa. Calomel, if present, may be discovered by boiling the powder with a solution of potassa, thus forming chloride of potassium, which, when the solution is saturated with nitric acid, will afford a white precipitate of chloride of silver on the addition of nitrate of silver. (*Phillips.*)

Medical Properties and Uses. The black oxide is alterative, sialagogue, and purgative. It may be employed for the same purposes with calomel, over which, however, it has not in our hands exhibited any superiority, while, from the occasional presence of the deutoxide, it must be liable to operate harshly. Dr. B. H. Coates, of this city, informs us that he uses it habitually as a mercurial, and finds it to answer an excellent purpose. The idea under which it was introduced into use, that it was the basis of the blue pill, is probably erroneous. Made into an ointment with lard according to the process of Donovan, it may be applied externally with good effect in bringing the system under the mercurial influence. (See *Unguentum Hydrargyri.*) Its dose as an alterative is one-fourth or half of a grain daily, as a sialagogue from one to three grains two or three times a day, given in the form of pill. It was employed by Mr. Abernethy for mercurial fumigation; the patient being placed, covered with under garments, in a vapour-bath, and exposed for fifteen or twenty minutes to the vapours arising from two drachms of the oxide, put upon heated iron within the bath. W.

HYDRARGYRI OXIDUM RUBRUM. *U. S.*, *Ed.* Hydrargyri Nitrico-oxidum. *Lond.* Hydrargyri Oxydum Rubrum. *Dub.* *Red Oxide of Mercury. Red Precipitate.*

"Take of Mercury *thirty-six ounces;* Nitric Acid *eighteen fluidounces;* Water *two pints;* Dissolve the Mercury, with a gentle heat, in the Acid and Water previously mixed together, and evaporate to dryness. Rub the dry mass into powder, and heat it in a very shallow vessel till red vapours cease to rise." *U. S.*

"Take of Mercury *three pounds;* Nitric Acid *eighteen fluidounces;* Distilled Water *two pints* [Imperial measure]. Mix, and apply a gentle heat till the mercury is dissolved. Boil down the solution, and rub the residue into powder. Put this into a very shallow vessel; then apply a gentle fire, and gradually increase it, till red vapour ceases to rise." *Lond.*

"Take of Mercury *eight ounces;* Diluted Nitric Acid (D. 1·280) *five fluidounces* [Imperial measure]. Dissolve half of the Mercury in the Acid with the aid of a moderate heat; and continue the heat till a dry salt is formed. Triturate the rest of the Mercury with the salt till a fine uniform powder be obtained; heat the powder in a porcelain vessel and constantly stir it, till acid fumes cease to be discharged." *Ed.*

"Take of Pure Mercury *eight ounces* [avoirdupois]; Pure Nitric Acid *three fluidounces;* Distilled Water *six* [*fluid*]*ounces.* In the Acid, diluted with the Water, digest the Mercury, using at first a very gentle heat, but, when the action has ceased, finally boiling for a few minutes; and, having decanted the solution, evaporate to dryness. Let the residuum, first reduced to powder, be transferred to a shallow cast-iron pot with a flat bottom, and loosely covered by a fire-tile lid; and in this let it be exposed to the heat of a slow fire until red vapours cease to be given off. The heat must now be withdrawn, and, when the pot has cooled, its contents should be transferred to bottles." *Dub.*

In these processes the mercury is first oxidized at the expense of a portion of the nitric acid, the remainder of which unites with the oxidized metal to form either the nitrate of the deutoxide of mercury, or a mixture of this with the nitrate of the protoxide. The resulting mass when exposed to a strong heat is decomposed, giving out red nitrous fumes, and assuming successively a yellow, orange, and brilliant purple-red colour, which becomes orange-red on cooling. These changes are owing to the gradual separation and decomposition of the nitric acid, by the oxygen of which the protoxide of mercury, if any be present, is converted into deutoxide, while nitric oxide gas escapes, and takes the form of nitrous acid vapour on contact with the air. The deutoxide of mercury is left behind; but in general not entirely free from the nitrate, which cannot be wholly decomposed by heat, without endangering the decomposition of the oxide

itself, and the volatilization of the metal. The preparation is, in common language, called *red precipitate*. The name of *red oxide of mercury*, by which it is now designated in most of the Pharmacopœias, is appropriate; as the nitrate of mercury exists in it merely as an incidental impurity; and there is no occasion to distinguish the preparation from the pure deutoxide obtained by calcining mercury, the latter not being recognised as officinal, and perhaps never employed.

In the preparation of this mercurial, various circumstances influence in some measure the nature of the product, and must be attended to, if we desire to procure the oxide with that fine bright orange-red colour, and shining scaly appearance, which are usually considered desirable. Among these circumstances is the condition of the nitrate of mercury submitted to calcination. According to Gay-Lussac, it should be employed in the form of small crystalline grains. If previously pulverized, as directed in the officinal processes, it will yield an orange-yellow powder; if it be in the state of large and dense crystals, the oxide will have a deep-orange colour. Care must also be taken that the mercury and acid be free from impurities. It is highly important that sufficient nitric acid be employed fully to saturate the mercury. M. Payssé, who paid great attention to the manufacture of red precipitate, recommended 70 parts of nitric acid from 34° to 38° Baumé, to 50 parts of mercury. This, however, is an excess of acid. We have been told by a skilful practical chemist of Philadelphia that he has found, by repeated experiment, 7 parts of nitric acid of 35° Baumé, to be sufficient fully to saturate 6 parts of mercury. Less will not answer, and more would be useless. It is not necessary that the salt should be removed from the vessel in which it is formed; and it is even asserted that the product is always more beautiful when the calcination is performed in the same vessel. A matrass may be used with a large flat bottom, so that an extended surface may be exposed, and all parts heated equally. The metal and acid having been introduced, the matrass should be placed in a sand-bath, and covered with sand up to the neck. The solution of the mercury should be favoured by a gentle heat, which should afterwards be gradually increased till red vapours make their appearance, then maintained as equably as possible till these vapours cease, and at last slightly elevated till oxygen gas begins to escape. This may be known by the increased brilliancy with which a taper will burn if placed in the mouth of the matrass, or by its rekindling if partially extinguished. Too high a temperature must be carefully avoided, as it decomposes the oxide, and volatilizes the mercury. At the close of the operation, the mouth of the vessel should be stopped, and the heat gradually diminished, the matrass being still allowed to remain in the sand-bath. These last precautions are said to be essential to the fine red colour of the preparation. It is best to operate upon a large quantity of materials, as the heat may be thus more steadily and uniformly maintained. The direction of the Edinburgh College to rub a portion of mercury with the nitrate before decomposing it, renders the process more economical; as the nitric acid which would otherwise be dissipated is thus employed in oxidizing an additional quantity of the metal.

As the process is ordinarily conducted in chemical laboratories, the nitrate of mercury is decomposed in shallow earthen vessels, several of which are placed upon a bed of sand in the chamber of an oven or furnace, provided with a flue for the escape of the vapours. Each vessel may conveniently contain ten pounds of the nitrate. There is always loss in the operation thus conducted.

In the former Dublin Pharmacopœia, under the name of *Hydrargyri Oxydum Rubrum*, a preparation was officinal, called by the elder chemists *hydrargyrum præcipitatum per se*, or *precipitate per se*, and sometimes *calcined mercury*, made by exposing the metal to a heat near its boiling point, or about 600° F., in a matrass with a broad bottom and narrow mouth. The vapours rising were con-

densed in the upper part of the vessel; and a circulation was thus kept up within it, during which the mercury slowly combined with oxygen, being converted first into a black and then into a red powder. But the process was very slow, requiring several weeks for the complete oxidation of the metal; and, as the product, which was the pure deutoxide, had no peculiar virtues to recommend it over the oxide procured in the ordinary mode, it has been very properly discarded by the Dublin College. The oxide made in this way is in minute, sparkling, crystalline scales, of a deep-red colour, becoming still deeper by heat.

The same oxide of mercury, prepared by precipitation, was recognised in the former London Pharmacopœia by the name of *Hydrargyri Binoxidum* or *binoxide of mercury*. It was made by adding solution of potassa to a solution of bichloride of mercury, and differed from the preceding only in containing some water. It was an orange-red impalpable powder, having the same properties essentially as the present officinal red oxide.

Properties, &c. Red precipitate, when well prepared, has a brilliant red colour, with a shade of orange, a shining scaly appearance, and an acrid taste. It is very slightly soluble in water, of which Dr. Barker found 1000 parts to take up only 0·62 of the oxide. Dr. Christison found 1 part of the oxide to be dissolved by about 7000 parts of boiling water, and the solution to give a black precipitate with sulphuretted hydrogen. Nitric and muriatic acids dissolve it without effervescence. It yields oxygen when heated, and at a red heat is decomposed and entirely dissipated. It is essentially the deutoxide (peroxide) of mercury, consisting of one equivalent of the metal 202, and two of oxygen 16=218; but, in its ordinary state, it always contains a minute proportion of nitric acid, probably in the state of subnitrate. According to Brande, when rubbed and washed with a solution of potassa, edulcorated with distilled water, and carefully dried, it may be regarded as nearly pure deutoxide. It is said to be sometimes adulterated with brickdust, red lead, &c.; but these may be readily detected, as the oxide of mercury is wholly dissipated if thrown upon red-hot iron. The disengagement of red vapours, when it is heated, indicates the presence of nitrate of mercury. The same or some other saline impurity would be indicated, should water, in which the oxide has been boiled, afford a precipitate with lime-water.

Medical Properties and Uses. This preparation is too harsh and irregular in its operation for internal use; but is much employed externally as a stimulant and escharotic, either in the state of powder or of ointment. In the former state it is sprinkled on the surface of chancres, and indolent, flabby, or fungous ulcers; and, mixed with 8 or 10 parts of finely powdered sugar, is sometimes blown into the eye to remove opacity of the cornea. The powder should be finely levigated. The ointment is officinal.

Off. Prep. Hydrargyri Cyanuretum; Unguentum Hydrargyri Oxidi Rubri.

W.

HYDRARGYRI PERNITRATIS LIQUOR. *Dub.* *Solution of Pernitrate of Mercury. Acid Nitrate of Mercury. Acid Binitrate of Deutoxide of Mercury.*

"Take of Pure Mercury *two ounces* [avoirdupois]; Pure Nitric Acid *one fluid-ounce and a half* [Imp. meas.]; Distilled Water *one ounce and a half* [avoird.]. In the Acid, first diluted with the Water, dissolve the Mercury, with the application of heat, and evaporate the solution to the bulk of two ounces and a half [Imp. meas.]." *Dub.*

In the process for making this new officinal of the Dublin Pharmacopœia of 1850, mercury is dissolved, with the assistance of heat, in an excess of nitric acid, and there is formed an acid binitrate of deutoxide of mercury, which is brought to a determinate bulk by evaporation. Thus, the proportion of nitric

acid employed is sufficient not only to deutoxidize the mercury and generate a bisalt, but to furnish an excess of acid. The binitrate of the deutoxide of mercury must be viewed as the neutral salt of that oxide; and if this salt were exclusively formed, it may be presumed that three eqs. of mercury would require eight of nitric acid; two eqs. of the acid being broken up into nitric oxide and oxygen in oxidizing the mercury, and the remaining six uniting with the three eqs. of deutoxide formed, producing three eqs. of binitrate. In the formula, however, more than ten eqs. of nitric acid are taken to three of mercury; and, consequently, sufficient acid is furnished to form an acid salt. This solution forms a dense and very caustic liquid, containing from twelve to fifteen per cent. of acid in excess.

Medical Properties. This preparation is frequently used in Europe, and has been employed to some extent in this country, as a caustic application to malignant ulcerations and cancerous affections. It has been used by Biett in lupus, by Bennet and others in ulceration of the neck of the uterus, and by Recamier in cancer. It is applied by means of a camel's hair brush to the diseased surface, which is then covered with lint, moistened with the solution. The parts touched immediately become white, the surrounding parts inflame, and in a few days a yellow scab is formed, which gradually falls off. Sometimes the application produces salivation. When it is desirable to avoid this result, the cauterized part should be washed with water immediately after the application of the caustic. B.

HYDRARGYRI SULPHAS. *Dub.* *Sulphate of Mercury.*

"Take of Quicksilver of Commerce *ten ounces* [avoirdupois]; Oil of Vitriol of Commerce *six fluidounces* [Imp. meas.]. Place the Quicksilver and Oil of Vitriol in a porcelain capsule, and apply heat until effervescence ceases, and nothing remains but a white and dry crystalline salt." *Dub.*

Mercury is not acted on by cold sulphuric acid; but, when boiled with an excess of this acid to dryness, it is deutoxidized at the expense of part of the acid, sulphurous acid being copiously evolved; and the deutoxide formed unites with the undecomposed portion of the sulphuric acid, so as to form the bisulphate of the deutoxide of mercury, which is the sulphate of the Dublin College.

Sulphate of mercury, as obtained by a separate formula, is peculiar to the Dublin Pharmacopœia; but it is formed as the first step of the processes of the other Pharmacopœias for preparing corrosive sublimate, calomel, and turpeth mineral. The adoption of a separate formula and distinct officinal name for this salt is certainly a convenience; as it obviates the necessity of repeating the directions for obtaining the same substance in several distinct formulæ. On account of its important uses, it requires to be made on a large scale by the manufacturing chemist; and the process is generally performed in a cast-iron vessel, which should be conveniently arranged for the escape and decomposition of the sulphurous acid fumes, which otherwise become a serious nuisance to the neighbourhood. The best way to effect this purpose is to allow them to pass off through a very lofty chimney, mixed with abundance of coal smoke.

Properties, &c. Sulphate of mercury is in the form of a white saline mass. It consists of two eqs. of acid 80 and one of deutoxide of mercury 218=298. It has no medical uses.

Off. Prep. Calomelas; Sublimatum Corrosivum. B.

HYDRARGYRI SULPHAS FLAVUS. *U.S.* *Yellow Sulphate of Mercury.* *Turpeth Mineral.*

"Take of Mercury *four ounces;* Sulphuric Acid *six ounces.* Mix them in a glass vessel, and boil by means of a sand-bath till a dry white mass remains. Rub this into powder, and throw it into boiling water. Pour off the supernatant

liquor, and wash the yellow precipitated powder repeatedly with hot water; then dry it." *U. S.*

By referring to the articles on corrosive sublimate and calomel, it will be found that the peculiar salt which is generated by boiling sulphuric acid with mercury to dryness, is directed to be made as the first step for obtaining these chlorides; and here it is perceived that in preparing turpeth mineral, the same salt is again directed to be formed. We have already stated that this salt is the bisulphate of the deutoxide of mercury. When thrown into boiling or even warm water it is instantly decomposed, and an insoluble salt is precipitated, which is the turpeth mineral. According to Berzelius, turpeth mineral is a basic sesquisulphate of the deutoxide of mercury, and the supernatant solution contains a supersulphate, consisting of six eqs. of acid and one of base. The same composition for turpeth mineral is given by Gay-Lussac; and its accuracy has been recently verified by an analysis of Sir Robert Kane, of Dublin. (See *Pharm. Journ. and Trans.* for August, 1842.) The composition above given of turpeth mineral implies the decomposition of four eqs. of the bisulphate of the deutoxide, and the manner in which the reaction takes place is shown by the following equation; $4(HgO_2,2SO_3)$=turpeth mineral, $3HgO_2,2SO_3$, and supersulphate of mercury, $HgO_2,6SO_3$.

Properties, &c. Yellow sulphate of mercury is in the form of a powder of a lemon-yellow colour, and possessing a somewhat acrid taste. It dissolves in 2000 parts of cold water, and in about 600 of boiling water. When exposed to a moderate heat, it becomes first red and afterwards brownish-red, but regains its original colour on cooling. (*Barker.*) At a red heat it is decomposed and dissipated, sulphuric acid being evolved, and metallic globules sublimed. It was originally called *turpeth* mineral, from the resemblance of its colour to that of the root of *Ipomæa Turpethum.*

Medical Properties and Uses. Turpeth mineral is alterative, and powerfully emetic and errhine. As an alterative, it has been given in leprous disorders and glandular obstructions. It has been employed with benefit as an emetic, repeated every few days, in chronic enlargement of the testicle. It operates with great promptness, and sometimes excites ptyalism. Dr. Hubbard, of Maine, considers it a valuable medicine, in cases in which the equalizing and revulsive effect of emesis is alone desired, apart from any cathartic operation, which he has never known it to produce. He recommends it highly as an emetic in croup, on the ground of its promptness and certainty, and of its not producing catharsis, or the prostration caused by antimony. The dose for a child two years old is two or three grains, repeated in fifteen minutes, if it should not operate. As an errhine, it has been used with advantage in chronic ophthalmia, and in diseases of the head; and it sometimes produces salivation when thus employed. The dose as an alterative is from a quarter to half a grain; as an emetic from two to five grains. When employed as an errhine, one grain may be mixed with five of starch or powdered liquorice root.

Turpeth mineral, in an over-dose, acts as a poison. A case of death in a boy aged sixteen, caused by swallowing a drachm, is reported by Dr. Letheby in the *London Medical Gazette,* for March, 1847. B.

HYDRARGYRI SULPHURETUM NIGRUM. *U. S.* *Black Sulphuret of Mercury. Ethiops Mineral.*

"Take of Mercury, Sulphur, each, *a pound.* Rub them together till all the globules disappear." *U. S.*

Mercury and sulphur have a strong affinity for each other; as is shown by the fact, that, when they are triturated together in quantities, the mixture grows hot, cakes, and exhales a sulphureous odour. During the trituration, the mixture

should be sprinkled from time to time with a little water or alcohol, to prevent the dust from rising, which exposes the operator to serious inconvenience. When rubbed together in equal weights, as directed in the formula, they are supposed to unite chemically; but the proportion of sulphur is much greater than is necessary to form a definite compound. Only two sulphurets of mercury have been admitted by the generality of chemists, the protosulphuret, and the bisulphuret or cinnabar; but the quantity of sulphur directed in the process is much more than sufficient to form even the latter. Thus, it still remains an unsettled point, what is the exact nature of the officinal black sulphuret, or *ethiops mineral.* Mr. Brande, from his experiments, considers it to be the bisulphuret mixed with sulphur. Thus he found that, when boiled repeatedly in a solution of potassa, sulphur was dissolved, and a black insoluble powder was left, which sublimed without decomposition, and yielded a substance having all the characters of cinnabar.

Ethiops mineral is sometimes obtained by melting sulphur in a crucible, and adding to it an equal weight of mercury; but, when thus prepared, the sulphur is apt to become acidified, and the preparation to acquire an activity which does not belong to it when obtained by trituration. According to C. Vogler, a better method than that by trituration for obtaining ethiops mineral, is to agitate for two hours four ounces of mercury with an ounce of finely powdered flowers of sulphur in a strong stoppered bottle, capable of holding from twelve to sixteen ounces, and then to add another ounce of sulphur at intervals, continuing the agitation until no mercury can be distinguished with the naked eye. Finally, two ounces more of sulphur are added, and the mixture shaken, until the metal cannot be detected with a lens. The advantages of this method over that by trituration are that it consumes less time, is more easy of execution, and less injurious to health. (*Journ. de Pharm.* for September 1848.)

Properties, &c. Black sulphuret of mercury is a heavy, tasteless, insoluble, black powder. When exposed to heat, it becomes of a dark-violet colour, emits the excess of sulphur in sulphurous acid fumes, and sublimes in brilliant red needles without residue. If charcoal be present, it will remain behind. When well prepared, no globules of mercury are discernible in it when viewed with a magnifier; and, if rubbed on a gold ring, it should not communicate a white stain. Ivory black is detected in it by throwing a small portion on a red-hot iron, when a white matter (phosphate of lime) will be left behind. Adulteration by sulphuret of antimony is shown, if muriatic acid, boiled on a portion of the powder, acquires the property of causing a precipitate of oxychloride of antimony when added to water. According to the views of Mr. Brande, ethiops mineral consists of one eq. of bisulphuret of mercury, mixed with about ten and a half eqs. of sulphur in excess.

Medical Properties. Ethiops mineral is supposed to be alterative, and as such is sometimes prescribed in glandular affections and cutaneous diseases. It has been given in scrofulous swellings, occurring in children; and from the mildness of its operation is considered well suited to such cases. The dose generally given is from five to thirty grains, repeated several times a day; but it has often been administered in much larger doses, without producing any obvious impression on the system. The late Dr. Duncan stated that he had given it in doses of several drachms, for a considerable length of time, with scarcely any effect. Ethiops mineral is very little used as a medicine. The London and Dublin Colleges, in the recent editions of their Pharmacopœias, have omitted it. B.

HYDRARGYRI SULPHURETUM RUBRUM. *U. S.* Hydrargyri Bisulphuretum. *Lond.* Cinnabaris. *Ed.* *Red Sulphuret of Mercury. Bisulphuret of Mercury. Cinnabar.*

"Take of Mercury *forty ounces;* Sulphur *eight ounces.* Mix the Mercury with the melted Sulphur over the fire; and, as soon as the mass begins to swell,

remove the vessel from the fire, and cover it with considerable force, to prevent combustion; then rub the mass into powder, and sublime." *U. S.*

The *London* and *Edinburgh Colleges* take *two pounds* of mercury and *five ounces* of sulphur, and treat them as in the U. S. process.

Mercury and sulphur, when heated together, unite with great energy, and a product is obtained, which by sublimation becomes the red or bisulphuret of mercury. In order to render the combination more prompt, the sulphur is first melted; and the addition of the mercury should be made gradually, while the mixture is constantly stirred. Dr. Barker recommends the addition of the metal by straining it upon the melted sulphur through a linen cloth, whereby it falls in the form of a shower, in a minutely divided state. When the temperature has arrived at a certain point, the combination takes place suddenly with a slight explosion, attended by the inflammation of the sulphur, which must be extinguished by covering the vessel. A black mass will thus be formed, containing generally an excess of sulphur, which, before the sublimation is performed, should be got rid of by gently heating the matter, reduced to powder, on a sand-bath. The sublimation is best performed, on a small scale, in a loosely stopped glass matrass, which should be placed in a crucible containing sand, and, thus arranged, exposed to a red heat. The equivalent quantities for forming this sulphuret, are 32 of sulphur, and 202 of mercury.

Preparation on the Large Scale. Cinnabar is seldom or never prepared on a small scale, being made in large quantities for the purposes of the arts. In Holland, where it is principally manufactured, the sulphur is melted in a cast iron vessel, and the mercury is added in a divided state, by causing it to pass through chamois leather. As soon as the combination has taken place, the iron vessel is surmounted by another, into which the cinnabar is sublimed. In proportion as the quantity of the materials employed in one operation is greater, will the product have a finer tint. It is also important in the manufacture to use the materials pure, and to drive off any uncombined sulphur which may exist in the mass, before submitting it to sublimation.

Properties, &c. Red sulphuret of mercury is in the form of heavy, brilliant, crystalline masses, of a deep-red colour and fibrous texture. It is inodorous and tasteless, and insoluble in water and alcohol. It is not acted on by nitric, muriatic, or cold sulphuric acid, or by solutions of the caustic alkalies; but it is soluble in nitromuriatic acid, on account of the free chlorine which the mixed acid contains. When heated with potassa, it yields globules of mercury. In the open air it is decomposed by heat, the sulphur becoming sulphurous acid, and the mercury being volatilized. In close vessels at a red heat it sublimes without decomposition, and condenses in a mass composed of a multitude of small needles. When duly levigated, it furnishes a powder of a brilliant red colour, and in this state constitutes the paint called *vermilion.* It occurs native, and forms the principal ore of mercury, and that from which the metal is exclusively extracted. It should not be purchased in powder; as, in that state, it is sometimes adulterated with red lead, dragon's blood, or chalk. If red lead be present, acetic acid, digested with it, will yield a yellow precipitate (iodide of lead) with iodide of potassium. Dragon's blood may be detected by alcohol, which will take up the colouring matter of this vegetable product, if present; and, if chalk be mixed with it, effervescence will be excited on the addition of an acid. This sulphuret is composed of one eq. of mercury 202, and two of sulphur 32=234.

Medical Properties and Uses. Cinnabar was formerly considered to be alterative and anthelmintic, but is at present seldom given internally. It is sometimes employed in the way of fumigation, as a rapid sialagogue, in venereal ulcers of the nose and throat, in cases in which it is an object of importance to bring the system under the influence of mercury in the shortest possible time. The

dose for internal exhibition is from ten grains to half a drachm, in the form of electuary or bolus. When used by fumigation, half a drachm may be thrown on a red-hot iron, and the fumes inhaled as they arise. These consist of sulphurous acid gas and mercurial vapour, the former of which must prove highly irritating to the patient's lungs. A better substance for mercurial fumigation is the black oxide of mercury. B.

HYDRARGYRUM AMMONIATUM. *U. S.* HYDRARGYRI AMMONIO-CHLORIDUM. *Lond., Dub.* HYDRARGYRI PRECIPITATUM ALBUM. *Ed. Ammoniated Mercury. White Precipitate.*

"Take of Corrosive Chloride of Mercury *six ounces;* Distilled Water *a gallon;* Solution of Ammonia *eight fluidounces.* Dissolve the Corrosive Chloride of Mercury in the Water, with the aid of heat, and to the solution, when cold, add the Solution of Ammonia, frequently stirring. Wash the precipitate till the washings become tasteless, and dry it." *U. S.*

The *London* and *Edinburgh* processes are essentially the same as the above.

"Take of Corrosive Sublimate *one ounce* [avoirdupois]; Solution of Ammonia *nine fluidrachms* [Imp. meas.]; Distilled Water *one pint* [Imp. meas.]. Dissolve the Corrosive Sublimate in the Water, with the aid of a gentle heat, pour the Ammonia into the solution, and, having stirred the mixture well, collect the precipitate on a filter, and wash it with warm distilled water, until the liquid which passes through ceases to give a precipitate when dropped into an acid solution of nitrate of silver. Lastly, dry the product at a temperature not exceeding 212°." *Dub.*

All the Pharmacopœias now agree in obtaining white precipitate by precipitating a solution of corrosive sublimate by ammonia. When ammonia, in slight excess, is added to a cold solution of corrosive sublimate, muriate of ammonia is formed in solution, and the white precipitate of the Pharmacopœias is thrown down. The precipitate is washed, according to the U. S. formula, until the washings become tasteless, and not until the powder is tasteless as directed by the London College; because the powder itself is sapid. The matter washed away is muriate of ammonia and the excess of ammonia employed; and hence the washings, agreeably to the directions of the Dublin formula, are tested with an acid solution of nitrate of silver. According to Sir Robert Kane, white precipitate has a composition corresponding to one eq. of protochloride of mercury, united with one eq. of a compound represented by one eq. of ammonia, *minus* one eq. of hydrogen. To this compound, represented by NH_2, he has given the name of *amidogen*, the *amide* of some chemists. The reaction may be thus explained. Two eqs. of ammonia are decomposed into one eq. of ammonium (NH_4) and one of amide (NH_2); and one eq. of corrosive sublimate is resolved into one eq. of chlorine and one of calomel. The chlorine unites with the ammonium and remains in solution as chloride of ammonium (muriate of ammonia), and the calomel precipitates with the amide as white precipitate. In symbols the reaction is thus denoted; $2NH_3$ and $HgCl_2 = NH_4Cl$ and $HgCl,NH_2$. For an explanation of what is meant by *ammonium*, see *page* 81. The analysis of Kane agrees virtually with those of Guibourt and Hennell; for Guibourt's results, minus the elements of one eq. of water, and Hennell's, minus the elements of two eqs. of the same liquid, give exactly the constituents found by Kane.

Properties, &c. Ammoniated mercury is in powder or pulverulent masses, perfectly white, insoluble in water and alcohol, decomposed by boiling water, and having a taste, at first earthy and afterwards metallic. It dissolves without effervescence in muriatic acid. When heated with a solution of caustic potassa, it yields ammonia and becomes yellow. Exposed to a strong heat it is entirely dissipated, and resolved into nitrogen, ammonia, and protochloride of mercury or calomel. Adulteration with white lead, chalk, or sulphate of lime may be

detected by exposing a sample to a strong red heat, when these impurities will remain. Should starch be mixed with it, a charry residuum will be obtained on the application of heat. Lead may also be found by digesting the white precipitate with acetic acid, and testing the acetic solution with iodide of potassium, which, if lead be present, will give a yellow precipitate. The absence of protoxide of mercury is shown by its not being blackened when rubbed with lime-water. Ammoniated mercury is used only as an external application, in the form of ointment.

Off. Prep. Unguentum Hydrargyri Ammoniati; Unguentum Sulphuris Compositum. B.

HYDRARGYRUM CUM CRETÂ. *U. S.*, *Lond.*, *Ed.*, *Dub. Mercury with Chalk.*

"Take of Mercury *three ounces;* Prepared Chalk *five ounces.* Rub them together till all the globules disappear." *U. S.*, *Lond.*, *Ed.*

The *Dublin College* rubs *an ounce* of mercury with *two ounces* of prepared chalk, in a porcelain mortar until the globules cease to be visible, and the mixture acquires a uniform gray colour.

When mercury is triturated with certain dry and pulverulent substances, such as chalk or magnesia, it gradually loses its fluidity and metallic lustre, and assumes the form of a blackish or dark-gray powder. A similar change takes place when it is rubbed with viscid or greasy substances, such as honey or lard. The globules disappear, so as in some instances not to be visible even through a good lens; and the mercury is said to be extinguished. It was formerly thought that the metal was oxidized in the process. At present, the change is generally attributed to the mechanical division of the metal, which in this state is supposed to be capable of acting on the system. There is good reason, however, to believe that in this, as in all the analogous preparations of mercury, in which the metal is extinguished by trituration, a very small portion is converted into protoxide, while by far the greater part remains in the metallic state.

Mercury with chalk is a grayish powder, in which globules of mercury can generally be seen with the aid of a microscope; as the metal can scarcely be completely extinguished with chalk alone by any length of trituration. Mr. Jacob Bell found that, by powerfully pressing it, a considerable quantity of metal was separated in the form of globules. Mr. Phillips states that the extinguishment of the mercury is greatly accelerated by the addition of a little water. Mr. Stewart, of Baltimore, proposed the following process, by which he stated that the preparation might be completed in a short time, so that no globules should be visible with a powerful lens. Three ounces of mercury and six ounces of resin are to be rubbed together for three hours; five ounces of chalk are to be added, and the trituration continued for an hour; the mixture is then to be heated with alcohol so as to dissolve the resin; and the remaining powder is to be dried on bibulous paper, and well rubbed in a mortar. (*Am. Journ. of Pharm.*, xv. 162.) But Professor Procter has shown that the preparation thus made contains deutoxide of mercury, and is, therefore, injuriously harsh in its operation. (*Am. Journ. of Pharm.*, xxii. 113.) It is said that the precipitated black oxide is sometimes added with a view to save time in the trituration. But this must be considered as an adulteration, until it can be shown that the same oxide exists, in the same proportion, in the preparation made according to the officinal directions. Dr. Edward Jenner Coxe, of New Orleans, has found that the extinguishment of the mercury may be effected much more speedily than in the ordinary manner, by putting the ingredients into a quart bottle, to be well corked, and kept in constant agitation till the object is attained. This mode of proceeding was suggested to him by Mr. W. Hewson, of Augusta, Ga. (*Am. Journ. of Pharm.*, xxii. 317.) The mercury contained in this preparation is

volatilized by heat. The remaining chalk is dissolved by dilute acetic acid, and the solution is not coloured by sulphuretted hydrogen. The presence of any probable metallic impurity may be detected in this way.

Medical Properties and Uses. Mercury with chalk is a very mild mercurial, similar in its properties to the blue pill, but much weaker. It is sometimes used as an alterative, particularly in the complaints of children attended with deficient biliary secretion, indicated by white or clay-coloured stools. The chalk is antacid, and, though in small quantity, may sometimes be a useful accompaniment of the mercury in diarrhœa. Eight grains of the preparation, according to the U. S., London, and Edinburgh Pharmacopœias, contain three grains of mercury. The dose is from five grains to half a drachm twice a day. Two or three grains is the dose for a child. It should not be given in pill with substances which become hard on keeping; as the contraction of the mass presses together the particles of mercury, which, in time, appear in globules in the interior of the pill. W.

HYDRARGYRUM CUM MAGNESIÂ. *Dub. Mercury with Magnesia.*

The *Dublin College* prepares this with *an ounce* of pure mercury and *two ounces* of carbonate of magnesia in the same manner as directed for the preparation of mercury with chalk. (See *Hydrargyrum cum Cretâ.*)

This preparation has the same virtues with the preceding, but may be preferably used in the complaints of children attended with constipation. W.

INFUSA.

Infusions.

These are aqueous solutions obtained by treating with water, without the aid of ebullition, vegetable products which are only partly soluble in that liquid. The water employed may be hot or cold, according to the objects to be accomplished. Infusions are generally prepared by pouring boiling water upon the vegetable substance, and macerating in a lightly closed vessel till the liquid cools. The soluble principles are thus extracted more rapidly, and, as a general rule, in a larger proportion than at a lower temperature. Some substances, moreover, are dissolved in this manner, which are nearly or quite insoluble in cold water. A prolonged application of heat is in some instances desirable; and this may be effected by placing the vessel near the fire. Cold water is preferred, when the active principle is highly volatile, when it is injured by heat, or when any substance of difficult solubility at a low temperature exists in the vegetable, which it is desirable to avoid in the infusion. A longer continuance of the maceration is necessary in this case; and, in warm weather, there is sometimes danger that spontaneous decomposition may commence before the process is completed. When a strong infusion is required, the *process of percolation* may be advantageously resorted to. (See *pages* 782 and 789.) The water employed should be free from saline impurities, which frequently produce precipitates, and render the infusion turbid. Fresh river, rain, or distilled water is usually preferable to that of pumps or springs.

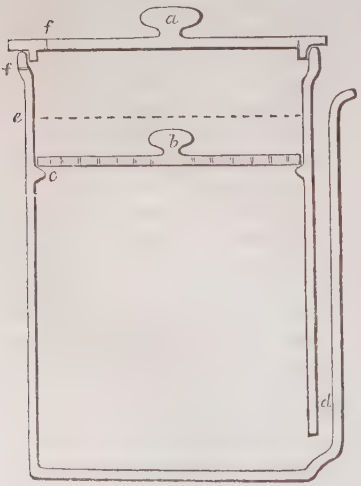
The substance to be acted on should be sliced or bruised, or employed in the state of powder; but this last condition is seldom requisite, and is always inconvenient, as it requires that the infusion should be filtered through paper in order completely to separate the undissolved portion. In other cases, it is sufficient to strain through fine linen or muslin. When, however, percolation or displacement is resorted to, the substance should be more or less finely powdered. Infusions are usually prepared in glazed earthenware or porcelain vessels fitted

with covers. Mr. Brande suggests the use of clean metallic vessels, which, when finely polished, retain the heat for a greater length of time; but they are also more liable to chemical alteration, and may sometimes injuriously affect the preparation. Vessels of block-tin are generally well adapted for the purpose.*

As infusions do not keep well, especially in warm weather, they should be made extemporaneously and in small quantities. In this country they are usually prepared in families, and the propriety of their introduction into the Pharmacopœia has been doubted; but it is desirable to have certain fixed standards for the convenience of the medical practitioner; and it is sometimes convenient to direct infusions from the apothecary, for whose guidance officinal formulæ are necessary. Physicians would, indeed, find their advantage in more frequently directing them from the shops, instead of leaving their preparation to the carelessness or want of skill of the attendants upon the sick. For a mode of preserving infusions, the reader is referred to the introductory observations, page 785. By making very concentrated infusions, as suggested by Mr. Donovan, with a mixture of three parts of water and one of alcohol, they may be kept for a long time, and when used can be diluted with water to the proper strength. Thus, if made four times as strong as the officinal infusion, they may be diluted with three measures of water. The proportion of alcohol would thus be very small; but it would still frequently be medically injurious; and infusions should never be prepared in this way unless with the cognizance of the prescriber.

Mr. Battley, of London, has introduced a new set of preparations, which he calls *inspissated infusions*, the advantages of which are that the virtues are extracted by cold water, are not injured by heat used in the evaporation, are in a concentrated state, and are not injured by time. To prepare them he macerates the material, coarsely powdered, bruised, or finely sliced, in twice its weight of cold distilled water, pressing the solid matter into the liquid repeatedly by a rammer or the hand; then allows the liquid to drain out, or expresses it in the

* *Alsop's infusion jar* affords a very neat and effectual method of making the hot infusions. It consists of an earthenware mug, represented in the marginal figure, with a spout (*d*) proceeding from the bottom, and placed closely to the side of the vessel to prevent fracture; a perforated plate or diaphragm (*b*), supported on a ledge (*c*), at about one-quarter or one-third of the height of the vessel from the top; and a lid (*a*), which may be fastened on by a string through holes (*ff*). The material to be submitted to infusion is placed on the perforated plate, and the hot water poured in so as cover it, the vessel having been previously warmed so as not to chill the liquid. As the water becomes impregnated, it acquires an increased specific gravity, and sinks to the bottom, its place being supplied by the unsaturated portion; and this circulation goes on until the whole of the soluble matter is extracted. In order to maintain a due warmth, the vessel may be placed upon a stove or an iron plate near the fire. The advantage of the process is that the material is subjected to the solvent power of the least impregnated portion of the menstruum. Such jars may now be had in Philadelphia. In order that the vessel may be adapted for the preparation of different quantities of infusions, it will be proper to have ledges arranged within at different heights, so that the diaphragm may be supported at any desirable point. The surface of the liquid (*e*) should of course always be above the medicinal substance placed upon the diaphragm. (See *Am. Journ. of Pharm.*, viii. 89.)



case of highly absorbent substances; and repeats the process, with an amount of water equal to that which has been separated, until the strength is exhausted. Four or six hours maceration is usually sufficient. The infusion is then to be concentrated by evaporation at a temperature not exceeding 160° to the sp. gr. 1·200, and as much alcohol is to be added as will make its sp. gr. 1·100. These preparations are very analogous to the *fluid extracts* already treated of. As a general rule it would probably be preferable to prepare the infusion by the process of percolation. The inspissated infusions must be diluted when administered. The presence of alcohol, though in small quantity, would in some instances be a serious objection. (*Pharm. Journ. and Trans.*, x. 129.)

As we have already treated of the chemical relations and medical properties of the substances used in infusion, it would be useless repetition to enlarge upon these points in the following details. We shall touch upon them only in cases of peculiar interest, or where changes requiring particular notice may grow out of the nature of the process. W.

INFUSUM ANGUSTURÆ. *U. S.* Infusum Cusparіæ. *Lond., Ed. Infusion of Angustura Bark.*

"Take of Angustura Bark, bruised, *half an ounce;* Boiling Water *a pint.* Macerate for two hours in a covered vessel, and strain." *U. S.*

The *London College* directs *five drachms* to *a pint* [Imperial measure] of boiling distilled water; the *Edinburgh*, *five drachms* to *a pint* [Imp. meas.] of boiling water; and both proceed as above.

The dose of the infusion is two fluidounces, repeated every two, three, or four hours. W.

INFUSUM ANTHEMIDIS. *U.S., Lond., Ed., Dub. Infusion of Chamomile.*

"Take of Chamomile *half an ounce;* Boiling Water *a pint.* Macerate for ten minutes in a covered vessel, and strain." *U. S.*

The *London College* orders *five drachms* of the flowers to *a pint* [Imperial measure] of boiling distilled water, and proceeds as above; the *Edinburgh*, *five drachms* to *a pint* [Imp. meas.] of boiling water, and infuses for twenty minutes; the *Dublin*, *half an ounce* [avoirdupois] of the flowers and *twelve* [*fluid*]*ounces* of boiling water, and infuses for fifteen minutes.

The infusion of chamomile has the odour and taste of the flowers. It affords precipitates with gelatin, yellow Peruvian bark, sulphate of iron, tincture of chloride of iron, nitrate of silver, corrosive chloride of mercury, and the acetates of lead. (*London Dispensatory.*) As a tonic it is given cold, in the dose of two fluidounces several times a day. To assist the operation of emetic medicines it should be administered in the tepid state, and in large draughts. The infusion prepared by maceration in cold water is more grateful to the palate and stomach than that made with boiling water, but is less efficient as an emetic. W.

INFUSUM ARMORACIÆ. *U. S.* Infusum Armoraciæ Compositum. *Lond. Infusion of Horse-radish.*

"Take of Horse-radish [fresh root], sliced, Mustard [seed], bruised, each, *an ounce;* Boiling Water *a pint.* Macerate for two hours in a covered vessel, and strain." *U. S.*

The *London College* macerates *an ounce* of the root, and *an ounce* of the seeds in *a pint* [Imp. meas.] of boiling distilled water, in a covered vessel, for two hours, and strains; then adds *a fluidounce* of compound spirit of horse-radish.

This infusion is rendered turbid by the deposition of vegetable albumen, and in warm weather speedily runs into the putrefactive fermentation. It affords precipitates with the infusions of galls and Peruvian bark, with the alkaline carbonates, nitrate of silver, and corrosive chloride of mercury. (*London Dis-*

pensatory.) It has the stimulant properties of its two active ingredients, and is occasionally used in paralytic, scorbutic, and dropsical affections, attended with general debility. The dose is two fluidounces three or four times a day. W.

INFUSUM AURANTII COMPOSITUM. *Lond., Dub.* INFUSUM AURANTII. *Ed.* *Compound Infusion of Orange Peel.*

"Take of dried Orange Peel *half an ounce;* Lemon Peel *two drachms;* Cloves, bruised, *a drachm;* boiling Distilled Water *a pint* [Imperial measure]. Macerate for a quarter of an hour in a covered vessel, and strain." *Lond.*

The *Edinburgh* process differs from the above only in the use of boiling water not distilled, and in straining through linen or calico. The *Dublin College* takes *three drachms* [Dub. weight] of dried bitter orange peel, *half a drachm* [Dub. weight] of bruised cloves, and *half a pint* [Imp. meas.] of boiling water; and infuses for half an hour.

This infusion is given as a grateful stomachic, in the dose of two or three fluidounces. W.

INFUSUM BUCHU. *U. S., Lond., Dub.* INFUSUM BUCKU. *Ed.* *Infusion of Buchu.*

"Take of Buchu *an ounce;* Boiling Water *a pint.* Macerate for two hours in a covered vessel, and strain." *U. S.*

The *London College* takes *an ounce* of buchu and *a pint* [Imperial measure] of boiling distilled water, and macerates for four hours; the *Edinburgh*, the same quantities, and infuses for two hours; the *Dublin*, *half an ounce* (avoird.) of buchu and *half a pint* [Imp. meas.] of boiling water, and infuses for an hour.

This is the *Infusum Diosmæ* of former Pharmacopœias. It has the odour, taste, and medical virtues of the leaves, and affords a convenient method of administering the medicine. The dose is one or two fluidounces. W.

INFUSUM CAPSICI. *U. S.* *Infusion of Cayenne Pepper.*

"Take of Cayenne Pepper, in coarse powder, *half an ounce;* Boiling Water *a pint.* Macerate for two hours in a covered vessel, and strain." *U. S.*

This infusion is used chiefly as a gargle. It may, however, be given internally in the dose of half a fluidounce. W.

INFUSUM CARYOPHYLLI. *U. S., Lond., Ed., Dub.* *Infusion of Cloves.*

"Take of Cloves, bruised, *two drachms;* Boiling Water *a pint.* Macerate for two hours in a covered vessel, and strain." *U. S.*

The *London College* takes *three drachms* of cloves, and *a pint* [Imperial measure] of boiling distilled water; the *Edinburgh*, *three drachms* of cloves and *a pint* [Imp. meas.] of boiling water; and both proceed as above. The *Dublin College* takes *two drachms* [Dub. weight] of cloves, and *nine* [*fluid*]*ounces* of boiling water, and infuses for an hour.

The infusion of cloves affords precipitates with lime-water, and with the soluble salts of iron, zinc, lead, silver, and antimony. (*Phillips.*) The dose is about two fluidounces. W.

INFUSUM CASCARILLÆ. *U. S., Lond., Ed., Dub.* *Infusion of Cascarilla.*

"Take of Cascarilla, bruised, *an ounce;* Boiling Water *a pint.* Macerate for two hours in a covered vessel, and strain." *U. S.*

The *London College* directs *an ounce and a half* of bruised cascarilla, and *a pint* [Imperial measure] of boiling distilled water; the *Edinburgh*, the same quantities of the bark and of boiling water; and both proceed as above. The *Dublin College* takes *an ounce* [avoirdupois] of the bark, and *half a pint* [Imp. meas.] of boiling water, and infuses for an hour.

This infusion affords precipitates with lime-water, infusion of galls, nitrate of silver, acetate and subacetate of lead, sulphate of zinc, and sulphate of iron. (*London Dispensatory.*) The medium dose is two fluidounces. W.

INFUSUM CATECHU COMPOSITUM. *U. S.*, *Lond.*, *Dub.* INFUSUM CATECHU. *Ed.* *Compound Infusion of Catechu.*

"Take of Catechu, in powder, *half an ounce;* Cinnamon, bruised, *a drachm;* Boiling Water *a pint.* Macerate for an hour in a covered vessel, and strain." *U. S.*

"Take of Catechu, in powder, *six drachms;* Cinnamon, bruised, *a drachm;* boiling Distilled Water *a pint* [Imperial measure]. Macerate for an hour in a covered vessel, and strain." *Lond.*

"Take of Catechu, in powder, *six drachms;* Cinnamon, in powder, *one drachm;* Syrup *three fluidounces;* boiling Water *seventeen fluidounces.* Infuse the Catechu and Cinnamon with the Water for two hours, strain through linen or calico, and add the Syrup." *Ed.*

"Take of Catechu, in coarse powder, *three drachms* [Dub. weight]; Cinnamon bark, bruised, *half a drachm* [Dub. weight]; boiling Water *nine* [*fluid*]*ounces.* Infuse for one hour in a covered vessel, and strain." *Dub.*

This is an elegant mode of administering catechu. The dose is from one to three fluidounces, repeated three or four times a day, or more frequently. W.

INFUSUM CHIRETTÆ. *Ed.*, *Dub.* *Infusion of Chiretta.*

"Take of Chiretta *four drachms;* boiling Water *one pint* [Imperial measure]. Infuse for two hours, and strain through linen or calico." *Ed.*

"Take of Chiretta, bruised, *two drachms* [Dub. weight]; boiling Water *nine* [*fluid*]*ounces and a half.* Infuse for one hour in a covered vessel, and strain." *Dub.*

The dose of this simple bitter is from one to three fluidounces. W.

INFUSUM CINCHONÆ COMPOSITUM. *U. S.* *Compound Infusion of Peruvian Bark.*

"Take of Red Bark, in powder *an ounce;* Aromatic Sulphuric Acid *a fluidrachm;* Water *a pint.* Macerate for twelve hours, occasionally shaking, and strain.

"The Infusion may also be prepared from the same quantity of Red Bark, in coarse powder, by the process of displacement, in the manner directed for Infusion of Yellow Bark, *a fluidrachm* of Aromatic Sulphuric Acid being added to the Water with which the Bark is moistened." *U. S.*

This is an elegant and very efficient preparation. Water extracts from bark the kinates of quinia and cinchonia, but leaves behind the compounds which these principles form with the cinchonic red. The ordinary infusion, therefore, is rather feeble. But the addition of the acid ensures the solution of all or nearly all the active matter. We have been long in the habit of using this infusion, and have had reason to be satisfied with its efficacy. The second process more speedily and perhaps thoroughly exhausts the bark; but in this case a glass or porcelain percolator should be used. This preparation may also be made very advantageously with the yellow or Calisaya bark. It would be best that the bark should be macerated with the acidulated water some time before being introduced into the instrument. The medium dose of the infusion is two fluidounces, equivalent to a drachm of the bark. W.

INFUSUM CINCHONÆ FLAVÆ. *U. S.* INFUSUM CINCHONÆ. *Lond.*, *Ed.* *Infusion of Yellow Bark.*

"Take of Yellow Bark, bruised, *an ounce;* Boiling Water *a pint.* Macerate for two hours in a covered vessel, and strain.

"This infusion may also be prepared from the same quantity of Yellow Bark, in coarse powder, in the following manner. Having moistened the Bark thoroughly with Water, introduce it into a percolator, press it slightly, and pour Water upon its surface so as to keep it covered. So long as the liquid passes turbid, return it into the apparatus; then allow the filtration to continue until a pint of clear infusion is obtained." *U. S.*

"Take of Yellow Bark, bruised, *an ounce;* boiling Distilled Water *a pint* [Imp. meas.]. Macerate for two hours in a covered vessel, and strain." *Lond.*

"Take of any species of Cinchona, according to prescription, *one ounce* in powder; boiling Water *one pint* [Imp. measure]. Infuse for four hours in a covered vessel, and then strain through linen or calico." *Ed.*

Though the infusion with boiling water is more quickly prepared than the cold infusion, and therefore better adapted to cases of emergency, yet the latter is a more elegant preparation, not turbid like the former, and at least equally efficient. We, therefore, prefer the second process of the U. S. Pharmacopœia, provided it be skilfully conducted. Perhaps it would be better that the bark should be in moderately fine than in coarse powder.

The infusion of cinchona affords precipitates with the alkalies, alkaline carbonates, and alkaline earths; the soluble salts of iron, zinc, and silver; corrosive chloride of mercury, arsenious acid, and tartar emetic; gelatinous solutions; and various vegetable infusions and decoctions, as those of galls, chamomile, columbo, cascarilla, horse-radish, cloves, catechu, orange-peel, foxglove, senna, rhubarb, valerian, and simaruba. In some instances the precipitate occurs immediately, in others not for several hours. (*London Dispensatory.*) Few, however, of these substances diminish the efficacy of the infusion, as they do not affect the active principles. The alkalies, alkaline earths, and vegetable astringents are really incompatible. The same is said to be the case with tartaric and oxalic acids, and the soluble tartrates and oxalates. For an elaborate account of the chemical reactions of the infusions of different varieties of Peruvian bark see the *Am. Journ. of Pharm.*, ix. 128.

The infusion of cinchona may be advantageously administered in cases which require tonic treatment, but do not call for the full powers of the bark. The medium dose is two fluidounces, to be repeated three or four times a day, or more frequently in acute diseases. W.

INFUSUM CINCHONÆ PALLIDÆ. *Lond.* INFUSUM CINCHONÆ. *Dub., Ed. Infusion of Pale Bark.*

The *London College* prepares this in the manner directed for infusion of yellow bark. (See *Infusum Cinchonæ Flavæ.*] The *Edinburgh College* has only one infusion of bark, which it names *Infusum Cinchonæ*, and prepares from any one of the varieties in the manner directed for infusion of yellow bark. The *Dublin College* directs only this infusion of bark, which it prepares by infusing *an ounce* [avoirdupois] of pale bark, in coarse powder, in *half a pint* [Imperial measure] of boiling water for an hour, in a covered vessel, and then filtering through paper.

It is rather singular that the Dublin College should have selected the feeblest bark exclusively for this preparation. The remarks made in reference to the preparation of the infusion of yellow bark are applicable to this. W.

INFUSUM CINCHONÆ RUBRÆ. *U.S.* INFUSUM CINCHONÆ. *Ed. Infusion of Red Bark.*

"Take of Red bark, bruised, *an ounce;* Boiling Water *a pint.* Prepare the Infusion in the manner directed for Infusion of Yellow Bark." *U. S.* (See *Infusum Cinchonæ Flavæ.*)

The *Edinburgh* directions are also the same as those for infusion of yellow

bark, as it recognises no distinction between the three varieties in the preparation of the infusion.

The remarks made in relation to infusion of yellow bark are equally applicable to this. W.

INFUSUM CINCHONÆ SPISSATUM. *Lond. Inspissated Infusion of Peruvian Bark.*

"Take of Yellow Bark, coarsely powdered, *three pounds;* Distilled Water *six pints* [Imperial measure]; Rectified Spirit *a sufficient quantity.* Macerate the Bark in the manner directed in the preparation of Extract of Peruvian Bark [see *Extractum Cinchonæ, Lond.*], and strain. Mix the infusions, evaporate by means of a water-bath to one-fourth, and set apart that the dregs may subside. Pour off the clear liquor, and filter the rest. Then mix, and again evaporate till the sp. gr. of the liquor becomes 1·200. Into this, when cold, slowly drop the Spirit, so that three fluidrachms may be added for every fluidounce. Lastly, set the liquor aside for twenty days, that it may become entirely clear." *Lond.*

INFUSUM CINCHONÆ PALLIDÆ SPISSATUM. *Lond. Inspissated Infusion of Pale Bark.*

"Prepare this in the manner directed for Inspissated Infusion of Peruvian Bark." *Lond.* (See *Infusum Cinchonæ Spissatum.*)

These two inspissated infusions are made according to Mr. Battley's method, described under the general observations upon infusions (see *page* 1051). They are no doubt efficacious preparations of Peruvian bark; and the proportion of alcohol is scarcely sufficient to interfere with their use in most cases in which the bark or its preparations are prescribed. They might without violence be placed among the fluid extracts. We have had some of the "Infusum Cinchonæ Spissatum" prepared, and found that each ounce of the bark yielded very nearly two fluidrachms of the preparation, the dose of which, therefore, equivalent to a drachm of the bark would be fifteen minims, supposing the bark to be exhausted; but, as this is not the case, twenty minims may be considered as a medium dose. The preparation is a very dark, yet clear, and intensely bitter liquid. W.

INFUSUM COLOMBÆ. *U. S.* Infusum Calumbæ. *Lond., Ed., Dub. Infusion of Columbo.*

"Take of Columbo, bruised, *half an ounce;* Boiling Water *a pint.* Macerate for two hours in a covered vessel, and strain." *U. S.*

The *London College* directs *five drachms* of Columbo to *a pint* [Imperial measure] of boiling distilled water, and proceeds as above.

"Take of Calumba, in coarse powder, *half an ounce;* cold Water about *a pint* [Imperial measure]. Triturate the Calumba with a little of the Water, so as to moisten it thoroughly; put it into a percolator, and transmit cold Water till sixteen fluidounces of infusion be obtained." *Ed.*

"Take of Calumba Root, in coarse powder, *three drachms* [Dub. weight]; cold Water *nine* [*fluid*]*ounces.* Macerate for two hours and strain." *Dub.*

The infusion of columbo is apt to spoil very quickly, especially in warm weather. It has been generally supposed that the cold infusion would keep better than the hot, because it contains no starch. Mr. Thomas Greenish, however, upon comparing specimens of the two infusions, found that the spontaneous change began sooner in the cold than the hot, though the former was clearer. Columbo contains starch and albumen. Cold water extracts the latter without the former; hot water the former with comparatively little of the latter, which is partially coagulated by the heat. Both starch and albumen are liable to spontaneous change; but the former is much the more permanent of the two. Hence it is, according to Mr. Greenish, that the hot infusion keeps best. Indeed, he ascribes the change which takes place in the starch of the hot infusion chiefly to the agency of a

little albumen, which has escaped coagulation. According to these views, the best plan of preparing infusion of columbo is to exhaust the root with cold water, by which the starch is left behind, and then to heat the infusion to the boiling point in order to coagulate the albumen. (*Am. Journ. of Pharm.*, xviii. 141, from *Pharm. Journ.*) Upon comparing specimens of the cold and hot infusion, we have not found the results of Mr. Greenish fully confirmed. The cold infusion appeared to keep better than the hot. Nevertheless, the plan of preparing the infusion above proposed is probably the best. The infusion of columbo is not disturbed by salts of iron, and may be conveniently administered in connexion with them. The dose is two fluidounces three or four times a day. W.

INFUSUM DIGITALIS. *U. S.*, *Lond.*, *Ed.*, *Dub.* *Infusion of Foxglove.*

"Take of Foxglove [dried leaves] *a drachm;* Boiling Water *half a pint;* Tincture of Cinnamon *a fluidounce.* Macerate the Foxglove with the Water for two hours in a covered vessel, and strain; then add the Tincture of Cinnamon." *U. S.*

The *London College* takes *a drachm* of the dried leaves, *a fluidounce* of spirit of cinnamon, and *a pint* [Imperial measure] of boiling distilled water; macerates the leaves in the water for four hours; and, having strained the liquor, adds the spirit. The *Ed. College* takes *two drachms* of the leaves, *two fluidounces* of spirit of cinnamon, and *eighteen fluidounces* of boiling water; and, having macerated the leaves in the water for four hours, strains through linen or calico, and adds the spirit. The *Dub. College* takes *a drachm* [54·68 grains] of the dried leaves, and *nine* [*fluid*]*ounces* of boiling water, infuses for an hour, and strains.

The U. S. infusion is essentially the same with that employed by Withering. It affords precipitates with the sulphate of iron, acetate of lead, and infusion of Peruvian bark. (*London Dispensatory.*) The dose is usually stated at half a fluidounce, repeated twice a day under ordinary circumstances, every eight hours in urgent cases, until the system is affected. The proportion of digitalis is not half as great in the London preparation, and the dose, of course, is proportionably larger. It will not, however, escape the close observer, that the stated dose of digitalis in infusion is much larger than in substance, for which there does not appear to be a good reason. It might be safer to give only half the quantity, and increase if necessary. W.

INFUSUM ERGOTÆ. *Dub.* *Infusion of Ergot.*

"Take of Ergot of Rye, in coarse powder, *two drachms* [Dublin weight]; Boiling Water *nine* [*fluid*]*ounces.* Infuse for one hour in a covered vessel and strain." *Dub.*

The dose of this infusion is two fluidounces for a woman in labour. W.

INFUSUM EUPATORII. *U. S.* *Infusion of Thoroughwort.*

"Take of Thoroughwort [the dried herb] *an ounce;* Boiling Water *a pint.* Macerate for two hours in a covered vessel, and strain." *U. S.*

As a tonic, this infusion should be taken cold in the dose of two fluidounces three or four times a day, or more frequently; as an emetic and diaphoretic, in large tepid draughts. W.

INFUSUM GENTIANÆ COMPOSITUM. *U. S.*, *Lond.*, *Dub.* INFUSUM GENTIANÆ. *Ed.* *Compound Infusion of Gentian.*

"Take of Gentian, bruised, *half an ounce;* Orange peel [dried peel of the Seville orange], bruised, Coriander, bruised, each, *a drachm;* Diluted Alcohol *four fluidounces;* Water [cold] *twelve fluidounces.* First pour on the Diluted Alcohol, and, three hours afterwards, the Water; then macerate for twelve hours, and strain." *U. S.*

The above was copied from the *Edinburgh* formula, which differs only in having *four fluidounces* [Imperial measure] of proof spirit and *sixteen fluidounces* [Imp. meas.] of cold water.

The *London College* takes of sliced gentian and dried orange peel, each, *two drachms*, of [fresh] lemon peel *four drachms*, of boiling distilled water *a pint* [Imperial measure]; the *Dublin* takes of gentian and dried orange peel, each, *two drachms* [Dub. weight], and of boiling water *half a pint* [Imp. meas.]; both macerate for an hour in a covered vessel, and strain.

The U. S. and Edinburgh infusion differs materially from the London. The former has much more gentian in proportion to the solvent than the latter, and is therefore a much stronger bitter; while, by the use of cold instead of boiling water, less of the inert mucilaginous matter is extracted, and the addition of alcohol gives the preparation the character rather of a weak tincture than an infusion. The use of the diluted alcohol is to assist in dissolving the bitter principle, and at the same time to contribute towards the preservation of the infusion, which, without this addition, is very apt to spoil. The Dublin preparation is rather weaker than that of the U. S. Pharmacopœia, and is simply an infusion.

The dose of the U. S. infusion is a fluidounce, that of the preparation of the London College two or three fluidounces, to be repeated three or four times a day.

Off. Prep. Mistura Gentianæ Composita. W.

INFUSUM HUMULI. *U. S.* Infusum Lupuli. *Lond.* *Infusion of Hops.*

"Take of Hops *half an ounce;* Boiling Water *a pint.* Macerate for two hours in a covered vessel, and strain." *U. S.*

"Take of Hops *six drachms;* boiling Distilled Water *a pint* [Imperial measure]. Macerate for four hours in a covered vessel, and strain." *Lond.*

The dose of this infusion is one or two fluidounces. W.

INFUSUM JUNIPERI. *Dub.* *Infusion of Juniper.*

"Take of Juniper Berries, bruised, *one ounce* [avoirdupois]; Boiling Water *half a pint* [Imperial measure]. Infuse for one hour, in a covered vessel, and strain." *Dub.*

It will be found more convenient to prepare this infusion, as is generally done in this country, in the proportion of *an ounce* of the fruit, to *a pint* of boiling water. The whole quantity made may be taken in twenty-four hours, in doses of two or three fluidounces. W.

INFUSUM KRAMERIÆ. *U. S.*, *Lond.*, *Dub.* *Infusion of Rhatany.*

"Take of Rhatany, bruised, *an ounce;* Boiling Water *a pint.* Macerate for four hours in a covered vessel, and strain.

"This Infusion may also be prepared from the same quantity of Rhatany, in coarse powder, by the process of displacement, in the manner directed for the Infusion of Yellow Bark." *U. S.* (See *Infusum Cinchonæ Flavæ.*)

The *London College* takes *an ounce* of the root, and *a pint* [Imperial measure] of boiling distilled water, and macerates for four hours; the *Dublin* takes *half an ounce* [avoirdupois] to *nine* [*fluid*]*ounces*, and digests for an hour.

The infusion of rhatany would probably be more efficient, if prepared by the mode of percolation, with cold water, from the root in a state of moderately fine powder, as directed for infusion of Peruvian bark. The dose of the infusion is one or two fluidounces. W.

INFUSUM LINI COMPOSITUM. *U. S.*, *Lond.* INFUSUM LINI. *Ed.* *Compound Infusion of Flaxseed.*

"Take of Flaxseed *half an ounce;* Liquorice Root, bruised, *two drachms;* Boiling Water *a pint.* Macerate for two hours in a covered vessel, and strain." *U. S.*

The *London College* directs *six drachms* of flaxseed, *two drachms* of sliced fresh liquorice root, and *a pint* [Imperial measure] of boiling distilled water, and macerates for four hours; the *Edinburgh* directs the same except boiling water for boiling distilled water, and digests near the fire for four hours.

This is a useful demulcent drink in inflammatory affections of the mucous membrane of the lungs and urinary passages. It may be taken *ad libitum.* W.

INFUSUM MATICO. *Dub.* *Infusion of Matico.*

"Take of Matico Leaves, cut small, *half an ounce* [avoirdupois]; Boiling Water *half a pint* [Imperial measure]. Infuse for one hour in a covered vessel, and strain." *Dub.*

The dose of this infusion is two fluidounces. W.

INFUSUM MENTHÆ VIRIDIS. *Dub.* *Infusion of Spearmint.*

"Take of Spearmint, dried, and cut small, *three drachms* [Dublin weight]; Boiling Water *half a pint* [Imperial measure]. Infuse for fifteen minutes, in a covered vessel, and strain." *Dub.*

This is common mint tea, and may be taken *ad libitum.* W.

INFUSUM PAREIRÆ. *Ed.*, *Dub.* *Infusion of Pareira Brava.*

"Take of Pareira *six drachms;* Boiling Water *a pint* [Imperial measure]. Infuse for two hours, in a covered vessel, and then strain through linen or calico." *Ed.*

"Take of Pareira Root, bruised and torn into shreds, *half an ounce* [avoirdupois]; Boiling Water *nine* [*fluid*]*ounces.* Digest for one hour, in a covered vessel, and strain." *Dub.*

The infusion of Pareira brava is highly esteemed by some English practitioners as a remedy in irritation and chronic inflammation of the urinary passages, and has been found useful in catarrh of the bladder. The dose is one or two fluidounces. Brodie employed a *decoction* of the root, which he prepared by boiling half an ounce in three pints of water down to a pint, and gave in the quantity of from eight to twelve fluidounces daily. The London College has substituted the decoction for the infusion. W.

INFUSUM PRUNI VIRGINIANÆ. *U. S.* *Infusion of Wild-cherry Bark.*

"Take of Wild-cherry Bark, bruised, *half an ounce;* Water [cold] *a pint.* Macerate for twenty-four hours, and strain.

"This Infusion may also be prepared from the same quantity of Wild-cherry Bark, in coarse powder, by the process of displacement, in the manner directed for Infusion of Yellow Bark." *U. S.* (See *Infusum Cinchonæ Flavæ.*)

This is a peculiarly suitable object for officinal direction, as, in consequence of the volatile nature of one of its active ingredients, and for another reason before stated (see *page* 598), it is better prepared with cold water than in the ordinary mode. The infusion of wild-cherry bark is one of the preparations to which the process of percolation or displacement is well adapted. In this way the virtues of the bark can be more rapidly and thoroughly exhausted than by maceration alone. When properly made, it is beautifully transparent, has the colour of madeira wine, and the agreeable bitterness and peculiar flavour of the bark. The dose is two or three fluidounces three or four times a day, or more frequently when a strong impression is required. W.

INFUSUM QUASSIÆ. *U. S., Lond., Ed., Dub. Infusion of Quassia.*

"Take of Quassia, rasped, *two drachms;* Water [cold] *a pint.* Macerate for twelve hours, and strain." *U. S.*

The *London College* takes *two scruples* of quassia, sliced, and *a pint* [Imperial measure] of boiling distilled water; the *Edinburgh, a drachm* of quassia in chips, and *a pint* [Imp. meas.] of boiling water; both macerate for two hours. The *Dublin College* takes *a drachm* [54·68 grains] of the wood, and *eight* [*fluid*] *ounces and a half* of boiling water, and infuses for an hour.

The proportion of quassia directed in the London and Edinburgh Pharmacopœias is much too small. The London infusion contains the strength of only two grains of quassia in a fluidounce, and the Edinburgh three grains; while the dose of quassia in substance is from twenty grains to a drachm, and of the extract not less than five grains. We, therefore, prefer the proportions directed by our national Pharmacopœia Boiling water may be employed when it is desirable to obtain the preparation quickly; but cold water affords a clearer infusion. The dose is two fluidounces three or four times a day. W.

INFUSUM RHEI. *U. S., Lond., Ed., Dub. Infusion of Rhubarb.*

"Take of Rhubarb, bruised, *a drachm;* Boiling Water *half a pint.* Digest for two hours in a covered vessel, and strain." *U. S.*

"Take of Rhubarb, sliced, *three drachms;* boiling Distilled Water *a pint* [Imperial measure]. Macerate for two hours, in a covered vessel, and strain." *Lond.*

"Take of Rhubarb, bruised into coarse powder, *one ounce;* Spirit of Cinnamon *two fluidounces;* boiling Water *eighteen fluidounces.* Infuse the Rhubarb for twelve hours in the Water, in a covered vessel, add the Spirit, and strain through linen or calico." *Ed.*

"Take of Rhubarb, sliced, *three drachms* [Dublin weight]; boiling Distilled Water *a pint* [Imp. meas.]. Macerate for two hours, in a covered vessel, and strain." *Dub.*

In order that the rhubarb may be exhausted, it should be digested with the water near the fire, at a temperature somewhat less than that of boiling water. It is customary to add some aromatic, such as cardamom, fennel-seed, or nutmeg, which improves the taste of the infusion, and renders it more acceptable to the stomach. One drachm of either of these spices may be digested in connexion with the rhubarb.

This infusion may be given as a gentle laxative, in the dose of one or two fluidounces, every three or four hours, till it operates. It is occasionally used as a vehicle of tonic, antacid, or more active cathartic medicines. The stronger acids and most metallic solutions are incompatible with it. W.

INFUSUM ROSÆ COMPOSITUM. *U. S., Lond.* INFUSUM ROSÆ. *Ed.* INFUSUM ROSÆ ACIDUM. *Dub. Compound Infusion of Roses.*

"Take of Red Roses [dried petals] *half an ounce;* Boiling Water *two pints and a half;* Diluted Sulphuric Acid *three fluidrachms;* Sugar [refined] *an ounce and a half.* Pour the Water upon the Roses in a glass vessel; then add the Acid, and macerate for half an hour; lastly, strain the liquor, and add the Sugar." *U. S.*

The *London College* takes *three drachms* of dried red roses, *a fluidrachm and a half* of diluted sulphuric acid, *six drachms* of sugar, and *a pint* [Imperial measure] of boiling distilled water, and proceeds as above, except that it macerates for two hours instead of half an hour. The *Edinburgh* process corresponds with the London, except that boiling water is used instead of boiling distilled water, the maceration continues only for an hour, and the acid is added after the

maceration instead of before it. The *Dublin College* takes *two drachms* [Dub. weight] of the dried roses, *a fluidrachm* of the diluted acid, and *half a pint* [Imp. meas.] of boiling water; infuses the petals for an hour in the water, strains, and adds the acid.

The red roses serve little other purpose than to impart a fine red colour and a slight astringent flavour to the preparation, which owes its medicinal virtues almost exclusively to the sulphuric acid. It is refrigerant and astringent, and affords a useful and not unpleasant drink in hemorrhages and colliquative sweats. It is much used by British practitioners as a vehicle for saline medicines, particularly sulphate of magnesia, the taste of which it serves to cover. It is also employed as a gargle, usually in connexion with acids, nitre, alum, or tincture of Cayenne pepper. The dose is from two to four fluidounces. W.

INFUSUM SARSAPARILLÆ. *U. S.* *Infusion of Sarsaparilla.*

"Take of Sarsaparilla, bruised, *an ounce;* Boiling Water *a pint.* Digest for two hours in a covered vessel, and strain.

"This infusion may also be prepared from the same quantity of Sarsaparilla, in coarse powder, by the process of displacement, in the manner directed for Infusion of Peruvian Bark." *U. S.* (See *Infusum Cinchonæ Flavæ.*)

From the experiments of Soubeiran it appears that, by maceration in cold water for twenty-four hours, the active principle of sarsaparilla is extracted as effectually as by infusion in boiling water and digestion for two hours, and that in either case the infusion is stronger than the decoction; but the aqueous preparation which he found to possess most of the sensible properties of the root, was made by infusing the spirituous extract in water. In all his experiments, M. Soubeiran employed the same proportions of the root and of water. (*Journ. de Pharm.*, xvi. 43.) These observations correspond with those long since made by Hancock, and subsequently confirmed by Mr. T. J. Husband, of this city, so far as relates to the greater solvent power of spirit than of water over sarsaparilla. (*Am. Journ. of Pharm.*, xv. 6.) Water does not appear competent completely to exhaust sarsaparilla of its active principle, unless employed in very large proportion. Still the watery preparations made from the root are certainly not without efficacy; and the inference from the experiments of Soubeiran is, that it is of little consequence whether the infusion be made with hot or cold water, supposing time to be allowed in the latter case. It is probable that percolation, as directed by the U. S. Pharmacopœia in the second formula above given, will be found the most efficacious plan. The sarsaparilla should in this case be reduced to powder. From two to four fluidounces of the infusion may be taken three times a day. W.

INFUSUM SASSAFRAS MEDULLÆ. *U. S.* *Infusion of Sassafras Pith.*

"Take of Sassafras Pith *a drachm;* Water [cold] *a pint.* Macerate for three hours, and strain." *U. S.*

This infusion is much used as an application to the eye in inflammation of the conjunctiva. It may be used as a drink in inflammatory and febrile diseases, particularly inflammations of the mucous passages, *ad libitum.* W.

INFUSUM SENEGÆ. *Ed.* INFUSUM POLYGALÆ. *Dub.* *Infusion of Seneka.*

"Take of Senega *ten drachms;* boiling Water *one pint* [Imperial measure]. Infuse for four hours in a covered vessel, and strain." *Ed.*

The *Dublin College* digests *half an ounce* [avoirdupois] of the root in *nine* [*fluid*]*ounces* of boiling water, for *an hour*, and strains.

The efficacy of the officinal decoction of seneka has been proved by so long an experience, that we should be cautious in allowing it to be superseded by the

infusion on hypothetical grounds alone. The dose of the preparation is from *one to three fluidounces.* W.

INFUSUM SENNÆ. *U. S.*, *Ed.* INFUSUM SENNÆ COMPOSITUM. *Lond.*, *Dub.* *Infusion of Senna.*

"Take of Senna *an ounce;* Coriander, bruised, *a drachm;* Boiling Water *a pint.* Macerate for an hour in a covered vessel, and strain." *U. S.*

The *London College* orders *fifteen drachms* of senna, *four scruples* of bruised ginger, and *a pint* [Imperial measure] of boiling distilled water; the *Edinburgh*, *an ounce and a half* of senna, *four scruples* of ginger, and *a pint* [Imp. meas.] of boiling water; and the *Dublin*, *half an ounce* [avoirdupois] of senna, *half a drachm* [Dub. weight] of ginger, and *half a pint* [Imp. meas.] of boiling water. All macerate as above directed.

We decidedly prefer the formula of the U. S. Pharmacopœia. The proportions of senna directed by the London and Edinburgh Colleges are unnecessarily large; and coriander is a better addition than ginger to an infusion very often given in inflammatory affections. This infusion deposits, on exposure to the air, a yellowish precipitate, which is said to aggravate its griping tendency; it should, therefore, not be made in large quantities. It is customary to connect with it manna and some one of the saline cathartics, which increase its efficacy and render it less painful in its operation. The following is a good formula for the preparation of senna tea. Take of senna *half an ounce;* sulphate of magnesia, manna, each, *an ounce;* fennel-seed *a drachm;* boiling water *half a pint.* Macerate in a covered vessel till the liquid cools. One-third may be given for a dose, and repeated every four or five hours till it operates. Such a combination as this is called *the black draught* by English writers. The dose of the infusion of the U. S. Pharmacopœia is about four fluidounces.

Off. Prep. Mistura Gentianæ Composita. W.

INFUSUM SENNÆ COMPOSITUM. *Ed.* *Compound Infusion of Senna.*

"Take of Senna *one drachm;* Tamarinds *one ounce;* Coriander, bruised, *one drachm;* Muscovado [sugar] *half an ounce;* boiling Water *eight fluidounces.* Infuse for four hours, with occasional stirring, in a covered vessel not glazed with lead, and then strain through linen or calico.

"This infusion may be likewise made with twice or thrice the prescribed quantity of senna." *Ed.*

In this infusion, the unpleasant taste of the senna is covered by the acidity of the tamarinds and sweetness of the sugar. It is aperient and refrigerant, and is well adapted to febrile complaints when a laxative operation is desired. The dose is from two to four fluidounces. W.

INFUSUM SERPENTARIÆ. *U. S.*, *Lond.*, *Ed.* *Infusion of Virginia Snakeroot.*

"Take of Virginia Snakeroot *half an ounce;* Boiling Water *a pint.* Macerate for two hours in a covered vessel, and strain." *U. S.*

The *London College* employs *half an ounce* of the root with *a pint* [Imperial measure] of boiling distilled water, and macerates for four hours. The *Edinburgh* process differs from the London only in the use of boiling water instead of boiling distilled water.

This is the ordinary form in which serpentaria is employed. The dose is one or two fluidounces, repeated every two hours in low forms of fever, but less frequently in chronic affections. W.

INFUSUM SIMARUBÆ. *Ed.*, *Dub.* *Infusion of Simaruba.*

"Take of Simaruba, bruised, *three drachms;* boiling Water *a pint* [Imperial

measure]. Infuse for two hours in a covered vessel, and then strain through linen or calico." *Ed.*

The *Dublin College* infuses *two drachms* [Dublin weight] of the bark with *nine* [*fluid*]*ounces* of boiling water, for an hour, in a covered vessel, and strains.

This preparation is little used in the United States. The dose is two fluidounces. W.

INFUSUM SPIGELIÆ. *U. S.* *Infusion of Pinkroot.*

"Take of Pinkroot *half an ounce;* Boiling Water *a pint.* Macerate for two hours in a covered vessel, and strain." *U. S.*

The dose of this infusion, for a child two or three years old, is from four fluidrachms to a fluidounce; for an adult, from four to eight fluidounces, repeated morning and evening. A quantity of senna equal to that of the spigelia is usually added, in order to insure a cathartic effect. W.

INFUSUM TABACI. *U. S.* ENEMA TABACI. *Lond., Ed., Dub.* *Infusion of Tobacco.*

"Take of Tobacco *a drachm;* Boiling Water *a pint.* Macerate for an hour in a covered vessel, and strain." *U. S.*

The *London College* takes *a scruple* of tobacco, and *half a pint* [Imperial measure] of boiling distilled water, macerates for an hour, and strains. The *Edinburgh College* takes from *fifteen* to *thirty grains* of tobacco, and *eight fluidounces* of boiling water, infuses for half an hour, and strains. The *Dublin College* takes *a scruple* [18·22 grains], and *eight* [*fluid*]*ounces* of boiling water, infuses for an hour, and strains.

This is used only in the form of enema in strangulated hernia, obstinate colic, and retention of urine from spasm of the urethra. Only half of the pint of the U. S. infusion should be employed at once; and, if this should not produce relaxation in half an hour, the remainder may be injected. Fatal consequences have resulted from too free a use of tobacco in this way. W.

INFUSUM TARAXACI. *U. S.* *Infusion of Dandelion.*

"Take of Dandelion, bruised, *two ounces;* Boiling Water *a pint.* Macerate for two hours in a covered vessel, and strain." *U. S.*

This has been substituted in the U. S. Pharmacopœia for the decoction. The dose is a wineglassful two or three times a day, or oftener. W.

INFUSUM ULMI. *U. S.* *Infusion of Slippery Elm Bark.*

"Take of Slippery Elm Bark, sliced and bruised, *an ounce;* Boiling Water *a pint.* Macerate for two hours in a covered vessel, and strain." *U. S.*

This infusion may be used *ad libitum* as a demulcent and nutritious drink in catarrhal and nephritic diseases, and in inflammatory affections of the intestinal mucous membrane. W.

INFUSUM VALERIANÆ. *U. S., Lond., Dub.* *Infusion of Valerian.*

"Take of Valerian *half an ounce;* Boiling Water *a pint.* Macerate for an hour in a covered vessel, and strain." *U. S.*

The *London College* takes *half an ounce* of Valerian, and *a pint* [Imperial measure] of boiling distilled water, macerates for half an hour in a covered vessel, and strains. The *Dublin College* takes *two drachms* [Dub. weight] of valerian, and *nine* [*fluid*]*ounces* of boiling water, digests for an hour, and strains.

The dose of this infusion is two fluidounces, repeated three or four times a day, or more frequently. W.

INFUSUM ZINGIBERIS. *U. S.* *Infusion of Ginger.*

"Take of Ginger, bruised, *half an ounce;* Boiling Water *a pint.* Macerate for two hours in a covered vessel, and strain." *U. S.*

The dose of this infusion is two fluidounces. W.

IODINIUM.

Preparations of Iodine.

IODINIUM PURUM. *Dub. Pure Iodine.*

"Take of Iodine of Commerce *any convenient quantity.* Introduce it into a deep porcelain capsule of a circular shape, and, having covered this as accurately as possible with a glass matrass filled with cold water, apply to the capsule a water heat for the space of twenty minutes, and then, withdrawing the heat, permit the capsule to cool. Should the sublimate attached to the bottom of the matrass include acicular prisms of a white colour and pungent odour, let it be scraped off with a glass rod, and rejected. The matrass being now returned to its previous position, a gentle and steady heat (that of a gas-lamp answers well) is to be applied, so as to sublime the entire of the iodine. Upon now lifting off the matrass, the purified product will be found attached to its bottom. When separated, it should be immediately enclosed in a bottle furnished with an accurately ground stopper." *Dub.*

The Edinburgh College does not recognise purified iodine under a separate name, but gives the following directions for its purification.

"Iodine, as obtained in commerce, being almost always adulterated with variable proportions of water, and being consequently unfit for making pharmaceutical preparations of fixed and uniform strength, it must be dried by being placed in a shallow basin of earthenware in a small confined space of air with ten or twelve times its weight of fresh-burnt lime, till it scarcely adheres to the inside of a dry bottle." *Ed.*

In the Dublin process for the purification of iodine, a short preliminary sublimation by the heat of a water-bath is ordered, in which the bottom of a glass matrass filled with cold water is the refrigerator. The object of this is to separate any iodide of cyanogen that may happen to be present. This impurity is sometimes present in considerable amount. Klobach obtained from eighty pounds of commercial iodine, twelve ounces of this iodide, which is in the proportion of nearly one per cent. (*Chem. Gaz.*, April 15, 1850.) If the matrass, upon its removal, should have attached to its bottom white acicular crystals, these will consist of the iodide referred to, and must be rejected. The matrass having been replaced, heat is again applied until the whole of the iodine has sublimed, and attached itself to the cool bottom of the matrass. The Edinburgh process for purifying iodine is merely intended to separate water by the drying influence of quicklime. Water has sometimes been found to the extent of fifteen or twenty per cent. Its amount may be estimated by the method of M. Bolley, which consists in rubbing together, until the smell of iodine disappears, thirty grains of iodine with about two hundred and forty grains of mercury, in a weighed small porcelain dish, using a weighed small agate pestle. When complete combination has been effected, the whole is placed in a water-bath to dissipate the water. The loss of weight gives the amount of water in the iodine. (*Chem. Gaz.*, Mar. 15, 1853, p. 118.) The presence of water is not otherwise injurious than as it renders all the preparations of iodine weaker than they should be.

The U. S. and London Pharmacopœias give no directions for purifying iodine; but the iodine recognised is the pure substance, and not the commercial iodine, unless this should happen to be pure. The properties and tests of pure iodine have been given under the head of *Iodinium* in the first part of this work.

Off. Prep. Arsenici et Hydrargyri Hydriodatis Liquor; Ferri Iodidum; Hydrargyri Iodidum Viride; Potassii Iodidi Liquor Compositus; Potassii Iodidum; Sulphur Iodatum; Syrupus Ferri Iodidi; Tinctura Iodinii Composita; Unguentum Iodinii Compositum. B.

LIQUOR IODINII COMPOSITUS. *U. S.* IODINEI LIQUOR COMPOSITUS. *Ed.* *Compound Solution of Iodine.*

"Take of Iodine *six drachms;* Iodide of Potassium *an ounce and a half;* Distilled Water *a pint.* Dissolve the Iodine and Iodide of Potassium in the Water." *U. S.*

"Take of Iodine *two drachms;* Iodide of Potassium *an ounce;* Distilled Water *sixteen fluidounces* [Imp. meas.]. Dissolve the Iodide and Iodine in the Water with gentle heat and agitation." *Ed.*

In these solutions iodine is dissolved in water with the assistance of iodide of potassium. Iodine dissolves sparingly in water, but freely in a solution of that salt. In using iodide of potassium to render iodine more soluble in water, the iodide is generally taken in a quantity twice the weight of the iodine; and this is the proportion adopted in the U. S. formula. The *U. S.* solution corresponds in strength with Lugol's *concentrated* solution of iodine with iodide of potassium, and is intended to facilitate the administration of the combination in drops. The *Edinburgh* preparation is a weaker form of the same concentrated solution of iodine, in which the iodide of potassium is taken in a quantity four times the weight of the iodine, instead of twice its weight, the usual proportion adopted. On the assumption that 16 Imperial fluidounces are equal to the wine pint, and they are only 5 fluidrachms less, it will be found, on comparing the formulæ, that the Edinburgh solution is one-third as strong in iodine, and two-thirds as strong in iodide of potassium as that of the U. S. Pharmacopœia. The medicinal properties of these solutions depend mainly on the free iodine contained in them, by which their dose must be regulated, and not by the iodide of potassium. The dose of the U. S. solution is six drops, containing about a quarter of a grain of iodine, three times a day, given in four tablespoonfuls of sweetened water, and gradually increased. For children the dose to begin with is two drops. (See *page* 411.) The Edinburgh solution may be given in doses about three times as large. B.

LINIMENTA.

Liniments.

These are preparations intended for external use, of such a consistence as to render them conveniently applicable to the skin by gentle friction with the hand. They are usually thicker than water, but thinner than the ointments, and are always liquid at the temperature of the body. W.

LINIMENTUM ÆRUGINIS. *Lond.* *Liniment of Verdigris.*

"Take of Verdigris [Subacetate of Copper], in powder, *an ounce;* Vinegar *seven fluidounces;* Honey *fourteen ounces.* Dissolve the Verdigris in the Vinegar, and strain through linen; then gradually add the Honey, and boil down to the proper consistence." *Lond.*

It sometimes happens during the boiling of the acetic solution of the verdigris, that a red deposit rapidly forms, consisting of the red or suboxide of copper; and that, at the end of the process, little or none of the metallic salt remains in the preparation. This happens especially when granular honey is employed. (Harley, *Pharm. Journ. and Trans.*, xi. 357.) The change is owing to the decomposition of the oxide of copper by the grape sugar of the honey, converting it into the suboxide. The inference is that, in making the preparation, so as to fulfil the intentions of the original prescription, fresh liquid honey should be employed, which contains comparatively little glucose.

This is an external stimulant and escharotic, and was formerly called *Mel Ægyptiacum.* It is employed, either undiluted, or mixed with some mild oint-

ment, to destroy fungous granulations, or to repress their growth. In the latter state, it is a useful stimulant to flabby, indolent, and ill-conditioned ulcers, and, largely diluted with water, has been used as a gargle in venereal ulcerations of the mouth and throat. It is sometimes also applied undiluted to such ulcers in the fauces, by means of a camel's-hair brush. W.

LINIMENTUM AMMONIÆ. *U. S., Lond., Ed., Dub. Liniment of Ammonia. Volatile Liniment.*

"Take of Solution of Ammonia *a fluidounce;* Olive Oil *two fluidounces.* Mix them." *U. S.*

The *London* and *Edinburgh* processes agree with the above. The *Dublin College* directs *one fluidounce* of its solution of ammonia, and *three fluidounces* of olive oil.

The U. S., London, and Edinburgh Pharmacopœias agree at present in the strength of this liniment. In the preparation, the ammonia unites with the oil to form a soap, which is partly dissolved, partly suspended in the water, producing a white, opaque emulsion. The liniment is an excellent rubefacient, frequently employed in inflammatory affections of the throat, catarrhal and other pectoral complaints of children, and in rheumatic pains. It is applied by rubbing it gently upon the skin, or placing a piece of flannel saturated with it over the affected part. Should it occasion too much inflammation, it must be diluted with oil. W.

LINIMENTUM AMMONIÆ COMPOSITUM. *Ed. Compound Liniment of Ammonia.*

"Take of Stronger Aqua Ammoniæ (D. 0·880) [Stronger Solution of Ammonia] *five fluidounces;* Tincture of Camphor *two fluidounces;* Spirit of Rosemary *one fluidounce.* Mix them well together. This liniment may be also made weaker for some purposes with *three fluidounces* of Tincture of Camphor and *two* of Spirit of Rosemary." *Ed.*

This liniment is a very close imitation of Dr. Granville's *counter-irritant lotion.* Like that, it is of two strengths; the stronger containing five-eighths of its bulk of the ammoniacal solution, the weaker only five-tenths. They are nothing more than dilutions in different degrees of the officinal *Liquor Ammoniæ Fortior,* which is itself too powerful for convenient use. The tincture of camphor and spirit of rosemary can scarcely exercise, in this case, any peculiar therapeutical influence. These preparations are employed as prompt and powerful rubefacients, vesicatories, or escharotics, in various neuralgic, gouty, rheumatic, spasmodic, and inflammatory affections, in which strong and speedy counter-irritation is indicated. When mere rubefaction is desired, the weaker lotion may be used; and even for blistering or cauterizing, unless a very prompt effect is necessary. In the latter case the stronger lotion should be resorted to. They are applied by means of linen folded several times, or a thick piece of flannel saturated with the liniment. A convenient mode is to fill the wooden cover of a large pill or ointment box, an inch or two in diameter, with patent lint, saturate this with the liquid, and press it upon the part. The ammonia is thus prevented from escaping, and a definite boundary given to the inflammation. The application will generally produce rubefaction in from one to six or eight minutes, vesication in from three to ten minutes, and a caustic effect in a somewhat longer period. W.

LINIMENTUM AMMONIÆ SESQUICARBONATIS. *Lond. Liniment of Sesquicarbonate of Ammonia.*

"Take of Solution of Sesquicarbonate of Ammonia *a fluidounce;* Olive Oil *three fluidounces.* Shake them together until they are mixed." *Lond.*

In this, as in the liniment of ammonia, a liquid soap is formed; but the union between the oil and alkali is less perfect, and after a short time the soapy matter separates from the water. The preparation is therefore less elegant; and the end which it was intended to answer, of affording a milder rubefacient, may be obtained by diluting the liniment of ammonia with olive oil. W.

LINIMENTUM CALCIS. *U. S., Lond., Ed., Dub. Lime Liniment.*

"Take of Lime-water, Flaxseed Oil, each, *two fluidounces.* Mix them." *U. S.*

The *London College* directs *ten fluidounces*, each, of lime-water and olive oil; the *Dublin*, *two fluidounces*, each, of the same ingredients; the *Edinburgh*, *equal measures* of lime-water and flaxseed oil.

The lime forms a soap with the oil, of which there is a great excess, that separates upon standing. Olive oil, as directed by the London and Dublin Colleges, is often substituted for that of flaxseed; but possesses no other advantage than that of having a less unpleasant odour. This is a very useful liniment in recent burns and scalds. It is sometimes called *Carron oil*, from having been much employed at the iron works of that name in Scotland. It is recommended to be applied upon carded cotton. W.

LINIMENTUM CAMPHORÆ. *U. S., Lond., Ed., Dub. Camphor Liniment.*

"Take of Camphor *half an ounce;* Olive Oil *two fluidounces.* Dissolve the Camphor in the Oil." *U. S.*

The *London* and *Edinburgh Colleges* direct *an ounce* of camphor, and *four fluidounces* of olive oil; the *Dublin College*, *an avoirdupois ounce* of the former and *four fluidounces* of the latter.

This is employed as an anodyne embrocation in sprains, bruises, rheumatic or gouty affections of the joints, and other local pains. It is also supposed to have a discutient effect when rubbed upon glandular swellings.

Mr. Wm. B. Price, of Burlington, N. J., proposes a modification of this liniment, founded on the solvent power of chloroform over camphor, whereby the preparation is made stronger with camphor, and acquires also additional anodyne influence from the chloroform. The proposed liniment consists of *an ounce and a half* of camphor, *two fluidrachms* of chloroform, and *two fluidounces* of olive oil. It is useful in rheumatic and neuralgic pains. (*N. J. Med. Rep.*, ii. 217.)

Off. Prep. Linimentum Hydrargyri Compositum. W.

LINIMENTUM CAMPHORÆ COMPOSITUM. *Lond., Dub. Compound Camphor Liniment.*

"Take of Camphor *two ounces and a half;* Oil of Lavender *a fluidrachm;* Rectified Spirit *seventeen fluidounces;* Stronger Solution of Ammonia *three fluidounces.* Dissolve the Camphor and Oil in the Spirit; then add the Ammonia, and agitate together till they are mixed." *Lond.*

The *Dublin College* takes *five ounces* [avoirdupois] of camphor; *two fluidrachms* of oil of lavender, *a pint and a half* [Imp. meas.] of rectified spirit, and *half a pint* [Imp. meas.] of stronger solution of ammonia, and proceeds as above.

This preparation deserves a place rather among the spirits or tinctures than the liniments. It is used as a rubefacient and at the same time anodyne embrocation in local pains, particularly of a rheumatic character. W.

LINIMENTUM CANTHARIDIS. *U. S., Dub. Liniment of Spanish Flies.*

"Take of Spanish Flies, in powder, *an ounce;* Oil of Turpentine *half a pint.* Digest for three hours, in a close vessel, by means of a water-bath, and strain." *U. S.*

"Take of Spanish Flies, in fine powder, *three ounces* [avoirdupois]; Olive Oil *twelve fluidounces.* Digest the Flies in the Oil for three hours, in a steam or

water bath, and strain through flannel; express the residuum and strain the oil thus obtained; finally mix both products." *Dub.*

Oil of turpentine dissolves, especially with the aid of heat, the active principle of cantharides, and, when impregnated with it, acquires in addition to its own rubefacient properties those of a powerful epispastic. The U. S. liniment was introduced into notice by the late Dr. Joseph Hartshorne, of Philadelphia, who employed it with advantage as an external stimulant in the prostrate states of typhus fever. Caution, however, is necessary in its use, both to graduate its strength to the circumstances of the case, and not to apply it very extensively, lest it may produce troublesome, if not dangerous vesication. If too powerful, it may be diluted with olive or linseed oil. The Dublin preparation, in which olive oil is the solvent, exercises only the properties of the flies.

Off. Prep. Unguentum Cantharidis. W.

LINIMENTUM CROTONIS. *Dub. Croton Oil Liniment.*

"Take of Croton Oil *one fluidounce;* Oil of Turpentine *seven fluidounces.* Mix them with agitation." *Dub.*

This is a rubefacient and pustulating preparation, operating speedily in the former capacity through the oil of turpentine, and more slowly in the latter through the croton oil. From ten to thirty minims or more may be rubbed upon a limited surface, and repeated twice a day or oftener till an eruption is produced. W.

LINIMENTUM HYDRARGYRI. *Lond.* LINIMENTUM HYDRARGYRI COMPOSITUM. *Dub. Mercurial Liniment.*

"Take of Mercurial Ointment, Lard, each, *four ounces;* Camphor *an ounce;* Rectified Spirit *a fluidrachm;* Solution of Ammonia *four fluidounces.* Rub the Camphor first with the Spirit, then with the Lard and Ointment; lastly, add gradually the Solution of Ammonia, and mix the whole." *Lond.*

"Take of Ointment of Mercury *one ounce* [avoirdupois]; Camphor Liniment, Solution of Ammonia, of each, *one fluidounce.* Melt the Ointment in the Liniment, with a gentle heat, then add the Ammonia, and mix them with agitation." *Dub.*

This is a stimulating liniment, employed for the discussion of chronic glandular enlargements, swellings of the joints, and venereal tumours, and to promote the absorption of collections of fluid. It is said to be more apt to salivate than mercurial ointment. One drachm of it may be rubbed upon the affected part night and morning. W.

LINIMENTUM OPII. *Lond., Ed., Dub. Liniment of Opium. Anodyne Liniment.*

"Take of Castile Soap *six ounces;* Opium *an ounce and a half;* Camphor *three ounces;* Oil of Rosemary *six fluidrachms;* Rectified Spirit *two pints* [Imperial measure]. Macerate the Soap and Opium in the Spirit for three days; filter, add the Oil and Camphor, and agitate briskly." *Ed.*

The *Lond.* and *Dub. Colleges* mix their liniment of soap (*Tinctura Saponis Camphorata, U. S.*) with tincture of opium; the former, in the proportion of *six* measures of the liniment to *two* of the tincture, the latter, in equal measures.

This is commonly called *anodyne liniment*, and is employed as an anodyne and gently rubefacient embrocation in sprains, bruises, and rheumatic and gouty pains. It differs from *camphorated tincture of soap* only in containing opium, and is most conveniently prepared by extemporaneously mixing that tincture with laudanum, as directed by the London and Dublin Colleges. W.

LINIMENTUM SAPONIS CAMPHORATUM. *U. S. Camphorated Soap Liniment. Opodeldoc.*

"Take of Common Soap, sliced, *three ounces;* Camphor *an ounce;* Oil of Rosemary, Oil of Origanum, each, *a fluidrachm;* Alcohol *a pint.* Digest the

Soap with the Alcohol, by means of a sand-bath, till it is dissolved; then add the Camphor and Oils, and when they are dissolved, pour the liquor into broad-mouthed bottles. This liniment has, when cold, the consistence of a soft ointment." *U. S.*

This preparation differs from the common soap liniment (*Tinctura Saponis Camphorata, U. S.*) chiefly in being prepared with common white soap, made with animal fat, instead of Castile soap, which is made with olive oil. The former is peculiarly adapted to the purposes of this formula, in consequence of assuming, when its alcoholic solution cools, the consistence characteristic of the liniment. It is customary, after the solution of the soap has been effected, to pour the liquor into small wide-mouthed glass bottles, containing about four fluidounces, in which it concretes into a soft, translucent, uniform, yellowish-white mass. This liniment melts with the heat of the body, and therefore becomes liquid when rubbed on the skin. It is much used, under the name of *opodeldoc*, as an anodyne application in sprains, bruises, and rheumatic pains. W.

LINIMENTUM SIMPLEX. *Ed.* *Simple Liniment.*

"Take of Olive Oil *four parts;* White Wax *one part.* Dissolve the Wax in the Oil with a gentle heat, and agitate well as the fused mass cools and concretes." *Ed.*

This may be used for keeping the skin soft and smooth in cold weather.

Off. Prep. Unguentum Zinci. W.

LINIMENTUM TEREBINTHINÆ. *U. S., Lond., Dub.* LINIMENTUM TEREBINTHINATUM. *Ed.* *Liniment of Turpentine.*

"Take of Oil of Turpentine *half a pint;* Resin Cerate *a pound.* Add the Oil of Turpentine to the Cerate previously melted, and mix them." *U. S.*

"Take of Soft Soap *two ounces;* Camphor *an ounce;* Oil of Turpentine *sixteen fluidounces.* Shake them together until they are mixed." *Lond.*

"Take of Resinous Ointment *four ounces;* Oil of Turpentine *five fluidounces;* Camphor *half an ounce.* Melt the ointment, and gradually mix with it the Camphor and Oil, till a uniform liniment be obtained." *Ed.*

"Take of Oil of Turpentine *five fluidounces*; Ointment of Resin *eight ounces* [avoirdupois]. Melt the Ointment, then add the Oil of Turpentine gradually, and stir the mixture until a uniform liniment is obtained." *Dub.*

This preparation, made according to the U. S. and Dublin formulæ, is the liniment originally proposed by Dr. Kentish, and subsequently so highly lauded as a remedy in burns and scalds. It should be applied as soon after the occurrence of the accident as possible, and should be discontinued when the peculiar inflammation excited by the fire is removed. The best mode of application is to cover the burned or scalded surface with pledgets of patent lint saturated with the liniment. It should not be allowed to come in contact with the sound parts. This liniment may also be successfully applied in other cases of cutaneous inflammation requiring stimulation, as in certain conditions of erysipelas. The liniment of the London College is a stimulating mixture, applicable wherever a powerful rubefacient impression is desired. W.

MAGNESIA.

Preparations of Magnesia.

MAGNESIA. *U. S., Lond., Ed., Dub.* *Magnesia.*

"Take of Carbonate of Magnesia *any quantity.* Put it into an earthen vessel, and expose it to a red heat for two hours, or till the carbonic acid is wholly expelled." *U. S.*

"Take of Carbonate of Magnesia *a pound*. Burn it for two hours in a strong fire." *Lond.*

"Take *any convenient quantity* of Carbonate of Magnesia, expose it in a crucible to a full red heat for two hours, or till the powder, when suspended in water, presents no effervescence on the addition of muriatic acid. Preserve the product in well closed bottles." *Ed.*

"Take of Carbonate of Magnesia *any convenient quantity*. Introduce it into a clay crucible closed loosely by a lid, and let this be exposed to a low red heat as long as a little of the magnesia, taken from the central part of the crucible, when cooled, and dropped into dilute sulphuric acid, continues to give rise to effervescence. Let the product be preserved in well-closed bottles." *Dub.*

By exposure to a red heat, the water and carbonic acid of the carbonate of magnesia are expelled, and the earth is obtained pure. According to Dr. Black, the carbonate loses seven-twelfths of its weight by calcination. Brande says that the loss varies from 50 to 60 per cent., of which from 15 to 20 per cent. is water. About the close of the process the earth exhibits a luminous or phosphorescent appearance, which is said to be a good criterion of its freedom from carbonic acid. (*Duncan.*) A more certain indication, however, is the absence of effervescence when muriatic acid is added to a little of the magnesia, previously mixed with water. It is an error to suppose that a very intense heat is requisite in the calcination. The temperature of ignition is sufficient for the expulsion of the water and carbonic acid, and any increase serves only to render the magnesia harder, denser, less readily soluble in acids, and consequently less useful as a medicine. In order to ensure a pure product, care should be taken that the carbonate employed be free from lime. It should be rubbed to powder before being introduced into the pot or crucible; and, as in consequence of its levity it occupies a very large space, the plan has been proposed of moistening and compressing it in order to reduce its bulk. The magnesia may thus be obtained of greater density; but this is an equivocal recommendation; and the French pharmaceutical writers direct that the vessels employed should be sufficiently large to contain a considerable quantity of the carbonate, without the necessity of resorting to compression. The officinal direction, to keep the magnesia, after it has been prepared, in well stopped glass vessels, is founded on the fact that it absorbs carbonic acid and water from the air; but, as the absorption of the acid goes on very slowly, and that of water does not injure the preparation, the caution is often neglected in the shops. The great bulk of the earth renders its introduction into small bottles inconvenient. A four ounce bottle holds only about an ounce of the purest and finest magnesia. But its specific gravity is greatly increased by trituration; and four times the quantity may be thus got into the same space. (*Journ. of the Phil. Col. of Pharm.*, iii. 198.) The density of *Henry's Magnesia*, which is at least four times that of the earth prepared in the ordinary way, has been ascribed to this cause. It has also been attributed to the influence of intense heat employed in the calcination. The conjecture has even been advanced, that this magnesia, which has enjoyed so great a popularity in England and this country, is prepared by precipitating a solution of sulphate of magnesia by caustic potassa; as the earth afforded by this plan is comparatively dense. It is asserted that the magnesia, prepared from the carbonate procured by precipitating the sulphate of magnesia with carbonate of soda, is softer to the touch, and bears a closer resemblance to Henry's than that prepared from the ordinary carbonate. The fact is explained by the presence in common magnesia of a little sulphate of potassa, from which it is difficult entirely to free it in consequence of the sparing solubility of this salt, and of a portion of silica which originally existed in the carbonate of potassa employed to decompose the sulphate of magnesia, and of which the carbonate of soda is destitute. According to Mr. Richard Phillips, jun., if equivalent quantities of

crystallized sulphate of magnesia and crystallized carbonate of soda be boiled together in water, the mixture evaporated to dryness, the residual salts calcined, and the sulphate of soda dissolved out by water, the magnesia obtained will be dense. (*Am. Journ. of Pharm.*, xvi. 118, from the *Pharm. Journ.*) It is said that if the heat be kept low during calcination the resulting magnesia is light, if high, it is dense. By packing the carbonate closely in the crucible, or by moistening and then compressing it strongly in a cloth, before calcination, a heavy magnesia is obtained. The advantages of Henry's magnesia, independently of the convenience of its less bulk, are its greater softness, and more ready miscibility with water. Preparations similar to Henry's are made by T. J. Husband and by Charles Ellis, of Philadelphia, and sold under the names respectively of *Husband's* and of *Ellis's Magnesia.**

Properties, &c. Magnesia is a very light, white, inodorous powder, of a feeble alkaline taste. Its sp. gr. is commonly stated at 2·3. It was deemed infusible, till melted by means of the compound blowpipe of Dr. Hare. Water sprinkled upon it is absorbed to the extent of about 18 per cent., but with scarcely any increase of temperature. It is almost insoluble, requiring, according to Dr. Fyfe, 5142 parts of water at 60°, and 36,000 parts of boiling water for solution. Water thus impregnated has no effect on vegetable colours; but magnesia itself produces a brown stain by contact with moistened turmeric paper. Magnesia is a metallic oxide, consisting of one equivalent of magnesium 12, and one of oxygen 8=20. *Magnesium* is a white, very brilliant metal, resembling silver, malleable, fusible at a low temperature, and convertible into magnesia by the combined action of air and moisture. There is a hydrate of magnesia consisting of one equiv. of the earth and one of water. Magnesia forms with nitric and muriatic acids, salts which are soluble in alcohol, and very deliquescent. It is precipitated from its saline solutions by the pure alkalies in the state of a hydrate, and by the carbonates of potassa and soda as a carbonate; but it is not precipitated by the alkaline bicarbonates, nor by common carbonate of ammonia.

Magnesia is liable to contain, as impurities, carbonate of magnesia, lime, alumina, silica, and small quantities of the soluble salts employed or produced in the preparation of the carbonate from which it is procured. The presence of carbonate of magnesia is indicated by effervescence when the earth is dissolved

* The three kinds of heavy magnesia sold in our market have been examined by Prof. Procter, with the following results. All are heavier than common magnesia, more readily miscible with water, smoother upon the tongue, and of a less quickly developed taste; but they differ in these respects, Henry's standing first, Husband's second, and Ellis's last. But the two latter are much more readily acted on by acids than Henry's, differing in this respect little from each other. Both, moreover, though less readily miscible with water than Henry's, are longer retained in suspension, and Ellis's exceeds Husband's in this quality. In reference, therefore, to mere facility of administration and to taste, it appears that the imported magnesia has the advantage; but for forming liquid mixtures, and for rapidity of antacid action, the American are preferable. Husband's was found to contain 7 per cent. of combined water; the two others lost at a red heat only seven-tenths of one per cent. (See *Am. Journ. of Pharm.*, xxii. 383.)

Dr. Pereira found light magnesia, under the microscope, to exhibit the same forms observed in the light carbonate, namely, an amorphous portion of a flocculent or granular consistence, and another consisting of fragments of prismatic crystals; while the *heavy magnesia* was homogeneous, exhibiting no traces of crystals, and composed of minute granules more or less cohering into small soft balls or masses. (*Pharm. Journ. and Trans.*, viii. 235.)—*Note to the ninth edition.*

After this sheet had been prepared for the press, we received the number of the *Am. Journ. of Pharm.* for May, 1854, in which is an interesting experimental essay by Mr. T. H. Barr, on the preparation of heavy magnesia. The author, after trying various methods, obtained the best results either by precipitating a hot concentrated solution of sulphate of magnesia with a like solution of carbonate of soda, or by decomposing chloride of magnesium by heat. For more precise information the reader is referred to the paper itself, vol. xxvi. p. 193.—*Note to the tenth edition.*

in muriatic acid. Lime, which is a very frequent impurity, and imparts to the magnesia a more strongly alkaline and more disagreeable taste, is detected by oxalate of ammonia or bicarbonate of potassa. Neither of these salts disturbs a neutral solution of pure magnesia in a dilute acid; but if lime be present, both produce precipitates, the former of oxalate, the latter of carbonate of lime. As magnesia is completely dissolved by muriatic acid, silica and other impurities insoluble in that acid would be left behind. Alumina is indicated by the production of a precipitate, when ammonia is added in excess to a solution of fifty grains of magnesia in a fluidounce of muriatic acid. (*Christison's Dispensatory.*) If the magnesia contain a soluble sulphate or carbonate, from insufficient washing of the carbonate of magnesia, from which it was prepared, chloride of barium will reveal it by producing a precipitate with water digested on the magnesia.

Medical Properties and Uses. Magnesia is antacid and laxative; and is much employed, under the name of *calcined magnesia*, in dyspepsia, sick headache, gout, and other complaints attended with sour stomach and constipation. It is also a favourite remedy in the complaints of children, in which acidity of the primæ viæ is often a prominent symptom. Its antacid properties render it very useful in gravel attended with an excessive secretion of uric acid. Its advantages over carbonate of magnesia are that it may be given in a smaller dose, and does not occasion flatulence. The dose as a laxative is from thirty grains to a drachm; as an antacid merely, or antilithic, from ten to thirty grains twice a day. When it meets with no acid, it is apt to linger in the stomach or bowels, and may in that case be followed by lemonade. It should be administered in water or milk, and should be thoroughly triturated so as to render the mixture uniform. If mixed with less than 14 or 15 times its weight of water, and allowed to stand for a day or two, magnesia is apt to form with the liquid a more or less concrete mass, owing to the production of a hydrate of the earth, and the solidification of a portion of the water. This change does not take place, or at least takes place much less readily, when magnesia already saturated with moisture is employed instead of that freshly calcined. It has been conjectured that anhydrous magnesia might prove injurious in the stomach by solidifying its liquid contents; and the earth which has become saturated with moisture by exposure to a damp air is preferably recommended. (*Journ. de Pharm.*, 3*e sér.* iv. 360, and v. 475.) Freshly precipitated hydrate of magnesia will serve as an antidote to arsenious acid, though less efficient than hydrated sesquioxide of iron. Magnesia is used in the process for preparing veratria.

Off. Prep. Pilulæ Copaibæ; Pulvis Rhei Compositus; Trochisci Magnesiæ. W.

LIQUOR MAGNESIÆ CITRATIS. *U.S.* *Solution of Citrate of Magnesia.*

"Take of Carbonate of Magnesia *five drachms;* Citric Acid *seven drachms and a half;* Syrup of Citric Acid *two fluidounces:* Water *a sufficient quantity.* Dissolve the Citric Acid in four fluidounces of Water, and add to the solution four drachms of the Carbonate of Magnesia, previously rubbed with three fluidounces of Water. When the reaction has ceased, filter the solution into a strong glass bottle, of the capacity of twelve fluidounces, into which the Syrup of Citric Acid has been previously introduced. Rub the remaining Carbonate of Magnesia with two fluidounces of Water, and pour the mixture into the bottle, which is then to be tightly corked, and secured with twine. Lastly, shake the mixture occasionally until it becomes transparent." *U. S.*

This new officinal of the U. S. Pharmacopœia of 1850 is founded on a preparation proposed by M. Rogé Delabarre, and improved by M. Rabourdin, of Paris. It is an aqueous solution of citrate of magnesia, containing an excess of citric acid, impregnated with carbonic acid, and sweetened with syrup. The ex-

cess of citric acid taken, together with the citric acid in the syrup, amounts to about 14½ grains. Four-fifths of the carbonate of magnesia are dissolved in the citric acid, forming an acid citrate of magnesia, the acidity of which is increased by being filtered upon the syrup of citric acid, contained in the bottle. The filtration serves to separate any gritty impurities which may happen to be contained in the carbonate. The reserved fifth of the carbonate is now rubbed up with water, and added to the bottle, which is then tightly closed with a cork, secured by twine. This last addition of carbonate of magnesia generates a fresh portion of the citrate, with evolution of carbonic acid, which is prevented from escaping from the bottle by its immediate and firm closure. The magnesia, thus added, is not sufficient to neutralize the whole of the free citric acid; so that the preparation, when finished, is still an acid citrate of magnesia. If the portion of carbonate of magnesia used in completing the preparation should be impure, and not all soluble in the citric acid, it will give rise to a sediment in the solution. Any similar insoluble portion, depending upon impurity in the carbonate first dissolved, is removed by the filtration ordered. The dispensing apothecary will be able to judge of the quality of his carbonate of magnesia by the solution of it in the citric acid in the beginning of the process; for, if good, it will entirely dissolve, and filtration will not remove anything The total bulk of the liquid ingredients is eleven fluidounces; but the solution of the solids will increase the total volume to near twelve fluidounces, the capacity of the bottle directed.

Properties, &c. This solution is a transparent liquid, having an agreeable taste, like that of lemonade. Overlooking the slight excess of acid which it contains, the salt present in it may be considered to be the neutral or tribasic citrate, consisting of one eq. of citric acid and three of magnesia. In the recent solution this salt is wholly soluble, but in that which has been kept for some days it undergoes a molecular change, and precipitates as a white granular powder, rendering the solution unfit for medicinal use. This precipitate has been analyzed by Prof. Procter, who finds it to consist of one eq. of citric acid, three of magnesia, and fourteen of water. (*Am. Journ. of Pharm.*, July, 1851.) Various modes have been suggested of obviating the liability of this solution to precipitate upon being kept. Some have used a considerable excess of acid; and a solution made in this way will keep for a longer time. Although it is true that the officinal solution will form a deposit on being kept, yet it must be recollected that it was never intended to be kept. It is strictly an extemporaneous solution, to be made at the time it is ordered. The revisers of the U. S. Pharmacopœia so considered it, and, therefore, ordered a quantity to be made in the formula, equal to a full dose. The formula calls for filtration; and the solution of the second portion of carbonate of magnesia added requires at least half an hour to effect it. To avoid the loss of time thus occasioned, some pharmaceutists use magnesia instead of the carbonate, thus forming a solution which rarely requires filtering, and complete the preparation by adding forty grains of bicarbonate of potassa, instead of the reserved carbonate of magnesia, with the effect of forming a clear solution at once, and of introducing into it a small portion of citrate of potassa. These varations from the formula are not admissible when the U. S. solution is prescribed under its officinal name, or is clearly indicated as the preparation wanted.

Dorvault makes a solid citrate of magnesia which is perfectly and readily soluble, by melting on a sand-bath *one hundred parts* of crystallized citric acid in its water of crystallization, and thoroughly incorporating with it *twenty-nine parts* of calcined magnesia. A pasty mixture is thus formed, which soon hardens, and may be pulverized for use. Citrate of magnesia, thus prepared, is soluble in twice its weight of water. When in saturated solution it soon precipitates as a nearly insoluble hydrate; but when dissolved in eight or ten times its weight of water, it forms a permanent solution. See the report on the solid citrate, made

by E. Parrish and A. Smith, to the Phil. Coll. of Pharmacy (*Am. Journ. of Pharm.*, April, 1852, p. 113), and M. E. Robiquet's paper on lemonades of citrate of magnesia (*Journ. de Pharm.*, April, 1852, p. 295).

Medical Properties. This solution is a cooling cathartic, and operates mildly. It has come into extensive use in Philadelphia, and perhaps other cities in the Union, on account of the facility with which it may be taken. The dose as a full purge is the whole quantity directed in the formula, or twelve fluidounces; as a laxative, half that quantity or less. In relation to this solution, see a paper by Prof. Procter, in the *Am. Journ. of Pharm.* for July, 1851. B.

MELLITA.

Preparations of Honey.

Honey is used in pharmacy chiefly as the vehicle of more active medicines. It is said to have this advantage over syrup, that its preparations are less apt to become candied; but, as it contains principles which disagree with the stomach in many persons, and as its variable consistence prevents the same exact precision in regard to proportion as is attainable with a solution of pure sugar, it is at present little employed. The preparations in which honey and vinegar are combined are called *Oxymels.*

Medicated honeys are of a proper consistence, if, when a small quantity, allowed to cool upon a plate, is divided by the edge of a spoon, the portions do not readily coalesce. A more accurate criterion, however, is their specific gravity, which should be 1·319 (35° B.) at ordinary temperatures, and 1·261 (30° B.) at the boiling point of water. The specific gravity is most readily determined by means of the saccharometer. W.

MEL DESPUMATUM. *U.S.* Mel Depuratum. *Dub. Clarified Honey.*

"Take of Honey *any quantity.* Melt it by means of a water-bath, and then remove the scum." *U. S.*

The *Dublin College* prepares it by melting in a water-bath, and straining while hot through flannel.

Honey, by the heat of the water-bath, becomes so fluid that the wax and other lighter impurities which it contains rise to the surface, and may be skimmed off; while the heavier substances which may have been accidentally or fraudulently added, such as sand or other earth, sink to the bottom.

The following method of clarifying honey has been practised in France. Take of white honey 3000 parts; water 750 parts; carbonate of lime, powdered and washed, 96 parts. Mix them in a suitable vessel, and boil for three minutes, stirring constantly. Then add 96 parts of animal charcoal previously washed, heated to redness, powdered, and sifted, and boil for a few minutes. Lastly, add the whites of two eggs beat up with 500 parts of water, and bring the liquid to the boiling point. Withdraw the vessel from the fire, and, after the mixture has cooled for fifteen minutes, strain it through flannel, and repeat the straining till the liquid passes perfectly clear. Should it not have the proper consistence, it should be concentrated sufficiently by a quick boiling. The use of the carbonate of lime is to saturate any acid in the honey, which might favour the formation of glucose, and thus increase the tendency to granulation. The French Codex simply directs six pounds of white honey to be heated with three pounds of water, skimmed, concentrated to 30° B. while boiling hot, and then strained through flannel.

The following method of clarifying honey is recommended by André von Hirschberg. Boil twenty-five pounds of honey, to which half the quantity of

water has been added, with a pulp obtained by stirring three sheets of white blotting-paper with water, over a slow fire till the pulp is reduced to minute fibres. When the mixture cools, put it into a woollen filtering-bag, previously moistened, and allow the honey to pass. It comes away perfectly clear. The paper pulp may then be washed, and the dark wine-coloured liquid which passes, evaporated by a water-bath to the proper consistence. (*Pharm. Journ. and Trans.*, ix. 543, from *Arch. der Pharm.*)

Honey clarified with carbonate of lime and animal charcoal, as in the first process described, is as clear and colourless as syrup made with sugar, but still retains a peculiar flavour. It is less disposed to ferment than crude honey, and is said not to be so liable to produce griping pain when swallowed.

Off. Prep. Confectio Aromatica; Confectio Opii; Confectio Piperis Nigri; Confectio Rosæ; Confectio Scammonii; Confectio Sulphuris; Confectio Terebinthinæ; Mel Boracis; Mel Rosæ; Oxymel; Oxymel Scillæ; Pilulæ Ferri Carbonatis; Tinctura Opii Camphorata. W.

MEL BORACIS. *Lond., Ed., Dub. Honey of Borax.*

"Take of Borax, in powder, *a drachm;* Honey [Clarified Honey, *Dub.*] *an ounce.* Mix them." *Lond., Ed., Dub.*

This preparation might well be left to extemporaneous prescription. It is used in the thrush of infants, and aphthous ulcerations of the mouth. W.

MEL ROSÆ. *U. S., Lond., Ed. Honey of Roses.*

"Take of Red Roses, in coarse powder, *two ounces;* Clarified Honey *twenty fluidounces;* Boiling Water *twelve fluidounces.* Macerate the Roses in eight fluidounces of boiling Water for four hours, in a glass or earthen vessel; then, with strong pressure, remove as much as possible of the infusion, and set it aside. Macerate the residue in four fluidounces of the boiling Water for half an hour, and again express. Reserving four fluidounces of the first infusion, mix the remainder with the infusion last obtained, add the Honey, and by means of a water-bath evaporate to a pint. Lastly, add the reserved infusion, and strain." *U. S.*

The *London College* macerates *four ounces* of dried red roses in *sixteen fluidounces* of boiling distilled water for two hours; then gently expresses with the hand, and strains. The residue it macerates for a little while in *eight fluidounces* of boiling water, and pours off the liquor. To this it adds the half of the former infusion, and places the other half aside. Lastly, it adds the mixed liquors to the honey, and evaporates by a water-bath, so that upon the admixture of the liquor set aside, the proper consistence may be obtained. The *Edinburgh College*, operating upon the same quantity of roses and honey, infuses the petals for six hours in *two pints and a half* [Imperial measure] of boiling water, strains with expression, allows the impurities to subside, decants the clear liquor, adds the honey, and evaporates in the vapour-bath to the consistence of syrup, removing the scum which forms.

The object in reserving a portion of the first infusion, as in the U. S. and London processes, is to avoid the evaporation of the volatile oil in the concentration of the infusion, and thus to preserve the flavour as well as the astringency of the roses in the preparation. The honey of roses forms a pleasant addition to the gargles employed in inflammation and ulceration of the mouth and throat. W.

OXYMEL. *Lond., Dub. Oxymel.*

"Take of Acetic Acid *seven fluidounces;* Distilled Water *eight fluidounces;* Honey *five pounds.* Add the Acid to the Water, and mix them with the Honey previously heated." *Lond.*

"Take of Clarified Honey *one pound* [avoirdupois]; Acetic Acid of Commerce (sp. gr. 1·044) *three ounces* [avoird]. Mix the Acid with the Honey previously heated." *Dub.*

This mixture of honey and vinegar forms a pleasant addition to gargles, and is sometimes used as a vehicle of expectorant medicines, and to impart flavour to drinks in febrile complaints. W.

OXYMEL SCILLÆ. *U. S., Lond. Oxymel of Squill.*

"Take of Vinegar of Squill *two pints;* Clarified Honey *a pint and a half.* Mix them, and evaporate by means of a water-bath to the proper consistence. The specific gravity of the Oxymel of Squill should be 1·32." *U. S*

The *London College* takes *five pounds* of honey and *two pints and a half* [Imperial measure] of vinegar of squill, evaporates the vinegar with a slow fire to twelve fluidounces, and mixes it with the honey previously heated.

This preparation has the virtues of squill, but is in no respect superior to the syrup. Prepared according to the directions of the London College, it would be very liable to be injured by heat. It is chiefly used as an expectorant in chronic catarrh, humoral asthma, hooping-cough, and generally in those states of the pulmonary organs in which the bronchial tubes are loaded with a viscid mucus of difficult expectoration. The dose is from one to two fluidrachms. In large doses it is emetic, and as such may sometimes be given with advantage in infantile croup and catarrh. W.

MISTURÆ.

Mixtures.

This term should be restricted, in the language of pharmacy, to those preparations in which insoluble substances, whether solid or liquid, are suspended in watery fluids, by the intervention of gum Arabic, sugar, the yolk of eggs, or other viscid matter. When the suspended substance is of an oleaginous nature, the mixture is sometimes called an *emulsion.* The object of these preparations is usually to facilitate the administration, to conceal the taste, or to obviate the nauseating effects of unpleasant medicines; and their perfection depends upon the intimacy with which the ingredients are blended. Some skill and care are requisite for the production of a uniform and perfect mixture. As a general rule, the body to be suspended should be thoroughly mixed by trituration with the substance intended to act as the intermedium, before the watery vehicle is added. In the case of the liquid balsams and oils, if gum Arabic be employed as the intermedium, it should be previously brought to the state of mucilage of the consistence directed in the U. S. Pharmacopœia. The white of eggs has been frequently ordered by physicians as the suspending substance; but it is inferior for this purpose to the yolk, or to gum Arabic. When the white is used it should be well beaten, and incorporated with the oleaginous or balsamic substances before the water is added.* Mixtures are generally the objects of extemporaneous prescription; but a few have been deemed of sufficient importance to merit a place in the Pharmacopœias. They should be prepared only when wanted for use. W.

MISTURA ACACIÆ. *Ed. Gum Arabic Mixture.*

"Take of Mucilage [of gum Arabic] *three fluidounces;* Sweet Almonds *one*

* For some good practical observations upon the preparation of mixtures, the reader is referred to a communication published in the *Journal of the Philadelphia College of Pharmacy,* vol. iv. p. 11, by W. Hodgson, Jun. The proportion of gum and water necessary to make a good emulsion with the fixed oils varies with the oil. Thus, while castor oil requires only two drachms of the gum and three drachms of water to the ounce, most other fixed oils require half their weight of gum, and a weight of water equal to half that of the oil and gum united. These quantities being well rubbed together, any desirable amount of water may afterwards be gradually added, and will readily incorporate with the other ingredients. (Overbeck, *Pharm. Cent. Blatt,* A. D. 1851, p. 95.)

ounce and two drachms; Pure Sugar *five drachms;* Water *two pints* [Imperial measure]. Steep the Almonds in hot water and peel them; beat them to a smooth pulp in an earthenware or marble mortar, first with the Sugar, and then with the Mucilage; add the water gradually, stirring constantly, then strain through linen or calico." *Ed.*

This mixture is used as a demulcent in the dose of one or two fluidounces, or as a vehicle for various medicines in inflammatory affections of the bronchial, alimentary, and urinary mucous membranes. W.

MISTURA ALTHÆÆ. *Ed. Marsh Mallow Mixture.*

"Take of Althæa-root, dried, *four ounces;* Raisins, freed of the seeds, *two ounces;* boiling Water *five pints* [Imperial measure]. Boil down to three pints; strain through linen or calico, and when the sediment has subsided, pour off the clear liquor for use." *Ed.*

This should have been placed by the Edinburgh Pharmacopœia among the decoctions. It is essentially a mucilage flavoured with raisins, and may be used advantageously as a drink, in all cases in which demulcents are indicated. W.

MISTURA AMMONIACI. *U. S., Lond., Dub. Ammoniac Mixture.*

"Take of Ammoniac *two drachms;* Water *half a pint.* Rub the Ammoniac with the Water gradually added, until they are thoroughly mixed." *U. S.*

The *London College* takes *five drachms* of prepared ammoniac, and *a pint* [Imperial measure] of water; the *Dublin, two drachms* [Dublin weight] of ammoniac and *eight fluidounces* of water; both proceed as above, the Dublin directing that the mixture should be strained through muslin.

In this mixture the insoluble part of the ammoniac is suspended by means of the gum, imparting a milky appearance to the preparation, which, from this circumstance, was formerly called *lac ammoniaci* or *milk of ammoniac.* The greater portion of the resin subsides upon standing. The mixture is slightly curdled by acids. The dose is from one to two tablespoonfuls. W.

MISTURA AMYGDALÆ. *U. S., Lond., Dub.* MISTURA AMYGDALARUM. *Ed. Almond Mixture. Almond Emulsion.*

"Take of Sweet Almonds *half an ounce;* Gum Arabic, in powder, *half a drachm;* Sugar *two drachms;* Distilled Water *eight fluidounces.* Macerate the Almonds in water, and, having removed their external coat, beat them with the Gum Arabic and Sugar, in a marble mortar, till they are thoroughly mixed; then rub the mixture with the Distilled Water gradually added, and strain." *U. S.*

"Take of Almond Confection *two ounces and a half;* Distilled Water *a pint* [Imperial measure]. To the Confection, while rubbing it, gradually add the Water till they are mixed; then strain through linen." *Lond.*

"Take of Conserve of Almonds *two ounces;* Water *two pints* [Imp. measure]. Add the Water gradually to the Confection, triturating constantly; and then strain through linen or calico. Or,

"Take of Sweet Almonds *one ounce and two drachms;* Pure Sugar *five drachms;* Mucilage *half a fluidounce;* Water *two pints* [Imp. measure]. Steep the Almonds in hot water and peel them; and proceed as for the Mistura Acaciæ." *Ed.*

"Take of Sweet Almonds *five drachms* [Dub. weight]; Refined Sugar *two drachms* [Dub. weight]; Gum Arabic, in powder, *one drachm* [Dub. weight]; Distilled Water *eight* [*fluid*]*ounces.* Steep the Almonds in hot water for five minutes, and, having removed their external coat, beat them with the Sugar and Gum, in a mortar, into a coarse powder; add the Water gradually, and triturate so as to form a uniform mixture. Finally, strain through muslin." *Dub.*

Of the above modes of preparing the almond emulsion, we prefer those in which the mixture is made directly from the almonds, and not from the confection. This very speedily spoils if kept; and it would be a very unnecessary

complication of the process to prepare it each time that the emulsion might be wanted. The London and first Edinburgh processes are, therefore, objectionable. In the second process of the Edinburgh College, mucilage is employed instead of powdered gum Arabic, but the latter is preferable, as less likely to have undergone change. The preparations, however, of the different Pharmacopœias are essentially the same. The gum Arabic in these formulæ is introduced not so much for its demulcent properties as to assist in the suspension of the insoluble ingredients of the almonds. In the Mistura Acaciæ, described at page 1075, it is the prominent ingredient. The same formula will answer for the preparation of an *emulsion of bitter almonds*, which may be preferred to the present when a slight influence of hydrocyanic acid is desired.

The oleaginous matter of the almonds is suspended in the water by means of their albumen, gum, and sugar, forming a milky emulsion. When the almonds themselves are employed, as in the U. S. process, care should be taken to reduce them to the consistence of a paste previously to the addition of the water; and with each successive portion of fluid a uniform mixture should be formed before another portion is added. Common water, when not very impure, may be properly substituted for the distilled. Great care should be taken to select the almonds perfectly free from rancidity. The mixture is not permanent. Upon standing, the oil rises like thick cream to the surface, and the separation is effected more quickly by heat, alcohol, and the acids, which coagulate the albumen. It has a close analogy to milk in chemical relations as well as in appearance. The preparation, in warm weather, soon becomes sour, and unfit for use.

The almond mixture has a bland taste, and may be used as an agreeable, nutritive demulcent in catarrhal and dysenteric affections, and irritation of the urinary passages. To be of service it must be freely employed. From two to eight fluidounces may be taken at once. It is occasionally employed as the vehicle of less agreeable medicines; but should not be used in connexion with any considerable quantity of tinctures, acidulous salts, or other substances containing an excess of acid. W.

MISTURA ASSAFŒTIDÆ. *U. S.* *Assafetida Mixture.*

"Take of Assafetida *two drachms;* Water *half a pint.* Rub the Assafetida with the Water gradually added, until they are thoroughly mixed." *U. S.*

This mixture, from its whiteness and opacity, is frequently called *lac assafœtidæ*, or *milk of assafetida.* It is, as a general rule, the best form for the administration of this antispasmodic, being less stimulant than the tincture, and more prompt in its action than the pill. Its excessively disagreeable smell and taste are, however, objections, which induce a frequent preference of the last-mentioned preparation. It is very often employed as an enema. The dose is from one to two tablespoonfuls frequently repeated. From two to four fluidounces may be given by the rectum.* W.

MISTURA CAMPHORÆ CUM MAGNESIÂ. *Ed.* *Mixture of Camphor with Magnesia.*

"Take of Camphor *ten grains;* Carbonate of Magnesia *twenty-five grains;* Water *six fluidounces.* Triturate the Camphor and Carbonate of Magnesia together, adding the Water gradually." *Ed.*

* *Syrup of Assafetida.* Such a preparation has been proposed by Mr. Richard Petty. He has found the following formula to answer the purpose best. Take of assafetida ℥j, boiling water Oj, sugar ℔ij. Rub the assafetida with a part of the water so as to make a uniform paste, then gradually add the remainder of the water, strain, and add the sugar, heating moderately till it is dissolved. This has a less disagreeable taste than the mixture, and keeps much better, remaining several months without change, while the latter is often altered in a short time. The dose is the same as that of the mixture. (*Am. Journ. of Pharm.*, xxiv. 319.)—*Note to the tenth edition.*

This differs from the *Aqua Camphoræ* of the U.S. Pharmacopœia, in which, though the camphor is dissolved by the intervention of carbonate of magnesia, the latter is afterwards separated by filtration. In the above mixture the carbonate of magnesia is retained; and an anodyne, antacid, and laxative draught is formed, which, though it may sometimes be given with advantage, hardly deserves a place among the officinal preparations.

Camphor, with a view to its full effects upon the system, is frequently given in the form of liquid mixture, being suspended in water by various intermedia, as gum Arabic, the yolk of eggs, &c. The addition of resinous substances, as myrrh for example, softens the camphor, and enables it to be more readily retained in suspension. Chloroform, by its solvent power over camphor, answers this purpose admirably. (See *Camphora*, p. 164.) Before mixing camphor with the suspending substance, it should be powdered with the aid of a few drops of alcohol. A good plan also is to rub it first with half its weight of olive oil, then with sugar and gum Arabic, and lastly, with water gradually added. W.

MISTURA CREASOTI. *Ed.* *Creasote Mixture.*

"Take of Creasote and Acetic Acid, of each, *sixteen minims;* Compound Spirit of Juniper and Syrup, of each, *one fluidounce;* Water *fourteen fluidounces.* Mix the Creasote with the Acid, then gradually the Water, and lastly the Syrup and Spirit." *Ed.*

The dose of this mixture is a fluidounce, containing a minim of creasote.

MISTURA CRETÆ. *U.S., Lond., Ed., Dub.* *Chalk Mixture.*

"Take of Prepared Chalk *half an ounce;* Sugar [refined], Gum Arabic, in powder, each, *two drachms;* Cinnamon Water, Water, each, *four fluidounces.* Rub them together till they are thoroughly mixed." *U. S.*

The *London College* orders *half an ounce* of prepared chalk, *three drachms* of sugar, *a fluidounce and a half* of mixture (mucilage) of gum Arabic, and *eighteen fluidounces* of cinnamon water. The *Edinburgh College* takes *ten drachms* of prepared chalk, *five drachms* of pure sugar, *three fluidounces* of mucilage of gum Arabic, *two ounces* (fluidounces) of spirit of cinnamon, and *two Imperial pints* of water; rubs the chalk, mucilage, and sugar together, and then adds gradually the water and spirit of cinnamon. The *Dublin College* rubs *two drachms* [Dub. weight] of prepared chalk with *seven fluidounces* of cinnamon water, then adds *half a fluidounce*, each, of mucilage of gum Arabic and simple syrup, and mixes.

This mixture is a convenient form for administering chalk, and is much employed in looseness of the bowels accompanied with acidity. Laudanum and kino or catechu are very often added to increase its astringency. The dose is a tablespoonful frequently repeated. W.

MISTURA FERRI AROMATICA. *Dub.* *Aromatic Mixture of Iron.*

"Take of Peruvian Bark (crown or pale), in powder, *one ounce;* Calumba Root, in coarse powder, *three drachms;* Cloves, bruised, *two drachms;* Filings of Iron, separated by a magnet, *half an ounce.* Digest for three days in a covered vessel, with occasional agitation, with as much Peppermint Water as will give *twelve* [*fluid*]*ounces* of a filtered product, and then add, of Compound Tincture of Cardamom *three* [*fluid*] *ounces;* Tincture of Orange Peel *three* [*fluid*] *drachms.* This mixture should be kept in a well stopped bottle." *Dub.* The weights used here are the avoirdupois, with the Dublin divisions.

This is an aromatic infusion of Peruvian bark and columbo, and has not the slightest claim to the title given it in the Pharmacopœia; as it contains but a very small proportion of iron, and that in a state of solution, not of mixture. In consequence of the action of some of the vegetable principles upon the filings,

enough of the metal is taken up to impart a greenish-black colour to the liquor; but the quantity is not appreciable, as the filings seem to be scarcely diminished by the process. The preparation may be given as a tonic in the dose of one or two fluidounces. W.

MISTURA FERRI COMPOSITA. *U.S., Lond., Ed., Dub. Compound Mixture of Iron.*

"Take of Myrrh *a drachm;* Carbonate of Potassa *twenty-five grains;* Sulphate of Iron, in powder, *a scruple;* Spirit of Lavender *half a fluidounce;* Sugar [refined] *a drachm;* Rose Water *seven fluidounces and a half.* Rub the Myrrh with the Rose Water gradually added; then mix with these the Spirit of Lavender, Sugar, and Carbonate of Potassa, and, lastly, the Sulphate of Iron. Pour the mixture immediately into a glass bottle, which is to be well stopped." *U. S.*

"Take of Myrrh, in powder, *two drachms;* Carbonate of Potassa *a drachm;* Rose Water *eighteen fluidounces* [Imperial measure]; Sulphate of Iron, in powder, *two scruples and a half;* Spirit of Nutmeg *a fluidounce;* Sugar *two drachms.* Rub the Myrrh with the Spirit and Carbonate; and to these, while rubbing, add first the Rose Water with the Sugar, and then the Sulphate. Put the Mixture immediately into a glass vessel, and stop it." *Lond.*

The *Edinburgh* process differs from the London only in using the myrrh bruised, and the sulphate of iron in coarse powder. The *Dublin College* takes *a drachm* of myrrh, *half a drachm* of pure carbonate of potassa, *a fluidrachm* of essence of nutmeg, *eight fluidounces* of rose water, *a drachm* of refined sugar, and *half a drachm* of sulphate of iron, *using the Dublin weights;* rubs the myrrh, carbonate, and essence with seven fluidounces of the rose water; then adds the sulphate dissolved in the remaining fluidounce of rose water, and puts the mixture into a bottle, to be tightly corked.

This is very nearly the same with the celebrated tonic or antihectic myrrh mixture of Dr. Griffith. The sulphate of iron is decomposed by the carbonate of potassa, with the production of sulphate of potassa and carbonate of protoxide of iron; while the excess of the alkaline carbonate forms a saponaceous compound with the myrrh. The mixture is at first of a greenish colour, which it loses upon exposure to the air, in consequence of the conversion of the protoxide of iron of the carbonate into the red or sesquioxide. It may, however, be kept for some time without change, if the vessel in which it is contained be well closed; but the best plan is to prepare it only when it is wanted for use. The sugar contained in it probably contributes somewhat to retard the further oxidation of the protoxide of iron, and if considerably increased in amount would act still more efficiently. The finest pieces of myrrh in lump should be selected, and rubbed down for the occasion with a little of the rose water; as the powdered myrrh of the shops is often impure, and does not make a good mixture.

This mixture is a good tonic in debility of the digestive organs, especially when attended with derangement of the menstrual function. Hence it is used with advantage in chlorosis and hysterical affections. It has been also much employed in the hectic fever of phthisis and chronic catarrh. It is contraindicated by the existence of inflammation of the gastric mucous membrane. The dose is one or two fluidounces two or three times a day. W.

MISTURA GENTIANÆ COMPOSITA. *Lond. Compound Mixture of Gentian.*

"Take of Compound Infusion of Gentian *twelve fluidounces;* Compound Infusion of Senna *six fluidounces;* Compound Tincture of Cardamom *two fluidounces.* Mix them." *Lond.*

A tonic and cathartic preparation adapted to dyspepsia and constipation. The dose is one or two fluidounces. W.

MISTURA GLYCYRRHIZÆ COMPOSITA. *U. S.* *Compound Mixture of Liquorice. Brown Mixture.*

"Take of Liquorice [extract], in powder, Gum Arabic, in powder, Sugar, each, *half an ounce;* Camphorated Tincture of Opium *two fluidounces;* Antimonial Wine *a fluidounce;* Spirit of Nitric Ether *half a fluidounce;* Water *twelve fluidounces.* Rub the Liquorice, Gum Arabic, and Sugar with the Water gradually poured upon them; then add the other ingredients, and mix." *U. S.*

This is an exceedingly popular cough mixture, which was made officinal in the U. S. Pharmacopœia of 1850. The spirit of nitric ether is probably useful by somewhat retarding decomposition. The preparation is applicable to the advanced stages of catarrhal affections, after expectoration has become established. The dose is a tablespoonful for an adult; a teaspoonful for a child two years old. It should be well shaken when administered. W.

MISTURA GUAIACI. *Lond., Ed.* *Guaiac Mixture.*

"Take of Guaiac, in powder, *three drachms;* Sugar *half an ounce;* Gum Arabic, in powder, *two drachms;* Cinnamon Water *a pint* [Imperial measure]. Rub the Sugar with the Guaiac and Gum Arabic, and to these, while rubbing, add gradually the Cinnamon Water." *Lond.*

The *Edinburgh* process differs only in using *half a fluidounce* of mucilage, instead of the powdered gum, and *half a fluidounce* less of cinnamon water.

For the changes of colour which the guaiac in this mixture undergoes, and produces in other substances, see *Guaiaci Resina*, p. 377. From one to three tablespoonfuls may be given for a dose, and repeated two or three times a day, or more frequently. W.

MISTURA SCAMMONII. *Ed.* *Scammony Mixture.*

"Take of Resin of Scammony *seven grains;* unskimmed Milk *three fluidounces.* Triturate the Resin with a little of the Milk, and gradually with the rest of it till a uniform emulsion is formed." *Ed.*

This Edinburgh officinal is an imitation of a mixture recommended by Planche. The resin of scammony mixes admirably with the vehicle, and forms an emulsion scarcely distinguishable in appearance or taste from rich milk. Of course, it should be prepared only when wanted for immediate use. The whole is to be taken for a dose. W.

MISTURA SPIRITŪS VINI GALLICI. *Lond.* *Brandy Mixture.*

"Take of Brandy, Cinnamon Water, each *four fluidounces;* the yolks of *two* Eggs; Sugar [refined] *half an ounce;* Oil of Cinnamon *two minims.* Mix them." *Lond.*

A stimulant and nutritive draught, applicable to the sinking stage of low forms of fever, but scarcely entitled to a place in the Pharmacopœia. W.

MORPHIA.

Preparations of Morphia.

MORPHIA. *U. S., Dub.* *Morphia.*

"Take of Opium, sliced, *a pound;* Solution of Ammonia *six fluidounces;* Distilled Water, Alcohol, Animal Charcoal, each, *a sufficient quantity.* Macerate the Opium with four pints of Distilled Water for twenty-four hours, and, having worked it with the hand, digest for twenty-four hours, and strain. In like manner, macerate the residue twice successively with the same quantity of Distilled Water, and strain. Mix the infusions, evaporate to six pints, and filter; then add first five pints of Alcohol, and afterwards three fluidounces of the Solution

of Ammonia, previously mixed with half a pint of Alcohol. After twenty-four hours, pour in the remainder of the Solution of Ammonia, mixed, as before, with half a pint of Alcohol; and set the liquor aside for twenty-four hours, that crystals may form. To purify these, boil them with two pints of Alcohol till they are dissolved, filter the solution, while hot, through Animal Charcoal, and set it aside to crystallize." *U. S.*

"Take of Turkey Opium, cut into thin slices, *one pound* [avoirdupois]; Distilled Water *six pints* [Imperial measure]; Chloride of Calcium *six drachms* [Dub. weight]; Prepared Animal Charcoal *as much as is sufficient.* Macerate the Opium for twenty-four hours with a quart [two pints, Imp. meas.] of the Water, and decant. Macerate the residuum for twelve hours with a second quart of the Water, decant, and repeat this process with the rest of the water, subjecting the insoluble residuum to strong expression. Let the decanted solutions and expressed liquor be evaporated by a steam or water heat to the bulk of one pint, and then passed through a calico filter. Pour in now the chloride of calcium, first dissolved in four [fluid]ounces of distilled water, and then proceed with the evaporation until the solution is so far concentrated, that upon cooling nearly the whole of it becomes solid. Let this solid matter be enveloped in a couple of folds of strong calico, and subjected to powerful pressure, the dark liquid which exudes being reserved for subsequent use. The squeezed cake is now to be acted on with about half a pint of boiling water, and the whole being thrown upon a paper filter, the precipitate must be well washed. The filtered solution having been evaporated as before, cooled and solidified, the residue is to be again subjected to expression. If the product be not quite white, this process should be repeated a third time, the liquid forced out during expression being always preserved. Let the squeezed cake be dissolved in six [fluid]ounces of boiling water, and, if necessary, cleared by filtration through Prepared Animal Charcoal, the portion of it soaked by the filter being carefully washed out of it; and to the solution thus obtained let Water of Ammonia be added, in slight excess, and let the crystalline precipitate which forms when the liquor has cooled be collected on a paper filter, and washed with cold distilled water until the washings cease to give a precipitate upon being dropped into an acid solution of nitrate of silver. Lastly, let the filter be transferred to a porous brick, in order that the Morphia it contains may become dry.

"The liquids separated by expression from the Muriate of Morphia, in the preceding process, having been diluted with water, so as to occupy the bulk of four [fluid]ounces, and then supersaturated slightly with Ammonia, let the precipitate which forms be collected, after the lapse of six hours, on a filter, and washed with a little cold water. This, if redissolved in dilute muriatic acid, boiled with a little animal charcoal, and filtered, will, upon cooling, afford a crystalline deposit, from which, when pressed, dissolved in water, and supersaturated with ammonia, an additional quantity of morphia will be procured." *Dub.*

These processes will be better understood by a previous acquaintance with the properties and chemical relations of the substance in question.

Morphia crystallizes from alcohol in the form of small, colourless, shining crystals. It is inodorous and bitter. Exposed to a moderate heat, it loses its water of crystallization and the crystalline form, becoming white and opaque. At a higher temperature it melts, forming a yellowish liquid, which becomes white and crystalline upon cooling. Heated in the open air it burns with a bright flame, and at a red heat is wholly dissipated. It is insoluble or nearly so in cold water, soluble in rather less than 100 parts of water at 212°, slightly soluble in cold alcohol, and freely so in boiling alcohol, which deposits it upon cooling. It is dissolved also by the fixed and volatile oils, but very slightly if at all by ether. Its solution restores the blue colour of litmus paper reddened

by acids, and turns the yellow of turmeric to brown. With the acids it forms salts, which are generally soluble, and are decomposed by the alkalies. The solutions of potassa and soda are also capable of dissolving morphia, which is precipitated slowly on exposure to the air, in consequence of the absorption of carbonic acid. Solution of ammonia has to a certain extent the same solvent power; and hence the necessity, in precipitating morphia by this alkali, not to employ it in great excess. Morphia and its salts, by the contact of nitric acid, assume a blood-red colour, which ultimately changes to yellow. When added to a solution of iodic acid, or an acidulous iodate, they redden the liquid and set iodine free. (*Serullas.*) They assume a fine blue colour with the sesquichloride of iron, and the salts of the sesquioxide; at least this is true of morphia, its acetate, and oxalate; and the same effect will be produced by the other salts, if previously decomposed by an alkali. Water, acids, and alkalies, added in large quantity to the blue compound formed, destroy its colour. According to Pelletier, however, there occasionally exists in opium a principle called by him pseudomorphia, which becomes red under the action of nitric acid, and changes the salts of sesquioxide of iron blue, and yet is destitute of poisonous properties; so that the occurrence of these phenomena, in any medico-legal case, cannot be considered as certain evidence of the presence of morphia. (See *Am. Journ. of Pharm.*, viii. 77.) The terchloride of gold precipitates morphia first yellow, then bluish, and lastly violet. (*Larocque* and *Thibierge.*) Morphia is precipitated from its solutions by potassa or soda, and redissolved by an excess of the alkali. Infusions of galls and other vegetable substances containing tannic acid precipitate morphia in the state of a tannate, which is soluble in acetic acid; but, according to Dublanc, the alkali is not precipitated by pure gallic acid. If ammonia be added to a mixture of the solutions of chlorine and morphia, a dark-brown colour is produced, which is destroyed by a further addition of chlorine. The proportion of the ingredients of morphia is somewhat differently given by different writers. According to the most recent authorities, anhydrous morphia consists of one eq. of nitrogen 14, thirty-five of carbon 210, twenty of hydrogen 20, and six of oxygen 48=292, to which in the crystals are added two eqs. of water 18, or about 5·8 per cent.

Various processes for preparing morphia have been employed. In most of them the morphia is extracted from opium by maceration with water either pure or acidulated, is then precipitated by ammonia, and afterwards purified by the agency of alcohol, or by repeated solution in a dilute acid and precipitation.

Sertürner, the discoverer of morphia, made an infusion of opium in distilled water, precipitated the morphia by ammonia in excess, dissolved the precipitate in dilute sulphuric acid, precipitated anew by ammonia, and purified by solution in boiling alcohol, and crystallization.

The process of the French Codex is a modification of that of Sertürner. It is as follows. "Take of opium 1000 parts, solution of ammonia a sufficient quantity. Exhaust the opium, by means of cold water, of all its parts soluble in that menstruum. For that purpose, it is sufficient to treat the opium, four times consecutively, with ten parts of water to one of the drug, provided care be taken to macerate the opium for some hours, and to work it with the hands. Filter the liquors, and evaporate them to a quarter of their volume. Then add sufficient ammonia to render the liquor very sensibly alkaline. Boil for some minutes, always maintaining a slight excess of ammonia. Upon cooling, the morphia, impure and much coloured, will be precipitated in granular crystals, which are to be washed with cold water. Reduce this coloured morphia to powder, macerate it for twelve hours in alcohol of 24° Cartier (sp. gr. about 0·900); then decant the alcoholic liquid; dissolve the residuary morphia, already in great measure deprived of colour by the cold alcohol, in boiling alcohol of 33°

Cartier (sp. gr. about 0·850); add to the solution a little animal charcoal, and filter. Upon cooling, the morphia crystallizes in colourless needles. In this state the morphia always retains some narcotina, to free it from which, boil it with sulphuric ether in a matrass with a long neck surmounted by a refrigerator."

The process of the U. S. Pharmacopœia is an improvement upon the above, and is essentially the same with that of Dr. Edward Staples, published in the *Journal of the Philadelphia College of Pharmacy* (i. 15). Without repeating a description of the process, we shall make such remarks upon its several steps, as appear to us likely to be of practical advantage. The employment of water as the solvent is justified by the almost universal practice. It is true that dilute acetic acid has sometimes been employed, and Vogel states that the product thus obtained is much greater than when water alone is used. But when the opium is properly comminuted, either by being reduced to a coarse powder when dry, or by being finely sliced, in its ordinary state, water alone will be found sufficiently to extract the morphia, by a protracted maceration or digestion in successive portions of water, assisted by kneading, as directed in the Pharmacopœia. The acids have this disadvantage, that they dissolve more of the narcotina than pure water, and thus render the ultimate product more impure; for the narcotina which is originally taken up continues associated with the morphia in all the subsequent steps of the process. It has been proposed to expose the opium to fermentation with water and yeast, in order to facilitate the extraction of the morphia. By this plan M. Blondeau succeeded in procuring more of the alkaline principle than he could obtain by the ordinary mode; and his results were confirmed by the experiments of MM. Robiquet and Guibourt. According to these latter chemists, no alcohol is produced during the fermentation, which appears to act merely by disengaging the morphia from the combinations in which it naturally exists, and which tend to counteract the solvent power of the menstruum. Alcohol was proposed as the solvent by M. Guillermond, but is liable to the objection that it dissolves also the resin, a portion of which is afterwards precipitated with the morphia and embarrasses the process. Much of the resin, however, may be separated by distilling most of the alcohol from the tincture, and then adding water. The resin is precipitated, and the liquor may now be treated in the same manner as the aqueous infusion.* On the whole, however, the officinal mode of extraction will probably be found most satisfactory; and Mohr states that opium thus exhausted yields no more morphia even to muriatic acid; but he recommends that each maceration should be followed by strong expression. The infusion of opium having been prepared, the next object is to decompose the meconate or other salt of morphia contained in it. For this purpose solution of ammonia is added, which seizes the acid, and precipitates the organic alkali; but much colouring matter is thrown down along with the latter, occasioning some trouble to separate it, unless measures are taken to obviate this effect. The object is gained by mixing the infusion with alcohol, previously to the addition of the ammonia, and by employing the

* By a modification of the process of Guillermond, MM. Desmedt have succeeded in extracting all the morphia from opium, perfectly free from narcotina. Of crude opium 60 parts were treated with 240 of alcohol at 71° centigrade (160° F.), and expressed when cold; the residue was then treated in the same manner with 160 parts of alcohol; the liquor was introduced into a bottle well stopped; next day a copious crystallization of narcotina appeared, without the least morphia; the liquid was decanted, and, on the addition of 4 parts of ammonia, furnished a considerable quantity of morphia, free from narcotina. To the mother liquor a little distilled water was added, and the mixture was kept at the temperature of 24° C. In two days an additional quantity of the crystals of morphia was obtained equally free from narcotina. The opium was completely exhausted, and the 60 parts employed furnished 5 parts of morphia. (*Annuaire de Thérap.*, 1852, p. 31.)—*Note to the tenth edition.*

solution of ammonia itself in connexion with alcohol, as directed in the Pharmacopœia. This is the peculiarity and chief merit of the process of Dr. Staples. By the presence of the alcohol in all parts of the liquor, the colouring matter is dissolved as soon as it is separated by the ammonia, and the morphia is thus precipitated in a much purer state. The advantage of adding the ammonia in separate portions is, that the morphia, being thus more slowly disengaged, can be more completely deprived of its impurities by the alcohol of the mixture, than if the whole were liberated at once. It is necessary to be careful that the ammonia be not in great excess; as it has the property, under these circumstances, of dissolving the morphia in some degree, and will therefore lessen the product, while waste is incurred by its own unnecessary consumption. Very little more should be added than is sufficient to saturate the acid present. The solution of ammonia of the shops is often much below the officinal standard, and this should always be attended to in the process. Alcohol is mixed with the ammonia before it is added, in order that every particle of the separated morphia may come in contact with the particles of this fluid, and thus have the opportunity of being deprived of colouring matter. The crystals of morphia obtained by this first operation have a light-yellowish colour, and are much purer than when no alcohol is added to the infusion before the precipitation by ammonia. According to Dr. Staples, opium yields from 10 to 12½ per cent. of these crystals. Their purification by solution in boiling alcohol, is the concluding step of the operation. The liquid, on cooling, deposits the morphia in a crystalline state and nearly free from colour. As cold alcohol retains a portion of the morphia in solution, it should not be employed too largely. Alcohol somewhat reduced by water, is preferable to the highly rectified spirit; as it is less capable of holding the morphia in solution when cold. It is sufficiently strong for the purpose at 25° Baumé (sp. gr. 0·9032). The impure morphia remaining in the alcohol may be obtained by distilling off the latter, and when sufficiently accumulated may be purified by a separate operation. The crystals of morphia may also be purified by solution in dilute sulphuric acid, digestion with animal charcoal deprived of earthy matter, filtration, and precipitation by ammonia. If alcohol be added to the solution previously to the ammonia, the digestion with animal charcoal may be dispensed with, as the alcohol retains the colouring matter. Morphia procured in this way always contains narcotina, from which it may be freed by ether, as directed in the French Codex process, or in some of the modes hereafter to be indicated.

Magnesia was employed by Robiquet instead of ammonia. But his process was soon abandoned; as it was found to occupy more time, to require a greater consumption of alcohol, and to be attended with a greater loss of morphia in consequence of the previous washing, than the processes in which ammonia was employed as the precipitant. For an account of it the reader is referred to former editions of this work.

A process for extracting morphia without the employment of alcohol was devised by MM. Henry, jun., and Plisson. The opium was exhausted by water acidulated with muriatic acid; the resulting solution was sufficiently concentrated, then filtered, and decomposed by ammonia; the precipitate was washed and treated with muriatic acid to saturation; and the muriatic solution was boiled with animal charcoal, filtered, and evaporated to the point of crystallization. The crystals of muriate of morphia thus obtained were pressed, purified by repeated solution and crystallization, and finally decomposed by ammonia. (*Journ. de Chim. Méd.*, Mars, 1828.)

Somewhat similar to this is the process of Gregory, of Edinburgh, by which muriate of morphia is obtained by double decomposition between chloride of calcium and the meconate of morphia of the opium, and the muriate thus ob-

tained is decomposed by ammonia. This process was adopted by the Edinburgh College for the preparation of muriate of morphia; and is imitated by the Dublin College in the elaborate process above given. It will be sufficiently explained under *Muriate of Morphia.*

Mohr has proposed a process founded on the solubility of morphia in water mixed with lime, which he recommends as the shortest and easiest method of procuring the alkali, without the use of alcohol, and without the possibility of contamination from narcotina. Opium is three or four times successively macerated with three parts of water, and each time strongly expressed. The liquors are then added to a boiling-hot milk of lime, containing a quantity of lime equal to about a sixth or a quarter of the opium used; and the mixture is boiled for a few minutes. It is then strained through linen, and the residue washed with boiling water and expressed. The whole of the narcotina is left behind, as not a trace of it can be discovered in the filtered liquor. The liquor thus obtained is evaporated till reduced to double the weight of the opium, then quickly filtered through paper, and heated to ebullition. Muriate of ammonia is now added to it in the proportion of 1 part to 16 of the opium used; and the morphia is abundantly precipitated. The use of animal charcoal is unnecessary in the process, as the lime acts even more powerfully as a decolorizing agent. The crystallized morphia obtained is somewhat coloured, but may be rendered pure by solution in dilute muriatic acid, boiling with milk of lime, filtration, and precipitation by muriate of ammonia. (*Annal. der Pharm.*, xxxv. 119, and *Am. Journ. of Pharm.*, xiii. 60.)

Various other processes, or modifications of those above described, have been proposed; but, for the preparation of small quantities of morphia by the apothecary, none are probably better adapted than that of the U. S. Pharmacopœia, unless indeed the plan of Mohr, should be found to equal the representations in its favour.

It has been already stated that morphia, obtained in the ordinary manner, contains a considerable proportion of narcotina. It is highly probable that this ingredient exercises no influence, either beneficial or injurious, upon the operation of the morphia; but, as the contrary has been supposed, various methods have been employed for separating it. The simplest and easiest is to submit the mixture to the action of ether, which dissolves the narcotina and leaves the morphia. The agency of acetic acid may also be resorted to. Distilled vinegar, or diluted acetic acid of the same strength, will dissolve the morphia and leave the narcotina, and the former may be recovered from the acetic solution by saturating the acid with ammonia. Another mode is to dissolve the mixed bases in strong acetic acid (of 7° Baume, or sp. gr. 1·0511, for example), and expose the solution to heat. The narcotina is deposited, and the morphia, remaining in solution, may be precipitated by diluting the liquid and adding ammonia. (*Journ. de Pharm.*, xvii. 640.) Wittstock advises one of the following modes. Dissolve the impure morphia in dilute muriatic acid, evaporate to the point of crystallization, and strongly express the crystals, which consist solely of the muriate of morphia, the narcotina being retained in the mother waters:—or saturate the muriatic solution with common salt, which will render the liquor milky, and cause the narcotina to separate after some days; then precipitate the morphia by ammonia:—or pour into the diluted muriatic solution a weak ley of caustic potassa, which, if in slight excess, will dissolve the morphia at the moment of its separation, while the narcotina is precipitated; then immediately filter the liquor, and separate the morphia by neutralizing the alkali. If the potassa is in great excess a small portion of the narcotina is redissolved. (*Berzelius Traité de Chimie.*) Mohr recommends to dissolve the morphia in dilute muriatic acid, and to boil the solution with lime, which throws down the nar-

cotina and holds the morphia dissolved. The liquid being filtered yields the morphia upon the addition of muriate of ammonia. (*Annal. der Pharm.*, xxv. 123.)

The proportion of pure morphia which Turkey opium is capable of affording, varies from nine per cent. or less, to fourteen per cent., according to the quality of the drug; but much less than the least quantity mentioned is often obtained, in consequence of the incomplete exhaustion of the opium, the loss in the process for preparing it, or inferiority in the quality of the drug.

Medical Properties. There can be no doubt that morphia is the chief, if not the exclusive narcotic principle of opium, from which, however, it differs somewhat in its mode of action. Whether the difference arises from the peculiar state of combination in which morphia exists in opium, or from other narcotic principles being associated with it, has not been determined; but the former would seem to be the probable cause, from the circumstance that, long before the discovery of this alkali, preparations of opium were habitually used, in which the properties of the medicine were somewhat similarly modified by the agency of vinegar, lemon-juice, or other vegetable acid. In consequence of its insolubility in water, morphia in its pure state is less certain in its effects than some of its saline compounds; as the mode and degree of its action must, in some measure, depend on the presence or absence of acid in the stomach, and perhaps on the peculiar character of the acid. Its salts are therefore always preferred. The acetate, sulphate, and muriate have been employed. Between these there is a great similarity of action, and what may be said of one, in regard to its therapeutical effects, will equally apply to the others. They have the anodyne, soporific, and diaphoretic properties of opium, but are less stimulant, less disposed to constipate the bowels, and less apt to leave behind them headache, nausea, or other unpleasant effect. They are usually also more acceptable to an irritated stomach, and may be retained, when opium or its tincture would be rejected. They are applicable to all cases where the object is to relieve pain, quiet restlessness, promote sleep, or allay nervous irritation in any shape; but are less efficient than opium in the suppression of morbid discharges, and as stimulants in low forms of disease. We have found them especially useful in the mania arising from intemperance. A great advantage which they possess is the convenience of their external application to blistered surfaces, and the certainty of their effects when thus applied. In cases which do not admit of the internal use of opium or its preparations, the acetate or sulphate of morphia, sprinkled, in triple the ordinary dose, upon a blistered surface denuded of the cuticle, will be found to exercise upon the system all the influence it is capable of exerting when taken into the stomach. Applied in this manner, these salts are peculiarly useful in relieving violent neuralgic pains, and controlling obstinate sickness of the stomach. When intended to act on the system through the medium of the skin, they should be applied preferably to the epigastrium; when to act locally, as near the affected part as possible. When given in doses nearly, but not quite sufficient to produce sleep, they sometimes give rise to a very troublesome condition of the brain, amounting almost to delirium; but this always subsides spontaneously, or vanishes immediately upon the increase of the dose. A liniment of morphia for internal use may be made by dissolving the morphia in a little chloroform, and adding the solution to olive or almond oil. The mixture is homogeneous. The chloroform acts merely as a menstruum, being in too small a quantity to produce its own effects on the system. (*Journ. de Pharm.*, 3e *sér.* xxiv. 358.)

In over-doses, morphia and its salts produce the effects of narcotic poisons, though not perhaps equally with a quantity of opium, equivalent in anodyne effect. The toxicological treatment is precisely the same as in the case of lauda-

num. (See *Opium.*) Strong coffee has been employed with great apparent advantage as an antidote.

As the proportion of acid necessary to neutralize morphia is very small, the dose of the alkali is the same as that of its salts. One-sixth of a grain may be considered about equivalent to a grain of opium of the medium strength.

MORPHIÆ ACETAS. *U.S., Lond., Ed., Dub. Acetate of Morphia.*

"Take of Morphia, in powder, freed from narcotina by boiling with Ether, *an ounce;* Distilled Water *half a pint;* Acetic Acid *a sufficient quantity.* Mix the Morphia with the Water; then carefully drop in the Acid, constantly stirring, until the Morphia is saturated and dissolved. Evaporate the solution, by means of a water-bath, to the consistence of syrup. Lastly, dry the Acetate with a gentle heat, and rub it into powder." *U. S.*

The *London College* places this salt in the catalogue of Materia Medica.

"Take of Muriate of Morphia *any convenient quantity.* Dissolve it in *fourteen times its weight* of warm Water, and when the solution is cool, add Aqua Ammoniæ gradually and with constant agitation until there is a permanent but faint odour of ammonia in the fluid. Collect the precipitate on a calico filter, wash it moderately with cold water, and dissolve it by means of a slight excess of Pyroligneous Acid [acetic acid, sp. gr. 1·034] *in twelve parts* of warm Water for *every part* of Muriate of Morphia that was used. Concentrate the solution over the vapour-bath and set it aside to crystallize. Drain and squeeze the crystals, and dry them with a gentle heat. More Acetate of Morphia may be obtained on concentrating the mother liquor." *Ed.*

"Take of Morphia, in fine powder, *one ounce* [avoirdupois]; Rectified Spirit *eight fluidounces;* Acetic Acid of Commerce (sp. gr. 1·044) *four fluidrachms and a half,* or *as much as is sufficient.* Pour the Spirit on the Morphia, and, applying heat, gradually add the Acetic Acid until a neutral or slightly acid solution is obtained. Let this be evaporated to the consistence of syrup, by a steam or water heat, and then set by for a few days, until it solidifies." *Dub.*

In all these processes, morphia is saturated with acetic acid; in the U. S. and Dublin it is taken already prepared; in the Edinburgh, it is procured by the decomposition of the muriate by means of ammonia. Acetic acid is employed in preference to vinegar for saturating the morphia; because it can leave no impurity in the resulting salt. In the U. S. process, the solution of the morphia in the water is an indication that it is saturated. A small excess of acid is attended with no inconvenience, as it is subsequently driven off by the heat. Care is required not to employ too much heat in the evaporation; as the acetate is easily decomposed, a portion of the acetic acid escaping, and leaving an equivalent portion of uncombined morphia. With attention to arrest the evaporation at a certain point, the acetate may be obtained in the state of crystals; but the crystallization is attended with some difficulty, and evaporation to dryness is almost universally preferred. Some recommend to dissolve the morphia in boiling alcohol, instead of suspending it in water, previously to the addition of the acetic acid. A less heat is thus required in the evaporation, and impurities in the morphia may often be detected, as they are apt to be insoluble in alcohol. To ascertain, in this case, whether the morphia is saturated, it is necessary to employ litmus paper, the blue colour of which should not be restored, if previously reddened by an acid. Alcohol is employed as the solvent in the Dublin process. If the morphia used in preparing the acetate contain narcotina, it will be best to employ as the solvent distilled vinegar, or diluted acetic acid of the same strength, and to favour its solvent power by heat. Under these circum-

stances it dissolves only the morphia, leaving the narcotina nearly or quite untouched. (Hodgson, *Journ. of the Phil. Col. of Pharm.*, v. 35.)

Acetate of morphia crystallizes in the form of slender needles united in fasciculi. It is readily dissolved by water, and less easily by alcohol. As ordinarily obtained, however, by evaporation to dryness, it is not entirely soluble in water, a portion of it being uncombined morphia. To render it soluble, all that is necessary is to add a little distilled vinegar. The U. S. Pharmacopœia gives the following tests of its character. "From its solution potassa throws down a precipitate which is dissolved by an excess of the alkali. It is affected by heat, nitric acid, and sesquichloride of iron, in the same manner as morphia. When sulphuric acid is added to the salt, acetous vapours are evolved." In addition to these tests, the *London College* refers to the property, possessed by this and other salts, when treated first with chlorine, and then with ammonia, of presenting a brown colour, which disappears on the further addition of chlorine. The *Edinburgh College* gives the following mode of testing its purity: "One hundred measures of a solution of ten grains in half a fluidounce of water and five minims of acetic acid, heated near to 212°, and decomposed by a faint excess of ammonia, yield by agitation a precipitate which in 24 hours occupies 15·5 measures of the liquid."

From an eighth to a quarter of a grain may be given for a dose, and repeated, if necessary, in order to obtain the anodyne and soporific effects of the medicine. One-sixth of a grain is about equivalent to a grain of opium. It may be given in pill or solution. It is frequently employed externally, sprinkled on blistered surfaces, to obtain its effects upon the system.

Off. Prep. Liquor Morphiæ Acetatis. W.

LIQUOR MORPHIÆ ACETATIS. *Lond., Dub. Solution of Acetate of Morphia.*

"Take of Acetate of Morphia *four drachms;* Acetic Acid *fifteen minims;* Distilled Water *a pint* [Imperial measure]; Proof Spirit *half a pint* [Imp. meas.]. Mix and dissolve." *Lond.*

"Take of Acetate of Morphia *eighty-two grains;* Rectified Spirit *five fluidounces;* Distilled Water *fifteen* [*fluid*]*ounces.* Having added the Spirit to the Water, dissolve the Acetate of Morphia in the mixture, and, if the solution is not quite clear, pass it through a paper filter." *Dub.*

The object of the Spirit in these solutions is to aid in their preservation. As the acetate often contains some uncombined morphia, in consequence of the partial escape of acetic acid during the evaporation in preparing it, the London College very properly directs a little acetic acid for its solution. The Dublin College less wisely wastes it by filtration. Unfortunately the solutions of the two Colleges are of unequal strength, the London being about twice as strong as the Dublin. The dose of the London solution is from 7·5 to 15 minims, equivalent to from one-eighth to one-quarter of a grain of the salt; that of the Dublin solution is from 15 to 30 minims. The latter was intended to have the same strength as laudanum.

Off. Prep. Syrupus Morphiæ Acetatis. W.

MORPHIÆ MURIAS. *U.S., Ed., Dub.* MORPHIÆ HYDROCHLORAS. *Lond. Muriate of Morphia. Hydrochlorate of Morphia.*

"Take of Morphia, in powder, *an ounce;* Distilled Water *half a pint;* Muriatic Acid *a sufficient quantity.* Mix the Morphia with the Water; then carefully drop in the Acid, constantly stirring, till the Morphia is saturated and dissolved. Evaporate the solution by means of a water-bath, so that it may crystallize upon cooling. Dry the crystals upon bibulous paper." *U. S.*

The *London College* has transferred muriate of morphia to the Materia Medica list.

"Take of Opium *twenty ounces;* Water *eight pints* [Imperial measure]; Muriate of Lime [chloride of calcium] *one ounce,* or *a slight excess.* Macerate the Opium in fragments for twenty-four hours in two pints of the Water; and separate the infusion, squeezing well the residue. Repeat the maceration successively with two pints more of the Water till the whole is made use of. Concentrate the whole infusions over the vapour-bath to one pint, and add the Muriate of Lime dissolved in four fluidounces of Water. Set the whole aside to settle; pour off the liquid; wash the sediment with a little water, adding the washings to the liquid. Evaporate the liquid sufficiently in the vapour-bath for it to solidify on cooling. Subject the cooled mass to very strong pressure in a cloth; redissolve the cake in a sufficiency of warm distilled water; add a little fine powder of white marble, and filter; acidulate the filtered fluid with a very little muriatic acid; and concentrate a second time in the vapour-bath for crystallization. Subject the crystals again to very strong pressure in a cloth. Repeat the process of solution, clarification by marble and muriatic acid, concentration, and crystallization, until a snow-white mass be obtained.

"On the small scale trouble and loss are saved by decolorizing the solution of muriate of morphia by means of a little purified animal charcoal after two crystallizations. But on the large scale it is better to purify the salt by repeated crystallizations alone, and to treat all the expressed fluids, except the first, in the same way with the original solution of impure muriate of morphia. An additional quantity of salt may often be got from the first dark and resinous fluid obtained by expression, on merely allowing it to remain at rest for a few months, when a little muriate of morphia may be deposited in an impure condition.

"The opium which yields the largest quantity of precipitate by carbonate of soda, according to the formula [given in *page* 538], yields muriate of morphia not only in greatest proportion, but likewise with the fewest crystallizations." *Ed.*

"Take of Morphia, in fine powder, *one ounce* [avoirdupois]; Pure Muriatic Acid *four fluidrachms and a half,* or *a sufficient quantity;* Distilled Water *two* [*fluid*]*ounces and a half.* Mix the Acid with the Water, heat to about 200°, and add the Morphia, constantly stirring, so that a solution may be formed having a slightly acid reaction. Set this to cool for twelve hours, and let the crystals which separate be drained of the liquor which surrounds them, and dried on blotting paper. The decanted liquor will, by further concentration and cooling, give additional crystals." *Dub.*

In relation to the process of the U. S. Pharmacopœia, the remarks made upon the preparation of the sulphate of morphia are equally applicable here. (See *Morphiæ Sulphas.*) The Dublin process differs from that of the U. S. Pharmacopœia only in employing heat in effecting the solution of the morphia in the diluted acid, so as to lessen the amount of subsequent evaporation, and in directing a slight excess of acid. The Edinburgh process is based upon the plan, originally suggested by Wittstock, of obtaining muriate of morphia immediately from opium without the use of alcohol. It is that of Dr. Wm. Gregory, which is an improvement on Wittstock's. The meconate and a little sulphate of morphia extracted by water from opium are decomposed by chloride of calcium, yielding muriate of morphia in solution, and meconate and sulphate of lime as precipitates. The remaining steps consist in obtaining the muriate of morphia from the solution by evaporation and crystallization, and in freeing it from colouring impurities. For the latter purpose the College directs repeated solution, clarification by marble and muriatic acid, concentration, and crystallization; advising, when the process is conducted upon a small scale, the use of animal charcoal after two crystallizations. It prevents waste by operating upon

all the liquids expressed from the impure muriate of morphia, except that separated by the first expression, in the same manner as upon the original solution. Points deserving of particular notice in the process are, to obtain the infusion of opium as concentrated as possible without leaving morphia behind, so as to shorten the period of evaporation; and to add the chloride of calcium before instead of after the concentration, as, according to Christison, a larger and purer product is obtained, in the former way, with fewer crystallizations. Dr. Christison says, in favour of Dr. Gregory's process, that the Edinburgh manufacturers, who follow it, produce a salt of unrivalled purity and cheapness. But it is much better calculated for the large laboratory of the manufacturing chemist, than for the smaller operations of the apothecary, who will probably find the U. S. process more convenient.

Muriate of morphia procured by the process of the Edinburgh College is free from narcotina; but always contains a portion of muriate of codeia, which, however, is scarcely sufficient to affect its operation upon the system. Dr. Christison found the proportion to vary between a 60th in the muriate prepared from good Turkey opium, a 30th in that from inferior samples of the same variety, and a 12th in that from the East Indian. This impurity may be separated by precipitating the morphia by means of ammonia; the codeia being left in solution.

The late Dr. A. T. Thomson published a process for procuring muriate of morphia, which he found considerably more productive than that of the British Colleges. After macerating the opium in water, as directed by the Colleges, for thirty hours, and expressing, he rubbed it in a mortar with an equal weight of pure white sand, and enough water to form the mixture into a paste, which he placed in a percolator, and subjected to the action of distilled water till the fluid passed without colour and taste. He then concentrated the liquor to the consistence of a thin syrup, added diacetate of lead, diluted the solution with twice its bulk of distilled water, allowed it to stand for twenty-four hours, decanted the supernatant liquid, washed the precipitate with warm water, added the washings to the decanted solution, and concentrated to one-half. To free the liquid from any remaining acetate of lead, he added diluted sulphuric acid in slight excess, decanted the liquid from the precipitate, washed the latter, added the washings to the solution, and boiled for some minutes to drive off acetic acid. To convert the sulphate of morphia now contained in the solution into muriate, he added a saturated solution of chloride of barium, washed the precipitate, evaporated the conjoined washings and solution to the point of crystallization, pressed the crystals, diluted and again evaporated the mother liquor so long as it afforded crystals, which were purified by means of animal charcoal, and by repeated solution, evaporation, and crystallization. (*Pharm. Journ.*, i. 459.)

Muriate of morphia crystallizes in tufts of feathery acicular crystals. It is white, inodorous, bitter, soluble in 16 parts of water at 60°, and in its own weight at 212°, and soluble also in alcohol. A saturated solution in boiling water forms a solid crystalline mass on cooling. The crystals are said to consist of one equivalent of morphia 292, one of muriatic acid 36·42, and six of water 54. Dr. Christison states that he constantly found the crystals, when dried at 150°, to contain 12·7 per cent. of water; and the Edinburgh College states that the loss of weight at 212° is not above 13 per cent. The salt may be known to be a muriate by yielding in solution with nitrate of silver, a precipitate insoluble in nitric or muriatic acid, but dissolved by an excess of ammonia. Potassa throws down from its solution a precipitate which is redissolved by an excess of the alkali. The salt is affected by heat, nitric acid, sesquichloride of iron, and chlorine followed by ammonia, in the same manner as morphia. Sugar is said to have been used largely in the adulteration of this salt. It may be detected by the test of fermentation.

This preparation of morphia is much used in Great Britain, but, in this country, less than either the sulphate or acetate. The dose, equivalent to a grain of opium, is about one-sixth of a grain.

Off. Prep. Liquor Morphiæ Muriatis; Morphiæ Acetas; Trochisci Morphiæ; Trochisci Morphiæ et Ipecacuanhæ. W.

LIQUOR MORPHIÆ MURIATIS. *Dub.* MORPHIÆ MURIATIS SOLUTIO. *Ed.* LIQUOR MORPHIÆ HYDROCHLORATIS. *Lond.* *Solution of Muriate of Morphia.* *Solution of Hydrochlorate of Morphia.*

"Take of Hydrochlorate of Morphia *four drachms;* Distilled Water *a pint* [Imperial measure]; Proof Spirit *half a pint* [Imperial measure]. Mix and dissolve." *Lond.*

"Take of Muriate of Morphia *one drachm and a half;* Rectified Spirit *five fluidounces*; Distilled Water *fifteen fluidounces.* Mix the Spirit and Water, and dissolve the Muriate of Morphia in the mixture with the aid of a gentle heat." *Ed.*

"Take of Muriate of Morphia *ninety grains;* Rectified Spirit *five fluidounces;* Distilled Water *fifteen* [*fluid*]*ounces.* Mix the Spirit and Water, dissolve the Muriate of Morphia in the mixture, and, unless the solution be quite clear, pass it through a paper filter." *Dub.*

The use of the alcohol is to prevent spontaneous decomposition. It is extremely unfortunate that, in the solutions of the salts of morphia, the same degree of strength should not have been directed by the different Pharmacopœias. As they now are, the medical practitioner and apothecary must be constantly on their guard to avoid the most serious results. One grain of the muriate of morphia is contained in 60 minims of the London solution, and in 106·66 minims of the Edinburgh and Dublin solutions which are identical. The dose, therefore, is from 7·5 to 15 minims of the London, and from 13 to 26 minims of the Edinburgh and Dublin solution, equivalent to from one-eighth to one-quarter of a grain of the dry salt. The Edinburgh and Dublin preparation was intended to have the medium strength of laudanum.

Off. Prep. Syrupus Morphiæ Muriatis. W.

MORPHIÆ SULPHAS. *U.S.* *Sulphate of Morphia.*

"Take of Morphia, in powder, *an ounce;* Distilled Water *half a pint;* Diluted Sulphuric Acid *a sufficient quantity.* Mix the Morphia with the Water, then carefully drop in the Acid, constantly stirring till the Morphia is saturated and dissolved. Evaporate the solution by means of a water-bath, so that it may crystallize upon cooling. Dry the crystals upon bibulous paper." *U. S.*

In this process the morphia is known to be saturated when it is wholly dissolved by the water. To ascertain whether the acid is added in excess, litmus paper may be resorted to. If the morphia employed contain narcotina, this will remain in the mother liquor, and will not contaminate the product. The mother liquor remaining after the first crystallization may be evaporated so as to afford a fresh supply of the sulphate; but, if the morphia was not originally quite pure, the second product will contain the impurities, and should not be used till it has undergone further preparation. When impure morphia is employed, the mother liquor should be mixed with alcohol, or boiled with purified animal charcoal and filtered, and then decomposed by ammonia, which will precipitate the morphia. This may be converted into the sulphate in the manner directed by the Pharmacopœia.

Another mode of obtaining sulphate of morphia, is to dissolve the alkali in boiling alcohol of 36° Baumé (sp. gr. 0·8428), saturate it while hot with sulphuric acid, add purified animal charcoal, boil for a few minutes, and filter the solution while at the boiling temperature. Upon cooling, it deposits most of the sulphate; and the remainder may be obtained by evaporating the mother liquor.

In the evaporation of the solution of this salt, care should be taken not to carry the heat too far; for when pushed to incipient decomposition with an excess of acid, a new substance is formed containing no morphia. (See *Am. Journ. of Pharm.*, xvii. 286.)

Sulphate of morphia crystallizes in beautifully white, minute, feathery crystals, which are soluble in cold water, and in twice their weight of boiling water. They contain, according to Liebig, in 100 parts, 10·33 of sulphuric acid, 75·38 of morphia, and 14·29 of water. By exposure to a heat of 248° F. they lose 9·66 parts of the water, but cannot be deprived of the remainder without decomposition. Their equivalent composition is stated to be one equivalent of morphia 292, one of sulphuric acid 40, and six of water 54, of which five are water of crystallization, and may be expelled by heat. The tests for it are those for sulphuric acid and for morphia.

The dose of sulphate of morphia is from an eighth to a quarter of a grain, which may be given in pill or solution.

Off. Prep. Liquor Morphiæ Sulphatis. W.

LIQUOR MORPHIÆ SULPHATIS. *U. S.* *Solution of Sulphate of Morphia.*

"Take of Sulphate of Morphia *eight grains;* Distilled Water *half a pint.* Dissolve the Sulphate of Morphia in the Water." *U. S.*

Sulphate of morphia, as found in the shops, is not always entirely soluble in water. This sometimes, perhaps, arises from adulterations; but more frequently, in all probability, from the mode of preparing the sulphate. As this salt was formerly prepared, the quantity of water employed for the suspension of the morphia was sometimes insufficient to hold the resulting sulphate in solution; and the consequence was that, upon the addition of sulphuric acid, the crystallization of the sulphate took place before the whole of the morphia was saturated by the acid. A portion of uncombined morphia was therefore necessarily mixed with the salt. Under such circumstances, the addition of a little sulphuric acid usually remedied the defect, and rendered the whole soluble. Pure sulphate of morphia is readily and entirely soluble in water.

This solution is very convenient, by enabling the physician to prescribe a minute dose, which, in consequence of the great energy of the preparations of morphia, is often necessary. It has the advantage that it may be kept for a very considerable length of time unchanged. The full dose for an adult is from one to two fluidrachms, containing from an eighth to a quarter of a grain of the sulphate.

Unfortunately, in some parts of the Union, the formula of Magendie for this solution, containing 16 grains in a fluidounce, is habitually employed under the name of solution of sulphate of morphia. This is the proper name of the officinal solution, which is much weaker; and the most dangerous results may ensue from the confusion. Magendie's solution should never be prescribed or sold unless under some special designation. W.

MUCILAGINES.

Mucilages.

Mucilage, in the ordinary acceptation of the term, and in the sense in which it is employed in the U. S. Pharmacopœia, is an aqueous solution of gum, or of substances closely allied to it. As used by the British Colleges it appears to signify any bland, viscid, aqueous, vegetable solution resembling that of gum in sensible properties. W.

MUCILAGO ACACIÆ. *U. S., Dub.* Mucilago. *Ed.* Mistura Acaciæ. *Lond. Mucilage of Gum Arabic.*

"Take of Gum Arabic, in powder, *four ounces;* Boiling Water *half a pint.* Add the Water gradually to the Gum, rubbing them together till the mucilage is formed." *U. S.*

The *London College* takes *ten ounces* of powdered gum Arabic, and *a pint* [Imperial measure] of boiling distilled water, and proceeds as above. The *Edinburgh College* directs *nine ounces* of gum Arabic to be dissolved in *a pint* [Imp. meas.] of cold water, without heat, but with occasional stirring, and then to be strained through linen or calico. The *Dublin College* takes *four ounces* (avoirdupois) of the gum, and *six* [*fluid*]*ounces* of water, dissolves the gum with occasional stirring, and strains through flannel.

The gum used for this purpose should be in the state of a coarse powder, as it is more readily dissolved in this state than when finely pulverized. Straining is necessary to separate the foreign substances which are often mixed with gum Arabic. This mucilage is semitransparent, almost colourless if prepared from good gum, viscid, tenacious, of a feeble peculiar odour, and nearly tasteless. If the solution of gum should be coloured, it may be rendered colourless by the addition of a concentrated solution of chlorine; and, by boiling for about half an hour so as to drive off the chlorine and muriatic acid, it may be rendered fit for use. (*Guérin.*) By keeping, mucilage becomes sour, in consequence of the spontaneous generation of acetic acid; and this happens even though it be enclosed in well-stopped bottles. But, according to M. Guérin, the aqueous solution of pure gum undergoes no change in vacuo. Heat in its preparation is said to favour the production of acid, in which case the Edinburgh or Dublin formula is preferable. Mucilage is employed chiefly in the formation of pills, and for the suspension or diffusion of insoluble substances in water. Physicians, in prescribing mucilage in mixtures, should always recollect that it is a solution of definite strength, containing half an ounce of the gum in each fluidounce. Half a fluidounce is usually sufficient for a six or eight ounce mixture.

Off. Prep. Mistura Acaciæ; Mistura Amygdalarum; Mistura Cretæ; Mistura Guaiaci. W.

MUCILAGO AMYLI. *Ed., Dub.* Decoctum Amyli. *Lond. Mucilage of Starch.*

"Take of Starch *four drachms;* Water *a pint* [Imperial measure]. Rub the Starch with the Water gradually added; then boil for a short time." *Lond.*

The *Edinburgh College* takes *half an ounce* of starch and *a pint* [Imp. meas.] of water; the *Dublin, half an ounce* [avoirdupois] of the former, and *half a pint* [Imp. meas.] of the latter; both proceed according to the directions of the London College.

This mucilage has an opaline appearance, and gelatinous consistence, and is much used as a vehicle for laudanum and other active medicines given in the form of enema. In consequence of its demulcent properties, it may be usefully employed as an enema in irritation and inflammation of the mucous coat of the rectum and large intestines. Its unpleasant flavour, when it is prepared from ordinary starch, precludes its employment by the mouth.

Off. Prep. Enema Opii. W.

MUCILAGO HORDEI. *Dub. Mucilage of Barley.*

"Take of ground Pearl Barley *half an ounce* [avoirdupois]; Water *sixteen* [*fluid*]*ounces.* Triturate the Barley with the Water gradually added; then boil for a few minutes." *Dub.*

This is intended simply as an emollient enema, or as a vehicle of other substances given in that form.

Off. Prep. Enema Catharticum; Enema Terebinthinæ. W.

MUCILAGO TRAGACANTHÆ. *U. S., Ed. Mucilage of Tragacanth.*

"Take of Tragacanth *an ounce;* Boiling Water *a pint.* Macerate the Tragacanth in the Water for twenty-four hours, occasionally stirring; then triturate it so as to render the mucilage uniform, and strain forcibly through linen." *U. S.*

The *Edinburgh College* takes *two drachms* of tragacanth and *nine fluidounces* of boiling water, macerates for twenty-four hours, then triturates, and expresses through linen or calico.

A part only of tragacanth is soluble in water. The remainder swells up and forms a soft tenacious mass, which may be mechanically mixed with water, but does not form a proper solution. Hence trituration is necessary to complete the incorporation of the ingredients. This mucilage is thick and very viscid, but not permanent, as the water separates from the insoluble portion of the tragacanth on standing. It is chiefly used in making pills and troches. In consequence of its great tenacity, it may be advantageously employed for the suspension of heavy insoluble substances, such as the metallic oxides in water.

OLEA DESTILLATA.

Distilled Oils.

For an account of the general properties of the volatile, essential, or distilled oils, the reader is referred to the head of *Olea Volatilia* in the first part of this work. The following are the different officinal directions for preparing them.

OLEA DESTILLATA. *U. S.*

"In the preparation of the Distilled Oils, put the substance from which the oil is to be extracted into a retort, or other vessel suitable for distillation, and add enough water to cover it, then distil into a large refrigeratory. Separate the Distilled Oil from the water which comes over with it.

"In this manner prepare Oil of Anise, from Anise; Oil of Caraway, from Caraway; Oil of Cloves, from Cloves; Oil of Wormseed, from Wormseed; Oil of Cubebs, from Cubebs; Oil of Fennel, from Fennel-seed; Oil of Partridge-berry, from Partridge-berry [leaves]; Oil of Pennyroyal [Oleum Hedeomæ], from Pennyroyal; Oil of Juniper, from Juniper [berries]; Oil of Lavender, from Lavender [flowers]; Oil of Peppermint, from Peppermint; Oil of Spearmint, from Spearmint; Oil of Horsemint, from Horsemint; Oil of Origanum, from Origanum [Marjoram]; Oil of Pimento, from Pimento; Oil of Rosemary, from Rosemary [tops]; Oil of Savine, from Savine; Oil of Sassafras, from Bark of Sassafras Root; and Oil of Valerian, from Valerian." *U. S.*

The *London College* gives no directions for the preparation of the volatile oils, but places such as it recognises in the Materia Medica catalogue.

VOLATILE OILS. *Ed.*

"Volatile oils are obtained chiefly from the flowers, leaves, fruit, barks, and roots of plants, by distilling them with water, in which they have been allowed to macerate for some time. Flowers, leaves, and fruits generally yield the finest oils, and in greatest quantity, when they are used fresh. Many, however, answer equally well if they have been preserved by beating them into a pulp with

about twice their weight of muriate of soda, and keeping the mixture in well-closed vessels.

"Substances yielding volatile oils must be distilled with water, the proper proportion of which varies for each article, and for the several qualities of each. In all instances, the quantity must be such as to prevent any of the material from being empyreumatized before the whole oil is carried over. In operations where the material is of pulpy consistence, other contrivances must be resorted to for the same purpose. These consist chiefly of particular modes of applying heat, so as to maintain a regulated temperature not much above 212°. On the small scale, heat may be thus conveniently applied by means of a bath of a strong solution of muriate of lime, or by means of an oil-bath, kept at a stationary temperature with the aid of a thermometer. On the large scale, heat is often applied by means of steam under regulated pressure. In other operations it is found sufficient to hang the material within the still in a cage or bag of fine net-work; and sometimes the material is not mingled with the water at all, but is subjected to a current of steam passing through it.

"The best mode of collecting the oil is by means of the refrigeratory described in the preface [see *page* 793], from which the water and oil drop together into a tall narrow vessel, provided with a lateral tube or lip near the top, and another tube rising from the bottom to about a quarter of an inch below the level of the former. It is evident that with a receiver of this construction, the water will escape by the lower tube; while the volatile oil, as it accumulates, will be discharged by the upper one, except in the very few instances where the oil is heavier than the water.

"By attending to the general principles now explained, Volatile Oils may be readily obtained of excellent quality from the flowers of ANTHEMIS NOBILIS, LAVANDULA VERA, and RUTA GRAVEOLENS; from the fruit of ANETHUM GRAVEOLENS bruised, CARUM CARUI bruised, EUGENIA PIMENTA bruised, FŒNICULUM OFFICINALE bruised, JUNIPERUS COMMUNIS bruised, PIPER CUBEBA ground, and PIMPINELLA ANISUM ground; from the undeveloped dried flowers of CARYOPHYLLUS AROMATICUS; from the tops of JUNIPERUS SABINA and ROSMARINUS OFFICINALIS; from the entire herb of MENTHA PIPERITA, MENTHA PULEGIUM, MENTHA VIRIDIS, and ORIGANUM MAJORANA [vulgare?]; and also from the bruised root of SASSAFRAS OFFICINALE." *Ed.*

OILS. *Dub.*

"The VOLATILE OR ESSENTIAL OILS may be obtained by the following general process. The substance from which the oil is to be extracted is macerated for twenty-four hours, with five times its weight of water, in a sheet-tin or copper still, and, a condenser being then attached, half the water is drawn over by distillation, on the surface of which the oil will be found to float, unless (which is rarely the case) it should be heavier than water, when it will be found at the bottom of the receiver. The oil having been separated, the aqueous product, which is a saturated solution of the oil in water, is to be returned to the still, and the distillation resumed, and continued till the resulting liquid has the same volume as before. The oil is again separated, the watery product returned to the still, and the distillation resumed; and this process is to be repeated until it ceases to afford any additional oily product. The oil thus obtained is to be separated as completely as possible from water, and preserved in a well-stopped bottle.

"In this way volatile oils may be obtained from the entire herb of MENTHA PIPERITA. MENTHA PULEGIUM, MENTHA VIRIDIS; from the seeds or fruit of CARUM CARUI, CUBEBA OFFICINALIS, EUGENIA PIMENTA, FŒNICULUM OFFI-

CINALE, JUNIPERUS COMMUNIS, MYRISTICA MOSCHATA, PIMPINELLA ANISUM; from the flowers of ANTHEMIS NOBILIS, LAVANDULA VERA; from the undeveloped dried flowers of CARYOPHYLLUS AROMATICUS; from the tops of JUNIPERUS SABINA, ROSMARINUS OFFICINALIS; from the bark of CINNAMOMUM ZEYLANICUM.

"The water distilled over in the preparation of the several oils should be preserved for medical use." *Dub.*

The substances from which the volatile oils are extracted may be employed either in the recent or dried state. Certain flowers, however, such as orange flowers and roses, must be used fresh, or preserved with salt, as they afford little or no oil after exsiccation. Most of the aromatic herbs, also, as peppermint, spearmint, pennyroyal, and marjoram, are usually distilled while fresh; although it is thought by some that, when moderately dried, they yield a larger and more grateful product. Dried substances, before being submitted to distillation, require to be macerated in water till they are thoroughly penetrated by this fluid; and, to facilitate the action of the water, it is necessary that, when of a hard or tough consistence, they should be properly comminuted by slicing, shaving, rasping, bruising, or other similar mechanical operation.

The water which is put with the subject of distillation into the alembic, answers the double purpose of preventing the decomposition of the vegetable matter by regulating the temperature, and of facilitating the volatilization of the oil, which, though in most instances it readily rises with the vapour of boiling water, requires, when distilled alone, a considerably higher temperature, and is at the same time liable to be partially decomposed. Some oils, however will not ascend readily with steam at 212°; and in the distillation of these it is customary to use water saturated with common salt, which does not boil under 230°. Recourse may also be had to a bath of strong solution of chloride of calcium, or to an oil-bath, the temperature of which is regulated by a thermometer, as suggested by the Edinburgh College in their general directions (see *page* 1095). Other oils again may be volatilized with water at a temperature below the boiling point; and, as heat exercises an injurious influence over the oils, it is desirable that the distillation should be effected at as low a temperature as possible. To prevent injury from heat, it has been recommended to suspend the substance containing the oil in a basket, or to place it upon a perforated shelf, in the upper part of the alembic, so that it may be penetrated by the steam, without being in direct contact with the water. Another mode of effecting the same object is to distil it *in vacuo*. Dr. Duncan stated that the most elegant volatile oils he had ever seen were prepared in this manner by Mr. Barry, the inventor of the process. The employment of steam heat also prevents injury; and the best volatile oils are now prepared in Philadelphia in this way. Steam can be very conveniently applied to this purpose by causing it to pass through a coil of leaden tube of an inch or three-quarters of an inch bore, placed in the bottom of a common still. The end at which the steam is admitted enters the still at the upper part, and the other end at which the steam and condensed water escape, passes out laterally below, being furnished with a stop-cock, by which the pressure of the steam may be regulated, and the water drawn off if necessary. In some instances, it has been found desirable to conduct the steam immediately into the still near the bottom, by which the contents are kept in a state of brisk ebullition. This method is used in the preparation of the oil of bitter almonds and the oil of mustard. The same method is applicable to the preparation of the distilled waters. (Soubeiran, *Trait. de Pharm.*, 3e ed., i. 423.)

The quantity of water added is not a matter of indifference. An excess above what is necessary acts injuriously by holding the oil in solution, when the mixed vapours are condensed; and, if the proportion be very large, it is possible that

no oil whatever may be obtained separate. On the contrary, if the quantity be too small, the whole of the oil will not be distilled; and there will be danger of the substance in the alembic adhering to the sides of the vessel, and thus becoming burnt. Enough water should always be added to cover the solid material, and prevent this latter accident. Dried plants require more water than those which are fresh and succulent. The whole amount of materials in the alembic should not exceed three-fourths of its capacity; as otherwise there would be danger of the liquor boiling over. The form of the alembic has a considerable influence over the quantity of water distilled, which depends more upon the extent of surface than the amount of liquid submitted to evaporation. By employing a high and narrow vessel, we may obviate the disadvantage of an excess of water. The broad shallow alembic, suitable for the distillation of alcohol and the spirituous liquors, will not answer so well in this case. Sometimes the proportion of oil contained in the substance employed is so small that it is wholly dissolved in the water distilled, even though the proportion of the liquid in the alembic is not greater than is absolutely essential. In this case it is necessary to redistil the same water several times from fresh portions of the plant, till the quantity of oil which comes over exceeds its solvent power. This process is called *cohobation.*

The more volatile of the oils pass with facility along with the steam into the neck of the common still; but some which are less volatile are apt to condense in the head, and thus return into the alembic. For the distillation of the latter, a still should be employed with a large and very low head, having a rim or gutter around its internal circumference, into which the oils may be received as they condense, and thence pass into the neck. As, after the distillation of any one oil, it is necessary that the apparatus should be thoroughly cleansed before being used for the preparation of another, it is better that the condensing tube should be straight, than spiral as in the ordinary still. It should be recollected, moreover, that certain oils, such as those of anise and fennel, become solid at a comparatively high temperature; and that, in the distillation of these, the water employed for refrigeration should not be below 42° F.

The mixed vapours are condensed into a milky liquid, which is collected in a receiver, and, after standing for some time, separates into a clear solution of the oil in water, and into the oil itself; the latter floating on the surface, or sinking to the bottom, according as it is lighter or heavier than water. The distillation should be continued so long as the fluid which comes over has this milky appearance.

The last step in the process is to separate the oil from the water. For this purpose the *Florence receiver* may be used. This is a conical glass vessel, broad at the bottom and narrow towards the top, and very near its base furnished with a tubulure or opening, to which is adapted, by means of a pierced cork, a bent tube so shaped as to rise perpendicularly to seven-eighths of the height of the receiver, then to pass off from it at right angles, and near the end to bend downwards. The condensed liquid being admitted through the opening at the top of the receiver, the oil separates, and rising to the top, occupies the upper narrow part of the vessel, while the water remains at the bottom and enters the tube affixed to the receiver. When the surface of the liquid attains in the receiver a higher level than the top of the tube, the water will necessarily begin to flow out through the latter, and may be received in bottles. The oil thus accumulates so long as the process continues; but it is evident that the plan is applicable only to the oils lighter than water. For the heavier oils, cylindrical vessels may be employed, to be renewed as fast as they are filled. But, as all the water cannot be removed by these plans, it is necessary to resort to some other method of effecting a complete separation. An instrument called a *separatory* is usually employed for this purpose. It consists of a glass funnel, bulging at

the top, where it is furnished with a stopper, and prolonged at the bottom into a very narrow tube. (See *figure, page* 775.) The lower opening being closed, the mixed liquids are introduced and allowed to stand till they separate. The orifice at the bottom is then opened, and the stopper at top being a little loosened so as to admit the air, the heavier liquid slowly flows out, and may be separated to the last drop from the lighter, which floats above it. If the oil is heavier than the water, it passes out of the separatory; if lighter it remains within. Another mode of separating the oil is to introduce into the vessel containing the two liquids one end of a cord of cotton, the other end hanging out, and terminating in a suitable receptacle beneath the level of that immersed in the liquid. The oil at top passes through the cord, and may thus be wholly removed. The last drops may be collected by pressing the cord between the fingers.

The water saturated with oil should be preserved for future distillations; as it can dissolve no more of the oil, and will therefore yield a larger product.

When first procured, the oil has a disagreeable empyreumatic odour, from which it may be freed by allowing it to stand for some days in vessels loosely covered with paper. It should then be introduced into small opaque bottles, which should be well stopped so as to exclude the air. When altered by exposure to air, the oils may sometimes be nearly or quite restored to their original appearance and quality by agitation with a little recently heated animal charcoal; and the same method may be employed for freeing oils from adhering water.

The volatile oils have the medical properties of the plants from which they are derived; and, as their remedial application has been mentioned under the heads of these plants respectively, it will be unnecessary to treat of it in this place. They may be administered dropped on a lump of sugar; or triturated with at least ten times their weight of sugar, forming an *oleo-saccharum*, and then dissolved in water; or made into an emulsion with water, sugar, and gum Arabic. They are frequently kept dissolved in alcohol under the name of *essences.** W.

OLEUM ANETHI. *Lond., Ed. Oil of Dill.*

The fruit of dill yields about 3·5 per cent. of volatile oil. This is of a pale-yellow colour, with the odour of the fruit, and a hot sweetish taste. Its specific gravity is stated at 0·881. It is employed to prepare dill water, and may be given as a carminative in the dose of three or four drops; but it is little used in this country.

OLEUM ANISI. *U.S., Lond., Ed., Dub. Oil of Anise.*

The product of oil from anise is variously stated from 1·56 to 3·12 per cent. The oil employed in this country is imported. It is colourless or yel-

* It is often important to know how many drops a volatile oil will yield to the fluidrachm, in other words the relation of a drop of the oil to a minim. This varies extremely according to the circumstances elsewhere noticed as influencing the size of the drop; so that any results obtained are only approximate and relative. At our request Professor Procter tried the following oils, with the results stated in the table below. The columns of figures represent the number of drops in a fluidrachm of the oils respectively, the first column giving those obtained by dropping the oils from the bottles in which they are commonly kept, the second by dropping them from a minim measure.

Oleum Anisi	85– 86	Oleum Fœniculi	103–103	Oleum Rosmarini	104–105
" Carui	106–108	" Gaultheriæ	102–101	" Sabinæ	102–108
" Caryophylli	103–103	" Hedeomæ	91– 91	" Sassafras	102–100
" Chenopodii	97–100	" Menthæ Piperitæ	103–109	" Tanaceti	92–111
" Cinnamomi	100–102	" Menthæ Viridis	89– 94	" Valerianæ	116–110
" Cubebæ	86– 96			Creasotum	95– 91

lowish, with the peculiar odour and taste of the seed. At 50° it crystallizes in flat tables, and does not melt under 62°. Its sp. gr. increases with age, and is variously given from 0·9768 to 0·9903. It is soluble in all proportions in alcohol of 0·806; but alcohol of 0·840 dissolves at 77° only 42 per cent. It consists of two oils, one solid at ordinary temperatures and heavier than water (*stearoptene*), the other liquid and more volatile (*eleoptene*), both of which are said to have the same atomic constitution, and to consist of carbon, hydrogen, and oxygen ($C_{10}H_6O$). It absorbs oxygen from the air, and becomes less disposed to concrete. Oil of anise is said to be sometimes adulterated with spermaceti, wax, or camphor. The first two may be detected by their insolubility in cold alcohol, the last by its odour. The dose of the oil is from five to fifteen drops. Its comparative mildness adapts it to infantile cases. We are informed that the oil of anise has, in this country, been almost entirely superseded by the *oil of star aniseed* (*oleum badiani*), which closely resembles it in flavour. (See *page* 101.)

OLEUM ANTHEMIDIS. *Lond., Ed., Dub. Oil of Chamomile.*

This is seldom prepared or used in this country. Baumé obtained thirteen drachms of the oil from eighty-two pounds of the flowers; according to Mr. Brande, the average product of 100 pounds is two pounds twelve ounces. It has the peculiar smell of chamomile, with a pungent somewhat aromatic taste. When recently distilled it is of a sky-blue colour, which changes to yellow or brownish on exposure. The sp. gr. of the English oil is said to be 0·9083. According to M. Gerhardt, oil of chamomile is a mixture of a carbohydrogen ($C_{20}H_{16}$) with an oxygenated oil ($C_{10}H_6O_2$). (*Chem. Gaz.* vi. 483.) It has sometimes been used in spasm of the stomach, and as an adjunct to purgative medicines. The dose is from five to fifteen drops.

On the continent of Europe, an oil extracted from *Matricaria Chamomilla* is employed under the name of oil of chamomile. It is dark-blue, thick, and nearly opaque, becoming brown and unctuous by time. It has the odour of the plant from which it is derived, and an aromatic taste. W.

OLEUM CARI. *U.S.* Oleum Carui. *Lond., Ed. Dub. Oil of Caraway.*

This oil is prepared to a considerable extent by our distillers. The fresh fruit yields on an average about 4·7 per cent. (Recluz); but the product is very variable. The oil of caraway is somewhat viscid, of a pale-yellow colour becoming brownish by age, with the odour of the fruit, and an aromatic acrid taste. Its sp. gr. is 0·946 according to Baumé, 0·931 according to Brande. Its constituents are carbon, hydrogen, and oxygen. It is much used to impart flavour to medicines, and to correct their nauseating and griping effects. The dose is from one to ten drops.

When oil of caraway is distilled with hydrated phosphoric acid, the distilled liquor being poured back into the retort until it ceases to have the smell of caraway, an oily liquid separates from the phosphoric acid, having a very disagreeable odour, and a strong taste. This product, to which the name of *carvacrol* has been applied, has been found to give immediate relief to toothache, when inserted on cotton into the cavity of a carious tooth. (See *Am. Journ. of Med. Sci.*, N. S. xv. 532.)

Off. Prep. Aqua Carui; Confectio Scammonii; Confectio Sennæ; Essentia Carui; Extractum Spigeliæ et Sennæ Fluidum; Pilulæ Aloës Compositæ; Pil. Rhei Compositæ; Spiritus Juniperi Compositus. W.

OLEUM CARYOPHYLLI. *U. S., Lond., Ed., Dub. Oil of Cloves.*

This oil is obtained by distilling cloves with water, to which it is customary to add common salt, in order to raise the temperature of ebullition; and the water should be repeatedly distilled from the same cloves, in order completely to exhaust them. Professor Scharling has found advantage from the application of super-heated steam to the distillation of this oil. (*Pharm. Journ. and Trans.*, xi. 469.) The product of good cloves is said to be about one-fifth or one-sixth of their weight. The oil was formerly brought from Holland or the East Indies; but, since the introduction of the Cayenne cloves into our markets, the reduced price and superior freshness of the drug have rendered the distillation of oil of cloves profitable in this country; and the best now sold is of domestic extraction. We have been informed that from seven to nine pounds of cloves yield to our distillers about one pound of the oil.

Properties. Oil of cloves, when recently distilled, is very fluid, clear, and colourless, but becomes yellowish by exposure, and ultimately reddish-brown. It has the odour of cloves, and a hot, acrid, aromatic taste. Its sp. gr. is variously stated at from 1·034 to 1·061, the latter being given by Bonastre as the sp. gr. of the rectified oil. It is one of the least volatile of the essential oils, and requires for congelation a temperature from zero of Fahrenheit to —4°. It is completely soluble in alcohol, ether, and strong acetic acid. Nitric acid changes its colour to a deep red, and converts it by the aid of heat into oxalic acid. When long kept it deposits a crystalline *stearoptene*. It is frequently adulterated with fixed oils, and sometimes also with oil of pimento and with copaiba. When pure it sinks in distilled water. According to Zeller, its character of congealing entirely into a crystalline mass with the alcoholic solution of potassa, losing at the same time its peculiar odour, affords a sufficient criterion of its purity.

According to Ettling, the oil of cloves consists of two distinct oils, one lighter, the other heavier than water. They may be obtained separate by distilling the oil from a solution of potassa. The lighter comes over, the heavier remains combined with the potassa, from which it may be separated by adding sulphuric acid, and again distilling. *Light oil of cloves* is colourless, has the sp. gr. 0·918, and consists exclusively of carbon and hydrogen, being isomeric with pure oil of turpentine. It is said not to possess active properties. (*Kane.*) *Heavy oil of cloves* is colourless at first, but darkens with age, has the odour and taste of cloves, is of the sp. gr. 1·079, boils at 470°, and forms soluble and crystallizable salts with the alkalies. Hence it has been called *eugenic* or *caryophyllic acid*. It consists of carbon, hydrogen, and oxygen; the formula, according to Ettling, being $C_{24}H_{15}O_5$.

Medical Properties and Uses. The medical effects of the oil are similar to those of cloves, and it is used for the same purposes; but its most common employment is as a corrigent of other medicines. Like other powerful irritants, it is sometimes effectual in relieving toothache, when introduced into the cavity of a carious tooth. The dose is from two to six drops.

Off. Prep. Confectio Aromatica; Confectio Scammonii; Pilulæ Colocynthidis Compositæ. W.

OLEUM CHENOPODII. *U. S. Oil of Wormseed.*

This oil is peculiar to the United States. The best is prepared in the vicinity of Baltimore. (See *page* 212.) It is of a light-yellow colour when recently distilled, but becomes deeper yellow, and even brownish by age. It has in a high degree the peculiar flavour of the plant. Its sp. gr. is 0·908. It is used as an anthelmintic, in the dose of from four to eight drops for a child, repeated morning and evening for three or four days, and then followed by a brisk cathartic. The case of a child, six years old, is recorded in the *Boston Med. and Surg.*

Journ. (xlv. 373), in which death is supposed to have resulted from the use of overdoses of this oil. W.

OLEUM COPAIBÆ. *U.S., Lond., Ed. Oil of Copaiba.*

"Take of Copaiba *two pounds;* Water *four gallons.* Add the Copaiba to the Water in a tinned still, and, having adapted a proper refrigeratory, distil three gallons. Separate the Oil which comes over from the water, return the latter to the Copaiba, and again distil three gallons. Lastly, separate the Oil obtained in the second distillation, add to it that first obtained, and keep the whole in a well stopped bottle." *U.S.*

"Take of Copaiva *one ounce;* Water *one pint and a half* [Imperial measure]. Distil, preserving the water; when most of the water has passed over, heat it, return it into the still, and resume the distillation; repeat this process so long as a sensible quantity of oil passes over with the water." *Ed.*

The oil constitutes from one-third to one-half or more of the copaiba. From one specimen of recent copaiba as much as 80 per cent. of oil has been obtained. (*Am. Journ. of Pharm.*, xxii. 289). It is prepared largely in Philadelphia by the application of steam heat. (See page 1096). As it first comes over it is colourless, but the latter product is of a fine greenish hue. By redistillation it may be rendered wholly colourless. It has the odour and taste of copaiba, boils at about 470° (*Christison*), is soluble in ether and alcohol, absorbs muriatic acid gas and forms with it crystals of artificial camphor, and when pure consists exclusively of carbon and hydrogen, being isomeric with pure oil of turpentine. In consequence of its want of oxygen, it answers even better than naphtha for preserving potassium, a fact first observed by Mr. Durand, of Philadelphia.

Its effects on the system are those of copaiba. From the experiments of C. Mitscherlich it is one of the least injurious to the animal system of the volatile oils; six drachms of it having been introduced into the stomach of a rabbit without causing death. Externally applied it produces much less irritation than the oil of turpentine. It may be given for the same purposes as copaiba in the dose of ten or fifteen drops; and may be administered in emulsion, or simply dropped on sugar. W.

OLEUM CUBEBÆ. *U.S., Ed., Dub. Oil of Cubebs.*

This oil is obtained from cubebs, by grinding them, and then distilling with water. From ten pounds Schönwald procured eleven ounces of oil, and this result very nearly coincides with the experiments of Christison, who obtained seven per cent. When perfectly pure, the oil is colourless; but as usually found, is yellowish or greenish. It has the smell of cubebs, and a warm, aromatic, camphorous taste; is of a consistence approaching that of almond oil; is lighter than water, having the sp. gr. 0·929; and, when exposed to the air, is said to thicken without losing its odour. Upon standing, it sometimes deposits crystals, which are thought to be a hydrate of the oil. It consists of carbon and hydrogen, and its formula is stated to be $C_{15}H_{12}$.

The oil has the medicinal properties of cubebs, but it is probably not the sole active ingredient; as it is much less pungent than the fluid extract or oleo-resin. It may, however, often be advantageously substituted for the powder, in the commencing dose of ten or twelve drops, to be gradually increased until its effects are obtained, or until it proves offensive to the stomach. It may be given suspended in water by means of sugar, or in the form of emulsion, or enclosed in capsules of gelatin. W.

OLEUM FŒNICULI. *U.S., Lond., Ed., Dub. Oil of Fennel.*

Fennel seeds yield about 2·5 per cent. of oil. That used in this country is imported. It is colourless or yellowish, with the odour and taste of the seeds. Its sp. gr. is 0·997. It congeals below 50° into a crystalline mass, separable by

pressure into a solid and liquid oil (*stearoptene* and *eleoptene*); the former heavier than water, and less volatile than the latter, which rises first when the oil is distilled. As found in the shops, therefore, the oil of fennel is not uniform; and Dr. Montgomery found that a specimen which he examined did not congeal at 22°. It consists of carbon, hydrogen, and oxygen; its formula being, according to Blanchet and Sill, $C_{13}H_8O_2$. The dose is from five to fifteen drops.

Off. Prep. Aqua Fœniculi; Confectio Piperis Nigri; Essentia Fœniculi; Extractum Rhei Fluidum; Extractum Sennæ Fluidum; Spiritus Juniperi Compositus. W.

OLEUM GAULTHERIÆ. *U. S.* *Oil of Partridge-berry.*

This oil is a product of the United States, and is prepared chiefly in New Jersey. It is directed by the Pharmacopœia to be prepared from the leaves of *Gaultheria procumbens;* but the whole plant is usually employed. It has been obtained by Prof. Procter from the bark of *Betula lenta* or sweet birch, and has been supposed to exist also in the root of *Polygala paucifolia*, and the roots and stems of *Spiræa ulmaria*, *Spiræa lobata*, and *Gaultheria hispidula*, which have its peculiar flavour.

Oil of partridge-berry when freshly distilled is nearly colourless, but as found in the shops has a brownish-yellow or reddish colour. It is of a sweetish, slightly pungent, peculiar taste, and a very agreeable characteristic odour, by which it may be readily distinguished from all other officinal oils. It is the heaviest of the known essential oils, having the sp. gr. 1·173. Its boiling point is 412°. (*Am. Journ. of Pharm.*, iii. 199, and xiv. 213.) Its unusual weight affords a convenient test of its purity. Prof. Procter proved it to possess acid properties, and to be closely analogous to *salicylous acid*, one of the results of the decomposition of salicin by sulphuric acid and bichromate of potassa, and an ingredient in the oil of *Spiræa ulmaria.* (See *Salix.*) By M. Cahours it has since been shown to have the same composition as the salicylate of methylene; and a product having its properties was obtained by distilling a mixture of pyroxylic spirit, salicylic acid, and sulphuric acid. (*Am. Journ. of Pharm.*, xiv. 211, and xv. 241.) Dr. T. J. Gallaher, of Pittsburg, Pa., records the case of a boy, nine years old, who took about half an ounce of this oil, with the effect of producing severe vomiting, purging, epigastric pain, hot skin, frequent pulse, slow and laboured respiration, dulness of hearing, and, notwithstanding excessive gastric irritability, an uncontrollable desire for food. After two or three days of great danger, he began to improve, and in two weeks was entirely restored to health. (*Med. Examiner*, N. S., viii. 347.) Oil of gaultheria is used chiefly, on account of its pleasant flavour, to cover the taste of other medicines.

Off. Prep. Syrupus Sarsaparillæ Compositus. W.

OLEUM HEDEOMÆ. *U. S.* *Oil of Pennyroyal.*

This, though analogous in properties to the oil of European pennyroyal, is derived from a distinct plant (*Hedeoma pulegioides*) peculiar to North America. It has a light-yellow colour, with the odour and taste of the herb. Its sp. gr. is 0·948. It may be used as a remedy in flatulent colic and sick stomach, to correct the operation of nauseating or griping medicines, and to impart flavour to mixtures. It is also much employed as a domestic remedy in amenorrhœa. The dose is from two to ten drops. W.

OLEUM JUNIPERI. *U.S.*, *Lond.*, *Ed.*, *Dub.* *Oil of Juniper.*

The proportion of oil which juniper berries afford is stated very differently by different authors. Trommsdorff obtained one per cent. The highest quantity given in the table of Recluz is 2·34, the lowest 0·31 per cent. The berries are most productive when bruised. The oil of juniper consumed in this country is brought from Europe, and is believed to be procured chiefly from the tops of

the plant, being sold for a price which is altogether incompatible with the idea that it is prepared from the fruit alone. It is colourless, or of a light greenish-yellow, with a terebinthinate odour, and a hot acrid taste. Its sp. gr. is 0 911. It is not very soluble in alcohol. According to Blanchet, it contains two isomeric oils, of which one is colourless, and the other coloured and less volatile. It is, when pure, a carbohydrogen, and is said to have the same composition as oil of turpentine ($C_{10}H_8$); but it does not form a solid compound with muriatic acid. (*Journ. de Pharm.*, xxvi. 80.) Oil of turpentine is often fraudulently added, but may be detected by the specific gravity of the mixture, which is considerably less than that of the unadulterated oil of juniper.

The oil is stimulant, carminative, and diuretic; and may be employed advantageously in debilitated dropsical cases, in connexion with other medicines, especially digitalis. It is this oil which imparts to Holland gin its peculiar flavour and diuretic power. The dose is from five to fifteen drops two or three times a day, and may be considerably increased.

Off. Prep. Spiritus Juniperi Compositus. W.

OLEUM LAVANDULÆ. *U. S., Lond., Ed., Dub. Oil of Lavender.*

This oil is usually distilled from the flowers and flower-stems conjointly, though of finer quality when obtained from the former exclusively. Dried lavender flowers yield from 1 to 1·5 per cent. of a very fluid, lemon-yellow oil, having the fragrance of the flowers, and an aromatic, burning taste. That met with in commerce has the sp. gr. 0·898 at 68° F., which is reduced to 0·877 by rectification. (*Berzelius.*) According to Brande, the sp. gr. of the oil obtained from the whole herb is 0·9206. Alcohol of 0·830 dissolves oil of lavender in all proportions; that of 0·877, only 42 per cent. (*Berzelius.*) Proust states that, when allowed to stand in imperfectly stopped bottles, it lets fall a crystalline deposit, which often amounts to one-fourth of its weight. It is said that the portion of oil first distilled is most agreeably fragrant, and is often kept separate, and sold at a higher price. Oil of lavender is used chiefly as a perfume, though possessed of carminative and stimulant properties, and sometimes useful in cases of nervous languor and headache. The dose is from one to five drops.

Oil of Spike is procured from the broad-leaved variety of lavender which grows wild in Europe, the *Lavandula Spica* of De Candolle. Its odour is less fragrant than that of common oil of lavender, and is somewhat analogous to that of oil of turpentine, with which it is said to be often adulterated. It is used by artists in the preparation of varnishes.

OLEUM MENTHÆ PIPERITÆ. *U.S, Lond., Ed., Dub. Oil of Peppermint.*

Peppermint varies exceedingly in the quantity of oil which it affords. Four pounds of the fresh herb yield, according to Baumé, from a drachm and a half to three drachms of the oil. The product is generally less than one per cent. This oil is largely distilled in the United States. It is of a greenish-yellow colour or nearly colourless, but becomes reddish by age. Its odour is strong and aromatic, its taste warm, camphorous, and very pungent, but succeeded, when air is admitted into the mouth, by a sense of coolness. Its sp. gr. is stated differently from 0·902 to 0·920; its boiling point at 365°. Upon long standing it deposits a *stearoptene*, which, according to Kane, has the same composition as the oil, viz., $C_{21}H_{20}O_2$. Berzelius states that at 8° below zero the oil deposits small capillary crystals. This oil is frequently adulterated with alcohol, and occasionally, there is reason to believe, with oil of turpentine. This is detected by its odour, by its

deficient solubility in cold alcohol, and by imparting the property of exploding with iodine.

Oil of peppermint is stimulating and carminative, and is much used in flatulence, nausea, spasmodic pains of the stomach and bowels, and as a corrigent or adjuvant of other medicines. The dose is from one to three drops, and is most conveniently given rubbed up with sugar and then dissolved in water. The oil is more frequently employed, dissolved in alcohol, in the form of *essence of peppermint*, which is now an officinal preparation. (See *Tinctura Olei Menthæ Piperitæ.*)

Off. Prep. Aqua Menthæ Piperitæ; Essentia Menthæ Piperitæ; Pilulæ Rhei Compositæ; Spiritus Menthæ Piperitæ; Tinctura Olei Menthæ Piperitæ; Trochisci Menthæ Piperitæ. W.

OLEUM MENTHÆ VIRIDIS. *U. S., Lond., Ed., Dub. Oil of Spearmint.*

According to Lewis, ten pounds of spearmint yield an ounce of oil; by others the product is stated not to exceed one part from five hundred. The oil is largely distilled in this country. It is pale-yellow or greenish when recently prepared, but becomes red with age, and ultimately almost of a mahogany colour. Its flavour is analogous to that of the oil of peppermint, but less agreeable and less pungent. Its sp. gr. is stated differently from 0·914 to 0·975; its boiling point at 320°. Kane gives the formula $C_{35}H_{28}O$, as representing its composition. It is used for the same purposes as the oil of peppermint, in the dose of from two to five drops. An *essence of spearmint*, prepared by dissolving the oil in alcohol, is now officinal. (See *Tinctura Olei Menthæ Viridis.*)

Off. Prep. Aqua Menthæ Viridis; Essentia Menthæ Viridis; Spiritus Menthæ Viridis; Tinctura Olei Menthæ Viridis. W.

OLEUM MONARDÆ. *U. S. Oil of Horsemint.*

This is prepared by our distillers from the fresh herb of *Monarda punctata*. It has a reddish-amber colour, a fragrant odour, and a warm, very pungent taste. At the temperature of 40° F. or lower, especially in the presence of moisture, it is gradually transformed by oxidation into a crystalline body, having the odour and taste of the oil. This appears to be analogous in constitution to camphor, being the oxide of a carbohydrogen radical ($C_{10}H_7$), three eqs. of which with one eq. of oxygen form the liquid oil. (C. T. Bonsall, *Am. Journ. of Pharm.*, xxv. 200.) Applied to the skin, monarda oil acts as a powerful rubefacient, quickly producing heat, pain, redness, and even vesication. This property of the oil was made known to the profession by Dr. Atlee, of Philadelphia, who employed it externally with advantage in low forms of typhus fever, cholera infantum, chronic rheumatism, and other affections in which rubefacients are indicated. In ordinary cases it should be diluted before being applied. It may be given internally as a stimulant and carminative, in the dose of two or three drops mixed with sugar and water. W.

OLEUM ORIGANI. *U. S., Ed. Oil of Origanum.*

This is obtained from the common marjoram, *Origanum vulgare*, and is frequently called *oil of marjoram*. The plant varies exceedingly in the proportion which it affords. The mean product may be stated at from four to six parts from a thousand. The recent oil, when properly prepared, is yellow; but if too much heat is used in the distillation, it is said to be reddish, and it acquires the same tint by age. It may be obtained colourless by rectification. It has the odour of the plant, and a hot acrid taste. Kane gives its sp. gr. 0·867, its boiling point 354°, and its composition $C_{50}H_{40}O$. According to Lewis its sp. gr. is 0·940, according to Brande 0·909. It is sometimes used as an external irritant, and to allay the pain of toothache, by being introduced, on lint or cotton, into the cavity

of a carious tooth. It is not employed internally. The oil commonly sold as oil of origanum has been ascertained by Mr. Daniel Hanbury to be the oil of thyme (*Thymus vulgaris*), and is prepared in the South of France. As it reaches this country it is generally largely adulterated with oil of turpentine.

It can scarcely be doubted that the oil directed by the Edinburgh College from *Origanum Majorana*, or *sweet marjoram*, was intended for that of *Origanum vulgare;* as the latter plant is indicated, under the name of *Origanum*, in the Materia Medica list of the College, where the former is not mentioned; and the oil is referred to in the Index of the Pharmacopœia with the title of Oleum Origani. The *oil of sweet marjoram* is obtained from the plant by distillation, in the quantity of from 2·5 to 6 parts from 1000. It is of a lemon-yellow colour, light, and camphorous, and is said upon long standing to deposit a substance resembling camphor. It is not used in this country.

Off. Prep. Linimentum Saponis Camphoratum. W.

OLEUM PIMENTÆ. *U. S., Lond., Ed., Dub. Oil of Pimento.*

The berries yield from 1 to more than 4 per cent. of oil, which, as found in the shops, has a brownish-red colour, and the odour and taste of pimento, though warmer and more pungent. It is said, when freshly distilled, to be colourless or yellowish. Nitric acid reddens it. Bonastre states that it combines with salifiable bases like the oil of cloves. Its sp. gr. has been stated at 1·021, but varies. It consists, like the oil of cloves, of two distinct oils, a lighter and heavier, the former of which comes over first in distillation. They may be separated by distilling the oil with caustic potassa. The light oil comes over, and the heavy remains combined with the potassa. The latter may be obtained by distilling the residue with sulphuric acid. The light oil is lighter than water, and is a pure carbohydrogen. The heavy has the acid property of forming crystalline compounds with the alkalies. They are analogous to the light and heavy oils of cloves. The oil of pimento is given for the same purposes with the other aromatic stimulant oils. The dose is from three to six drops.

Off. Prep. Aqua Pimentæ; Essentia Pimentæ. W.

OLEUM PULEGII. *Lond., Ed.* Oleum Menthæ Pulegii. *Dub. Oil of European Pennyroyal.*

About 1 part of this oil on an average is obtained from 100 parts of the plant. It is yellowish when freshly distilled, but becomes reddish by age. Its sp. gr. is stated differently from 0·925 to 0·978. It possesses medical properties similar to those of the oil of peppermint; but is seldom used in this country. The dose is from one to five drops.

Off. Prep. Aqua Pulegii; Essentia Menthæ Pulegii; Spiritus Pulegii. W.

OLEUM ROSMARINI. *U. S., Lond., Ed., Dub. Oil of Rosemary.*

The fresh leaves of rosemary yield, according to Baumé, 0·26 per cent. of oil; but the product is stated much higher by other authors. According to Brande, a pound of the fresh herb yields about a drachm of the oil, which is about one per cent. This oil is colourless, with an odour similar to that of the plant, though less agreeable. Its sp. gr. is 0·911, but is reduced to 0·8886 by rectification. It is soluble in all proportions in alcohol of 0·830; but requires for solution at 64°, forty parts of alcohol of the sp. gr. 0·887. (*Berzelius.*) Kane gives its sp. gr. 0·897, its boiling point 365°, and its composition $C_{45}H_{38}O_2$. Kept in bottles imperfectly stopped, it deposits a *stearoptene* analogous to camphor, and sometimes amounting, according to Proust, to one-tenth of the oil. Bucholz states that it affords camphor when digested with from one-half its weight to an equal weight of potassa, and distilled. It is said to be sometimes

adulterated with oil of turpentine, which may be detected by mixing the suspected liquid with an equal volume of pure alcohol. The oil of rosemary is dissolved, and that of turpentine left. This oil is possessed of stimulant properties, but is employed chiefly as an ingredient of rubefacient liniments. The dose is from three to six drops.

A case of death is recorded, in a child four or five years old, from a mixture of six measures of this oil, and two of oil of wormseed, given in repeated doses of a tablespoonful. (*Am. Journ. of Pharm.*, xxiii. 286.)

Off. Prep. Essentia Rosmarini; Linimentum Opii; Linimentum Saponis Camphoratum; Spiritus Ammoniæ Aromaticus; Spiritus Rosmarini; Tinctura Lavandulæ Composita; Tinctura Saponis Camphorata. W.

OLEUM RUTÆ. *Lond., Ed. Oil of Rue.*

Rue yields a very small proportion of a yellow or greenish oil, which becomes brown with age. It has the strong unpleasant odour of the plant, and an acrid taste. Kane gives its sp. gr. 0·837, its boiling point 446°, and its composition $C_{28}H_{28}O_3$. It is stimulant and antispasmodic, and has been given in hysteria, convulsions, and amenorrhœa. The dose is from two to five drops. W.

OLEUM SABINÆ. *U. S., Lond., Ed., Dub. Oil of Savine.*

According to the more recent authorities, the proportion of volatile oil obtained from savine varies from less than 1 to 2·5 per cent. The oil is nearly colourless or yellow, limpid, strongly odorous, and of a bitterish, extremely acrid taste. Kane gives its sp. gr. 0·915, its boiling point 315°, and its composition $C_{10}H_8$, equivalent to that of oil of turpentine. According to Winckler, it is converted by sulphuric acid into an oil not distinguishable from that of thyme. (*Chem. Gaz.*, Jan. 1847, p. 11.) The oil of savine is stimulant, emmenagogue, and actively rubefacient, and may be given for the same purposes as the plant in substance. It has been much employed empirically in amenorrhœa, and with a view to produce abortion, and in some instances with fatal effects. The dose is from two to five drops. W.

OLEUM SASSAFRAS. *U.S., Ed. Oil of Sassafras.*

The proportion of oil yielded by the root of sassafras is variously stated from less than 1 to somewhat more than 2 per cent. The bark of the root, directed by the U.S. Pharmacopœia, would afford a larger quantity. The oil is of a yellow colour, becoming reddish by age. It has the fragrant odour of sassafras, with a warm, pungent, aromatic taste. It is among the heaviest of the volatile oils, having the sp. gr. 1·094. According to Bonastre, it separates, by agitation with water, into two oils, one lighter, the other heavier than water. Berzelius states that the first is often nothing more than oil of turpentine existing as an adulteration in the oil of sassafras. Nitric acid colours it red, and fuming nitric acid inflames it more readily than most other oils. It has the property of dissolving caoutchouc. When kept for a long time it deposits transparent crystals, having the same odour as the liquid oil. By treating the oil with chlorine, neutralizing with lime, and distilling, a product is obtained identical in properties and composition with common camphor. (See *Am. Journ. of Pharm.*, xxvi. 166.) Oil of sassafras is stimulant, carminative, and supposed to be diaphoretic; and may be employed for the same purposes with the bark from which it is derived. The dose is from two to ten drops.

Off. Prep. Syrupus Sarsaparillæ Compositus. W.

OLEUM SUCCINI. *U.S., Dub. Oil of Amber.*

"Take of Amber, in powder, *any quantity*. Put the Amber, previously mixed with an equal weight of sand, into a glass retort, which is to be only half filled; then distil, by means of a sand-bath, with a gradually increasing heat, an acid

liquor, an oil, and a concrete acid impregnated with oil. Separate the Oil from the other matters, and keep it in well stopped bottles." *U. S.*

The *Dublin College* has transferred the oil of amber from the preparations to the Materia Medica list.

The amber in this process undergoes decomposition, and affords, among other products, an empyreumatic oil, which floats in the receiver upon the surface of an acid liquor. The heat requisite for the complete decomposition of the amber cannot be supported by a glass retort; and, in order that all the oil which it is capable of yielding may be collected, the distillation should be performed in a tubulated iron or earthenware retort, which may be placed immediately upon the fire. The sand is added to prevent the amber from swelling too much. The oil may be separated from the acid liquor by means of the separating funnel. As first procured, it is a thick, very dark-coloured liquid, of a peculiar strong empyreumatic odour. In this state it is occasionally employed as a liniment; but for internal use it should be rectified. It is said that the scrapings of *copal* and the resin *dammar* are often substituted for amber, and yield an oil scarcely distinguishable from the genuine. (*Pereira's Mat. Med.*)

Off. Prep. Oleum Succini Rectificatum. W.

OLEUM SUCCINI RECTIFICATUM. *U. S. Rectified Oil of Amber.*

"Take of Oil of Amber *a pint;* Water *six pints.* Mix them in a glass retort, and distil until four pints of the Water shall have passed with the oil into the receiver; then separate the Oil from the Water, and keep it in well stopped bottles." *U. S.*

By successive distillations the oil of amber is rendered thinner and more limpid, till at length it is obtained colourless. The first portions which distil are less coloured than those which follow, and may be separated for keeping, while the remainder is submitted to another distillation. For practical purposes, however, the oil is sufficiently pure when once redistilled, as directed in the U. S. Pharmacopœia. As usually found in the shops, the rectified oil is of a light yellowish-brown or amber colour. When quite pure it is colourless, as fluid as alcohol, of the sp. gr. 0·758 at 75°, and boils at 186°. It has a strong, peculiar, unpleasant odour, and a hot, acrid taste. It imparts these properties in some degree to water without being perceptibly dissolved. It is soluble in eight parts of alcohol of the sp. gr. 0·847 at 55°, in five parts of the sp. gr. 0·825, and in all proportions in absolute alcohol. The fixed oils unite with it. On exposure to the light and air, it slowly changes in colour and consistence, becoming ultimately black and solid. It appears, when quite pure, to be a carbohydrogen, consisting, according to Dr. Döpping, of 88·46 parts of carbon and 11·54 of hydrogen in 100 parts. (*Chem. Gaz.*, Nov. 1845, p. 447.) It is said to be sometimes adulterated with oil of turpentine, which may be detected by passing muriatic acid gas through the suspected oil. If pure it will remain wholly liquid; while oil of turpentine if present will give rise to the formation of solid artificial camphor. (*Pharm. Journ. and Trans.*, 13, 292.)

Medical Properties and Uses. Rectified oil of amber is stimulant and antispasmodic, and occasionally promotes the secretions, particularly that of urine. It has been employed with advantage in amenorrhœa, and in various spasmodic and convulsive affections, as tetanus, epilepsy, hysteria, hooping-cough, and infantile convulsions from intestinal irritation, &c. The dose is from five to fifteen drops, diffused in some aromatic water by means of sugar and gum Arabic. Externally applied the oil is rubefacient, and is considerably employed as a liniment in chronic rheumatism and palsy, and in certain spasmodic disorders, as hooping-cough and infantile convulsions. In the latter affection it should be

rubbed along the spine, and was highly recommended by the late Dr. Joseph Parrish, mixed with an equal measure of laudanum, and diluted with three or four parts of olive oil and of brandy. W.

OLEUM TABACI. *U.S.* *Oil of Tobacco.*

"Take of Tobacco, in coarse powder, *a pound.* Put the Tobacco into a retort of green glass, connected with a refrigeratory, to which a tube is attached for the escape of the incondensible products; then, by means of a sand-bath, heat the retort gradually to dull redness, and maintain that temperature until empyreumatic oil ceases to come over. Lastly, separate the dark oily liquid in the receiver from the watery portion, and keep it for use." *U.S.*

This is a black, thickish liquid, of a strong characteristic odour, identical with that of old tobacco pipes, and in no degree resembling that of undecomposed tobacco. It may be obtained colourless by rectification, but soon becomes yellowish, and ultimately brown. It probably contains a portion of nicotia volatilized unchanged, and is a powerful poison, unfit for internal use, and when employed externally requiring much caution. Mixed with simple ointment or lard in the proportion of twenty drops to an ounce, it has been used as an application to indolent tumours, buboes, ulcers, and obstinate cutaneous eruptions; but in all cases where the cuticle is wanting, it should be employed with reserve, and carefully watched. W.

OLEUM TEREBINTHINÆ PURIFICATUM. *Ed.* *Purified Oil of Turpentine.*

"Take of Oil of Turpentine *one pint;* Water *four pints.* Distil as long as Oil comes over with the Water." *Ed.*

Oil of turpentine becomes impure by exposure, in consequence of the absorption of oxygen and the production of resin. From this it may be freed by distillation, as above directed, or by the agency of alcohol. (See *Oleum Terebinthinæ.*) The process for distilling it is attended with some danger, in consequence of the great inflammability of the vapour, and its rapid formation, which causes the liquor to boil over. In this country, the apothecary can almost always purchase the oil sufficiently pure for medical use without the necessity of rectifying it. The presence of a little resin does not interfere with its efficiency as a medicine. W.

OLEUM VALERIANÆ. *U.S.* *Oil of Valerian.*

This was introduced for the first time as an officinal into the U. S. Pharmacopœia of 1850. It is obtained from the root of Valeriana officinalis by the usual process of distillation with water. Very good oil has been distilled from the root cultivated in this country. As first procured, it is of a pale-greenish colour, of the sp. gr. 0·934, with a pungent odour of valerian, and an aromatic taste. Upon exposure, it becomes yellow and viscid. It is a complex substance, containing 1. a carbohydrogen isomeric with pure oil of turpentine, 2. a small proportion of stearoptene of an odour resembling that of camphor and pepper, and formed probably by the combination of water with the preceding constituent, 3. a peculiar oxygenated oil, called *valerol* ($C_{20}H_{12}O$, Kane's *Chemistry*), which by the agency of the air is converted into *valerianic* (*valeric*) *acid* and a resinous matter; and 4. valerianic acid, which always exists in the oil in small proportion, but is increased by exposure. The conversion of valerol into valerianic acid through the agency of atmospheric oxygen is very much promoted by the presence of caustic alkalies, which combine with the acid when formed, to produce valerianates. The oil of valerian exercises the influence of the root upon the nervous system, and is frequently administered as a substitute for it in the dose of four or five drops. W.

PILULÆ.

Pills.

These are small globular masses of a size convenient for swallowing. They are well adapted for the administration of medicines which are unpleasant to the taste or smell, or insoluble in water, and do not require to be given in large doses. Deliquescent substances should not be made into pills; and those which are effloresceut should be previously deprived of their water of crystallization. Care should also be taken not to combine materials, the mutual reaction of which may result in a change of form.

Some substances have a consistence which enables them to be made immediately into pills. Such are the softer extracts and certain gum-resins; and the addition of a little water to the former, and a few drops of spirit to the latter, will give them the requisite softness and plasticity, if previously wanting. Substances which are very soft, or in the liquid state, are formed into the pilular mass by incorporation with dry and inert powders, such as crumb of bread, wheat flour, starch, and powdered gum Arabic. Powders must be mixed with soft, solid bodies, as extracts, confections, soap, &c., or with tenacious liquids, as syrup, molasses, honey, or mucilage. Heavy metallic powders are most conveniently made into pills with the former; light vegetable powders with the latter. Mucilage is very often used; but pills made with it are apt when kept to become hard, and of difficult solubility in the liquors of the stomach, and if metallic substances are mixed with it, the mass does not work well. A mixture of syrup and powdered gum Arabic is not subject to the same inconveniences, and is an excellent material for the formation of pills. Conserve of roses and molasses are among the best excipients, when the pills are to be long kept. For the same purpose of keeping the pill soft, a small portion of some fixed oil or deliquescent salt has been recommended as an addition to the mass. Many powders require only the addition of water. Such are all those which contain ingredients capable of forming an adhesive or viscid solution with that liquid. Care should always be taken that the matter added be not incompatible with the main ingredients of the pill.

The materials should be accurately mixed together, and beat in a mortar till formed into a perfectly uniform and plastic mass. This should be of such a consistence that the pills may preserve their form, without being so hard as to resist the solvent power of the gastric liquors. As pills often become very hard by time, it is often convenient to keep the mass in a state fit to be divided when wanted for use. This may be done by wrapping it in bladders, putting it in covered pots, and occasionally moistening it as it becomes dry; or more effectually by keeping it in glass or well glazed jars, accurately closed with varnished bladder.

The mass, having been duly prepared, is made into pills by rolling it with a spatula into a cylinder of precisely the same thickness throughout, and of a length corresponding to the number of pills required. It is then divided as equally as possible by the hand, or more accurately by a machine made for the purpose.* The pills receive a spherical form by being rolled between the fingers. M. Mialhe describes a little instrument for rolling pills, composed of two circular plates, one about 12, the other 6 inches in diameter, the former having a ledge at the border one-third of an inch high, the latter with a similar ledge varying

* The common pill-machine is too well known to require description. In the *Am. Journ. of Pharm.* (xxiv. 315) the reader will find the description of a rotary pill-machine, calculated to prepare large numbers of pills in a short time: and in the same journal (xxvi. 118) another, which is considered to be an improvement on the first.

according to the size of the pills from less than a line to nearly two lines, and with a strap on the back by which it can be fitted to the hand. This is to be moved in a rotary manner upon the larger plate holding the divided portions of the pill mass. (*Journ. de Pharm. et de Chim.*, xvii. 218.) In order to prevent the adhesion of pills to one another, or to the sides of the vessel in which they may be placed, it is customary to agitate them with some dry powder, which gives them an external coating, that serves also to conceal their taste. For this purpose, carbonate of magnesia, starch, or powdered liquorice root may be used. Carbonate of magnesia is sometimes incompatible with one of the ingredients of the pills; and liquorice root will, as a general rule, be found the best. The powder of *lycopodium* is much employed on the continent of Europe; and it was formerly the custom to give the pill a coating of gold or silver leaf.

It has been proposed by M. Garot to cover pills with gelatin, which answers the purpose of concealing their taste and odour, and counteracting deliquescence or chemical change from exposure to the air, without interfering with their solubility in the stomach. He dips each pill, sustained on the point of a pin, into melted gelatin, withdraws it with a rotary motion, then fixes the pin in a paste so as to allow the coating to dry in the air, and, having prepared about fifty pills in this way, proceeds to complete the operation by holding the pin in the flame of a taper so as to melt the gelatin near its point, and then withdrawing it from the pill so as to close up the orifice. The purest glue should be selected for this purpose, melted with the addition of two or three drachms of water to an ounce of the glue, and kept liquid by means of a salt-bath.

Another plan of attaining the same objects, less effectual, but more convenient than the above, is to introduce the pills into a spherical box, to drop on them enough syrup simply to moisten their surface, then to give a rotary movement to the box until the pills are uniformly covered, and finally to add by degrees a powder consisting of equal parts of gum, sugar, and starch, shaking the box with each addition, and continuing the process until nothing more will adhere to the pills. The investing material may be rendered agreeable to the taste and smell by aromatic additions, if deemed advisable. (*Journ. de Pharm. et de Chim.*, x. 32.) M. Calloud finds that a better powder for the purpose, because less disposed to attract moisture, is made by boiling one part of flaxseed and three parts of white sugar with sufficient water till a thick mucilage is formed, evaporating this carefully to dryness, and then pulverizing. (*Ibid.*, xxiii. 301.)

Still another method, proposed by Mr. E. K. Durden, is to cover the pill with a coating of collodion, which completely conceals the taste. The solution employed by Mr. Durden had the sp. gr. of 0·810; and two dippings gave a sufficient coating. (See *Am. Journ. of Pharm.*, xxi. 183.) It is, however, yet to be determined whether a coating of collodion would yield readily to the solvent powers of the gastric juice.

Pills which are to be long kept should be well dried, and put into bottles with accurately fitting stoppers. If it is desirable that they should be kept soft, the better plan is to preserve them in mass as above recommended.

Though the U. S. Pharmacopœia, in almost every instance, orders the mass to be divided into pills; yet it should be understood rather as indicating the number of pills to be made from a certain quantity of the mass when particular directions are not given by the physician, than as requiring the division to be made immediately after the materials have been mixed. It will be found convenient by the apothecary to keep a portion of the mass undivided. W.

PILULÆ ALOËS. *U. S.*, *Ed.* PILULA ALOËS CUM SAPONE. *Lond.* *Aloetic Pills.* *Pill of Aloes with Soap.*

"Take of Aloes, in powder, Soap, each, *an ounce*. Beat them with water so as to form a mass, to be divided into two hundred and forty pills." *U. S.*

The *London College* takes *equal parts* of extract of Barbadoes aloes, soft soap, and liquorice (extract), and *a sufficiency* of molasses, beats the aloes with the soap, then adds the other ingredients, and beats the whole together.

The *Edinburgh College* directs *equal quantities* of Socotrine or East India aloes and Castile soap to be beat with conserve of red roses into a mass fit for forming pills.

The soap, in this formula, not only serves to impart a proper consistence to the aloes, but is thought to qualify its operation, and diminish its liability to irritate the rectum. Five of the U. S. pills, containing ten grains of aloes, may be given with a view to their purgative effect; but the preparation is usually employed as a laxative in habitual costiveness, in the quantity of one, two, or three pills, taken before breakfast or dinner, or at bedtime. W.

PILULÆ ALOËS COMPOSITÆ. *Dub.* PILULA ALOËS COMPOSITA. *Lond. Compound Pills of Aloes.*

"Take of Aloes, in powder, *an ounce;* Extract of Gentian *half an ounce;* Oil of Caraway *forty minims;* Molasses *a sufficient quantity.* Beat them together, so that they may be intimately mixed in a mass fit for forming pills." *Lond.*

The *Dublin College* directs *two ounces* [avoirdupois] of hepatic aloes, *an ounce* [avoird.] of extract of gentian, *a fluidrachm* of oil of caraway, and *an ounce* [avoird.] of molasses.

A reaction takes place between the aloes and extract of gentian when rubbed together, which renders the mass so soft as sometimes to require the addition of a light powder. This combination is well adapted as a laxative to the costiveness of sedentary and dyspeptic persons. The dose is from five to twenty grains, according to the degree of effect desired.* W.

PILULÆ ALOËS ET ASSAFŒTIDÆ. *U. S., Ed. Pills of Aloes and Assafetida.*

"Take of Aloes, in powder, Assafetida, Soap, each, *half an ounce.* Beat them with water so as to form a mass, to be divided into one hundred and eighty pills." *U. S.*

The *Edinburgh College* takes equal parts of Socotrine or East India aloes, assafetida, and Castile soap, and beats them into a mass with conserve of red roses.

These pills are peculiarly adapted, by the stimulant and carminative properties of the assafetida, to cases of costiveness attended with flatulence and debility of the digestive organs. Each pill contains about four grains of the mass. From two to five may be given for a dose. W.

* The following is the formula for the aloetic pills usually called *dinner pills, or Lady Webster's pills.* They are the *pilulæ stomachicæ* of the fifth edition of the Paris Codex, A. D. 1758. Take of the best Aloes six drachms; Mastich and Red Roses, each, two drachms; Syrup of Wormwood sufficient to form a mass, to be divided into pills of three grains each. Common syrup may be substituted for the syrup of wormwood. One or two of these pills, taken shortly before a meal, will usually produce one free evacuation.

The Philadelphia College of Pharmacy has adopted the following formulæ for the compound aloetic preparations commonly called *Hooper's* and *Anderson's pills.*

"*Hooper's female pills.* ℞. Aloës Barbadensis ℥viij., Ferri Sulphatis Exsiccati ʒij., ʒiss., *vel* Ferri Sulphatis Crystal. ℥iv., Extracti Hellebori ʒij., Myrrhæ ʒij., Saponis ʒij., Canellæ in pulv. tritæ ʒj., Zingiberis in pulv. trit. ʒj. —Beat them well together into a mass with water, and divide into pills, each containing two and a half grains." (*Journ. of the Phil. Col. of Pharm.*, v. 25.)

"*Anderson's Scots' pills.* ℞. Aloës Barbadensis ʒxxiv., Saponis ℥iv., Colocynthidis ʒj., Gambogiæ ʒj., Olei Anisi f ʒss. Let the aloes, colocynth, and gamboge be reduced to a very fine powder; then beat them and the soap with water into a mass, of a proper consistence to divide into pills, each containing three grains." *Ibid.*

PILULÆ ALOËS ET FERRI. *Ed. Pills of Aloes and Iron.*

"Take of Sulphate of Iron *three parts;* Barbadoes Aloes *two parts;* Aromatic Powder *six parts;* Conserve of Red Roses *eight parts.* Pulverize the Aloes and Sulphate of Iron separately; mix the whole ingredients; and beat them into a proper mass; which is to be divided into five-grain pills." *Ed.*

It is said that the laxative power of aloes is increased, and its tendency to irritate the rectum diminished, by combination with the sulphate of iron. (*Christison's Dispensatory.*) This combination is useful in constipation with debility of stomach, especially when attended with amenorrhœa. The dose is from one to three pills. W.

PILULÆ ALOËS ET MYRRHÆ. *U. S., Ed.* PILULA ALOËS CUM MYRRHÂ. *Lond.* PILULÆ ALOËS CUM MYRRHÂ. *Dub. Pills of Aloes and Myrrh.*

"Take of Aloes, in powder, *two ounces;* Myrrh, in powder, *an ounce;* Saffron *half an ounce;* Syrup *a sufficient quantity.* Beat the whole together so as to form a mass, to be divided into four hundred and eighty pills." *U. S.*

The *London College* takes *half an ounce* of Socotrine or hepatic aloes, *two drachms,* each, of saffron, myrrh, and soft soap, and *a sufficiency* of molasses, and beats them together; the *Edinburgh* takes *four parts* of Socotrine or East India aloes, *two parts* of myrrh, and *one part* of saffron, and beats them with conserve of red roses; the *Dublin* takes *two ounces* of hepatic aloes, *an ounce* of myrrh, *half an ounce* of saffron, and *two ounces and a half* of molasses; rubs the first three ingredients together and sifts them; then adds the treacle, and beats the whole into a uniform mass.

This composition has been long in use, under the name of *Rufus's pills.* It is employed as a warm stimulant cathartic in general debility attended with constipation, and retention or suppression of the menses. From three to six pills, or from ten to twenty grains of the mass may be given for a dose. W.

PILULÆ ASSAFŒTIDÆ. *U. S. Assafetida Pills.*

"Take of Assafetida *an ounce and a half;* Soap *half an ounce.* Beat them with water so as to form a mass, to be divided into two hundred and forty pills." *U. S.*

Each of these pills contains three grains of the gum-resin. They are a convenient form for administering assafetida, the unpleasant odour and taste of which render it very offensive in the liquid state. W.

PILULÆ CALOMELANOS COMPOSITÆ. *Ed., Dub.* PILULA HYDRARGYRI CHLORIDI COMPOSITA. *Lond. Compound Calomel Pills. Compound Pill of Chloride of Mercury.*

"Take of Chloride of Mercury [calomel], Oxysulphuret of Antimony, each, *two drachms;* Guaiacum [resin], in powder, Molasses, each, *half an ounce.* Rub the Chloride with the Oxysulphuret, then with the Guaiacum and Molasses, so as to form a mass." *Lond.*

The *Edinburgh College* takes of calomel and golden sulphuret of antimony, each, *one part;* guaiac, in fine powder, and treacle, each, *two parts;* mixes the solids in fine powder, then the treacle, and beats the whole into a mass, to be divided into six-grain pills. The *Dublin College* agrees with the London, employing about half the quantity of the active ingredients, and *a fluidrachm* of castor oil instead of the molasses.

We prefer the title "compound calomel pills" of the Edinburgh and Dublin Pharmacopœias; as, though not scientific, it is not, like the London name, liable to be confounded with that of corrosive sublimate. The antimonial employed by the Colleges is the same, though under different names, and is identical with

the U. S. precipitated sulphuret. According to Vogel, a reaction takes place between the calomel and sulphuret of antimony, resulting in the production of chloride of antimony and sulphuret of mercury. (*Annal. der Pharm.*, xxviii. 236.) The preparation was originally introduced to the notice of the profession by Dr. Plummer, who found it useful as an alterative, and upon whose authority it was at one time much employed under the name of *Plummer's pills.* The combination is well adapted to the treatment of chronic rheumatism, and of scaly and other eruptive diseases of the skin, especially when accompanied with a syphilitic taint. Four grains of the mass contain about one grain of calomel. From three to six grains or more may be given morning and evening. W.

PILULÆ CALOMELANOS ET OPII. *Ed. Pills of Calomel and Opium.*

"Take of Calomel *three parts;* Opium *one part;* Conserve of Red Roses *a sufficiency.* Beat them into a proper mass, which is to be divided into pills, each containing two grains of Calomel." *Ed.*

The proportion in which opium is united with calomel to meet different indications is so various, that such a combination as the above is scarcely a proper subject for officinal direction. W.

PILULA CAMBOGIÆ COMPOSITA. *Lond.* PILULÆ CAMBOGIÆ. *Ed. Compound Pill of Gamboge.*

"Take of Gamboge, in powder, *two drachms;* Socotrine or Hepatic Aloes, in powder, *three drachms;* Ginger, in powder, *a drachm;* Soft Soap *half an ounce.* Mix the powders together; then add the Soap, and beat the whole together so as to form a mass." *Lond.*

The *Edinburgh College* takes of gamboge, East India or Barbadoes aloes, and aromatic powder, each, *one part,* and of Castile soap *two parts;* pulverizes the gamboge and aloes separately, mixes all the powders, adds the soap, and then a sufficiency of syrup; and beats the whole into a proper pill mass.

This is an active purgative pill, and may be given in the dose of ten or fifteen grains. The formula is that of Dr. George Fordyce simplified. W.

PILULÆ CATHARTICÆ COMPOSITÆ. *U.S. Compound Cathartic Pills.*

"Take of Compound Extract of Colocynth, in powder, *half an ounce;* Extract of Jalap, Mild Chloride of Mercury [calomel], each *three drachms;* Gamboge, in powder, *two scruples.* Mix them together; then with water form a mass, to be divided into one hundred and eighty pills." *U. S.*

This cathartic compound was first made officinal in the second edition of the U. S. Pharmacopœia. It was intended to combine smallness of bulk with efficiency and comparative mildness of purgative action, and a peculiar tendency to the biliary organs. Such an officinal preparation was much wanted in this country, in which bilious fevers, and other complaints attended with congestion of the liver and portal circle generally, so much abound. The object of smallness of bulk is accomplished by employing extracts and the more energetic cathartics; that of a peculiar tendency to the liver, by the use of calomel; and that of efficiency with mildness of operation, by the union of several powerful purgatives. It is a fact, abundantly proved by experience, that drastic cathartics become milder by combination, without losing any of their purgative power. Nor is it difficult, in this case, to reconcile the result of observation with physiological principles. Cathartic medicines act on different parts of the alimentary canal and organs secreting into it. In small doses, both the irritation which they occasion and their purgative effect are proportionably lessened. If several are administered at the same time, each in a diminished dose, it is obvious that

the combined purgative effect of all will be experienced; while the irritation, being feeble in each part affected, and diffused over a large space, will be less sensible to the patient, and will more readily subside. In the compound cathartic pills, most of the active purgatives in common use are associated together in proportions corresponding with their respective doses, so that an excess of any one ingredient is guarded against, and violent irritation from this cause prevented. The name of the preparation may at first sight seem objectionable, as it might be applied to any compound pills possessing cathartic properties; but, when it is considered that the ingredients cannot all be expressed in the title, that no one is sufficiently prominent to give a designation to the whole, and that the preparation is intended as the representative of numerous cathartics, and calculated for a wide range of application, the name will not be considered an inexcusable deviation from ordinary medical nomenclature. It is highly important, for the efficiency of these pills, that they be prepared in exact compliance with the directions, and that the *compound extract of colocynth* and the *extract of jalap* used be of good quality. When they fail, the result is generally ascribable to the substitution of jalap for the extract, or to the use of a compound extract of colocynth made with nearly inert scammony, inferior aloes, and insufficient colocynth, and altogether badly prepared.

Three of the pills, containing 10⅔ grains of the mass, are a medium dose for an adult. In this quantity are four grains of compound extract of colocynth, three of extract of jalap, three of calomel, and two-thirds of a grain of gamboge. A single pill will generally be found to operate as a mild laxative. In a full dose, the preparation acts vigorously on the bowels, producing bilious stools, generally without much pain or disorder of the stomach. It may be employed in most instances where a brisk cathartic is required; but is particularly applicable to the early stages of bilious fevers, to hepatitis, jaundice, and all those derangements of the alimentary canal, or of the general health, which depend on congestion of the portal circle. W.

PILULA COLOCYNTHIDIS COMPOSITA. *Lond.* PILULÆ COLOCYNTHIDIS. *Ed.* PILULÆ COLOCYNTHIDIS COMPOSITÆ. *Dub. Compound Pill of Colocynth.*

"Take of Extract of Colocynth *a drachm;* Extract of Aloes, in powder, *six drachms;* Scammony, in powder, *two drachms;* Cardamom, in powder, *half a drachm;* Soft Soap *a drachm and a half.* Mix the powders together; then add the other ingredients, and beat all together so as to form a mass." *Lond.*

"Take of Socotrine or East India Aloes, and Scammony, of each, *eight parts;* Colocynth *four parts;* Sulphate of Potash and Oil of Cloves, of each, *one part;* Rectified Spirit *a sufficiency.* Pulverize the Aloes, Scammony, and Sulphate of Potash together; mix with them the Colocynth previously reduced to fine powder; add the Oil of Cloves; and with the aid of a small quantity of Rectified Spirit beat the whole into a proper pill mass; which is to be divided into five-grain pills." *Ed.*

"Take of Pulp of Colocynth, in fine powder, *one ounce* [avoirdupois]; Hepatic Aloes, in fine powder, *two ounces* [avoird.]; Scammony, in fine powder, Castile Soap, of each, *one ounce* [avoird.]; Oil of Cloves *one fluidrachm;* Treacle [molasses] *ten drachms* [Dub. weight.]. Reduce the Soap to a fine powder, and mix it with the Colocynth, Aloes, and Scammony; then rub all together with the Oil of Cloves and Treacle, and beat them into a mass of a uniform consistence." *Dub.*

The London preparation is only another form of the *compound extract of colocynth*, for which it was intended as a substitute; the ingredients, the proportions, and the dose being essentially the same. (See *Extractum Colocynthidis Com-*

positum.) The Edinburgh and Dublin preparations are imitations, differing in the proportions of their ingredients, and in containing colocynth in substance instead of the extract of colocynth. The sulphate of potassa is used by the Edinburgh College to promote the more complete division of the aloes and scammony; the rectified spirit, because it is believed to be retained by the mass more firmly than water, and thus to preserve the due consistence longer. The preparation is actively cathartic in the dose of from five to twenty grains.*

Off. Prep. Pilulæ Colocynthidis et Hyoscyami. W.

PILULÆ COLOCYNTHIDIS ET HYOSCYAMI. *Ed. Pills of Colocynth and Henbane.*

"Take of the Colocynth-pill mass *two parts;* Extract of Hyoscyamus *one part.* Beat them well together, adding a few drops of rectified spirit if necessary; and divide the mass into five-grain pills." *Ed.*

It is asserted that the compound pill and compound extract of colocynth are almost entirely deprived of their griping tendency by combination, as above, with the extract of hyoscyamus, without losing any of their purgative power. The dose is from five to twenty grains. W.

PILULA CONII COMPOSITA. *Lond. Compound Pill of Hemlock.*

"Take of Extract of Hemlock *five drachms;* Ipecacuanha, in powder, *a drachm;* Molasses *a sufficient quantity.* Beat them together so as to form a mass." *Lond.*

An anodyne and expectorant combination, useful in chronic bronchial diseases. The dose is five grains three times a day. W.

PILULÆ COPAIBÆ. *U. S. Pills of Copaiba.*

"Take of Copaiba *two ounces;* Magnesia, recently prepared, *a drachm.* Mix them, and set the mixture aside till it concretes into a pilular mass, which is to be divided into two hundred pills." *U. S.*

When copaiba is mixed with pure magnesia, it gradually loses its fluidity, forming at first a soft tenacious mass, and ultimately becoming dry, hard, and brittle. The quantity of magnesia, and the length of time requisite for this change, vary with the condition of the copaiba; being greater in proportion to the fluidity of this substance, or, in other words, to its amount of volatile oil. The quantity of magnesia directed by the Pharmacopœia, one-sixteenth of the weight of the copaiba, is sufficient to solidify the latter, as it is often found in the shops, in the course of six or eight hours; but, when the copaiba is fresh, or has been kept in closely stopped bottles, and retains, therefore, nearly the whole of its oil, it is necessary either to augment the proportion of magnesia, or to expose the mixture for a much longer time, or to diminish the volatile oil of the copaiba by evaporation. The magnesia combines chemically with the copaivic acid or hard resin, but, in relation to the volatile oil, acts merely as an absorbent; for, when the solidified mass is submitted to the action of boiling alcohol, a part is dissolved, abandoning the magnesia with which it was mixed, while the resin combined with another portion of the earth remains undissolved. Varieties of copaiba, therefore, are solidifiable by magnesia, directly in proportion to the hard resin they contain, and inversely in proportion to the volatile oil; the soft resin being indifferent. According to Guibourt, copaiba not solidifiable by mag-

* For some observations relative to the present simple extract of colocynth of the London College, employed in making these pills, showing that there has probably been an error in the last edition of the Pharmacopœia in reference to this extract, and suggesting the course which, under these circumstances, it would be safest for the apothecary to pursue, see *Extractum Colocynthidis*, p. 974.—*Note to the tenth edition.*

nesia, may be made so by adding one-sixth of Bordeaux or common European turpentine. (*Journ. de Pharm.*, xxv. 499.) The magnesia employed should not have been allowed to become hydrated by exposure to a moist air or otherwise. (*Ibid.*, 3*e sér.*, v. 475.) In the preparation of the pills of copaiba, care should be taken to divide the mass before it has become too hard. The advantage of this preparation is, that the copaiba is brought to the state of pill with little increase of bulk. Each pill contains nearly five grains of copaiba, and from two to six may be taken for a dose twice or three times a day.

Hydrate of lime produces the same effect as magnesia, and, as stated by M. Thierry, in a shorter time, if employed according to his formula. He takes 15 parts of copaiba and 1 part of slaked lime, mixes them in a marble mortar, transfers the mixture to an open vessel, places this upon a sand-bath, and sustains the heat for four hours, occasionally stirring. The hydrate of lime must have been freshly prepared from recently burnt lime. The mixture loses only a twenty-fourth of its weight, which is chiefly the water of the hydrate. (*Journ. de Pharm.*, 3*e sér.*, i. 310.) W.

PILULÆ CUPRI AMMONIATI. *Ed.* *Pills of Ammoniated Copper.*

"Take of Ammoniated Copper, in fine powder, *one part;* Bread-crumb *six parts;* Solution of Carbonate of Ammonia *a sufficiency.* Beat them into a proper mass, and divide it into pills, containing each half a grain of ammoniated copper." *Ed.*

This is a convenient form for administering ammoniated copper. One pill may be given night and morning, and the dose gradually increased to five or six pills. W.

PILULÆ DIGITALIS ET SCILLÆ. *Ed.* *Pills of Digitalis and Squill.*

"Take of Digitalis and Squill, of each, *one part;* Aromatic Electuary *two parts.* Beat them into a proper mass with Conserve of Red Roses; and divide the mass into four-grain pills." *Ed.*

These pills combine the diuretic properties of digitalis and squill, and may be given in dropsy. One or two pills constitute a dose. W.

PILULÆ FERRI CARBONATIS. *U. S.*, *Ed.* *Pills of Carbonate of Iron. Vallet's Ferruginous Pills.*

"Take of Sulphate of Iron *eight ounces;* Carbonate of Soda *ten ounces;* Clarified Honey *three ounces;* Sugar, in powder, *two ounces;* Boiling Water *two pints;* Syrup *a sufficient quantity.* Dissolve the Sulphate of Iron and Carbonate of Soda, each, in a pint of the Water, a fluidounce of Syrup having been previously added to each pint; then mix the two solutions, when cold, in a bottle just large enough to hold them, close it accurately with a stopper, and set it by that the carbonate of iron may subside. Pour off the supernatant liquid, and, having washed the precipitate with water sweetened with Syrup, in the proportion of a fluidounce of the latter to a pint of the former, until the washings no longer have a saline taste, place it upon a flannel cloth to drain, and afterwards express as much of the water as possible; then immediately mix the precipitate with the Honey and Sugar, and by means of a water-bath evaporate the mixture, constantly stirring, until it is so far concentrated as to have a pilular consistence on cooling." *U. S.*

"Take of the Saccharine Carbonate of Iron *four parts;* Conserve of Red Roses *one part.* Beat them into a proper mass, to be divided into five-grain pills." *Ed.*

The effect of saccharine matter in protecting iron from oxidation has been explained under the heads of *Ferri Carbonas Saccharatum* and *Liquor Ferri Iodidi.* The *U. S.* pill of carbonate of iron is another example of a ferruginous

preparation, in which the iron is protected from further oxidation by the same means. The salts employed are the same as those used for obtaining the officinal subcarbonate of iron; but, in forming that preparation, the carbonate which is at first precipitated absorbs oxygen and loses nearly all its carbonic acid in the processes of washing and drying. When, however, as in the U. S. formula, above given, the reacting salts are dissolved in weak syrup instead of water, and the washing is performed with the same substance, the absorption of oxygen and loss of carbonic acid, during the separation of the precipitate, are almost completely prevented. It only remains, therefore, to preserve it unaltered, and to bring it to the pilular consistence, and this is effected by admixture with honey and sugar, and evaporation by means of a water-bath. Of course it is essential to the success of this process, that the sulphate of iron should be pure; otherwise some sesquioxide will be present in the product. The process just explained is that of M. Vallet, of Paris, after whom the preparation is popularly called. The *Edinburgh* pill of carbonate of iron is made from the saccharine carbonate, which is brought to the pilular consistence by being mixed with conserve of roses. This mode of making it is inferior to that of Vallet; for, in the first place, the saccharine carbonate is admitted to contain sesquioxide of iron, and secondly conserve of roses is a less efficient preservative of the pilular mass than honey and sugar. (See *Ferri Carbonas Saccharatum.*)

Properties. The U. S. preparation is in the form of a soft pilular mass, of a uniform black colour, and strong ferruginous taste. When carefully prepared, it is wholly and readily soluble in acids. It contains nearly half its weight of carbonate of protoxide of iron. The corresponding pill, obtained from the saccharine carbonate, may be supposed to contain one-third of ferruginous matter.

Medical Properties. The U. S. pill of carbonate of iron, or Vallet's ferruginous mass, is admirably adapted to cases in which ferruginous preparations are indicated. It is considered particularly useful in chlorosis, amenorrhœa, and other female complaints, and appears to act favourably by increasing the colouring matter of the blood, causing the capillary system to become more fully injected, and the lips to assume a redder colour. It may be given in divided doses to the extent of from ten to thirty grains in the course of the day, and continued for a month or six weeks, if improvement takes place. As the mass is not divided in the U. S. formula, it is necessary in prescription to indicate the weight of each pill, which may vary from three to five grains, according to the views of the prescriber. There can be but little doubt that, in cases in which the alterative effects of iron are called for, Vallet's preparation is one of the best that can be employed. Its chief merits are its unchangeableness and ready solubility in acids. For further information respecting it, see the favourable report made on Vallet's ferruginous pills to the French Royal Academy of Medicine, in 1837, by M. Soubeiran, republished in the *Am. Journ. of Pharm.*, x. 244, and the paper on carbonate of iron by Professor Procter, contained in the same journal, x. 272. B.

PILULÆ FERRI COMPOSITÆ. *U. S.* Pilula Ferri Composita. *Lond. Compound Pills of Iron.*

"Take of Myrrh, in powder, *two drachms;* Carbonate of Soda, Sulphate of Iron, each, *a drachm;* Syrup *a sufficient quantity.* Rub the Myrrh with the Carbonate of Soda; then add the Sulphate of Iron, and again rub them; lastly, beat them with the Syrup so as to form a mass, to be divided into eighty pills." *U. S.*

The directions of the *London College* are essentially the same as the above, *a drachm* of molasses being substituted for the indefinite quantity of syrup, and the previous heating of the mortar ordered. The London preparation is not divided into pills.

This preparation is closely analogous to the Mistura Ferri Composita in properties and composition. It is a good emmenagogue and antihectic tonic. As its peculiar advantages depend upon the presence of carbonate of protoxide of iron, which speedily changes into the sesquioxide on exposure, it is proper that only so much of the mass should be prepared as may be wanted for immediate use. It is said that the iron will be better preserved in the state of protoxide, if, instead of mixing the ingredients as directed in the Pharmacopœia, the operator should first dissolve the sulphate of iron, finely powdered, in the syrup, with a moderate heat, then add the carbonate of soda, stirring till effervescence ceases, and lastly incorporate the myrrh. From two to six pills may be given at a dose, three times a day. W.

PILULÆ FERRI IODIDI. *U. S.* *Pills of Iodide of Iron.*

"Take of Sulphate of Iron *a drachm;* Iodide of Potassium *four scruples;* Tragacanth, in powder, *ten grains;* Sugar, in powder, *half a drachm.* Beat them with Syrup so as to form a mass, to be divided into forty pills." *U. S.*

These pills are formed on the plan proposed by M. Calloud. The iodide of iron results from a double decomposition between crystallized sulphate of protoxide of iron and iodide of potassium; and sulphate of potassa is at the same time formed, which, consequently, is an ingredient in the pill. There is also present some iodide of potassium, which is taken in a quantity more than sufficient to decompose all the sulphate of iron. In forming the pill, the sulphate and iodide should be rubbed together until they are thoroughly mixed; after which the sugar and tragacanth should be incorporated, and lastly the syrup. The sugar used is intended to protect the iodide of iron formed from oxidation.

This pill is a new officinal of the U. S. Pharmacopœia of 1850. It was considered desirable to have a pill of iodide of iron; and as the officinal iodide does not keep well, and is not readily made into pills, it was thought by the revisers of our national standard that the process of Calloud, by double decomposition, would, probably, furnish a convenient extemporaneous pill, which would not be injured by the presence of a little sulphate of potassa. But the presence also of some iodide of potassium also renders it still more complex, and forms an objection to it. This pill should never be kept, but made only when wanted for immediate use. It is rather friable in its consistence, and exhales iodine slightly when made for some time. Its taste is styptic and rather acrid, and it is, therefore, unpleasant to swallow. It may be presumed to create some irritation of the stomach before it is dissolved. When freshly prepared, each pill contains a little over a grain and a half of iodide of iron. The therapeutic applications of this preparation are the same as those of the solution of iodide of iron. (See *Liquor Ferri Iodidi.*) The latter, however, is in all respects a preferable form. For other formulæ for making a pill of iodide of iron from the solid iodide directly, see *Ferri Iodidum*, page 1005. B.

PILULÆ FERRI SULPHATIS. *Ed.* *Pills of Sulphate of Iron.*

"Take of Dried Sulphate of Iron *two parts;* Extract of Taraxacum *five parts;* Conserve of Red Roses *two parts;* Liquorice-root powder *three parts.* Beat them together into a proper mass, which is to be divided into five-grain pills." *Ed.*

There may be some doubt of the propriety of mixing the sulphate of iron with the confection of roses, by the tannic acid of which it must be decomposed. The dose is from five to twenty grains. W.

PILULÆ GALBANI COMPOSITÆ. *U.S.* PILULA GALBANI COMPOSITA. *Lond.* PILULÆ ASSAFŒTIDÆ. *Ed.* PILULÆ ASSAFŒTIDÆ COMPOSITÆ. *Dub.* *Compound Pills of Galbanum.*

"Take of Galbanum, Myrrh, each, *six drachms;* Assafetida *two drachms;*

Syrup *a sufficient quantity.* Beat them together, so as to form a mass, to be divided into two hundred and forty pills." *U. S.*

The *London College* beats together into a mass *two drachms* of prepared galbanum, *three drachms*, each, of myrrh and prepared sagapenum, *a drachm* of prepared assafetida, *two drachms* of soft soap, and *a sufficient quantity* of molasses. The *Edinburgh College* takes of assafetida, galbanum, and myrrh, each, *three parts*, conserve of red roses *four parts* or *a sufficient quantity*, mixes them, and beats them into a proper pilular mass. The *Dublin College* takes *two ounces* of assafetida, and *an ounce*, each, of galbanum, myrrh, and molasses, heats them in a capsule, by means of a steam or water bath, and stirs the mass until it assumes a uniform consistence.

This compound is given as an antispasmodic and emmenagogue in chlorosis and hysteria. The dose is from ten to twenty grains. W.

PILULÆ HYDRARGYRI. *U. S., Ed., Dub.* PILULA HYDRARGYRI. *Lond. Mercurial Pills. Blue Pills.*

"Take of Mercury *an ounce;* Confection of Roses *an ounce and a half;* Liquorice Root, in powder, *half an ounce.* Rub the Mercury with the Confection till all the globules disappear; then add the Liquorice Root, and beat the whole into a mass, to be divided into four hundred and eighty pills." *U. S.*

The process of the *London College* is the same with the above, one-half only of the quantity of materials being used. The *Dublin* process differs only in about doubling the quantity of the materials. Neither of these Colleges orders the mass to be divided into pills. The *Edinburgh* process corresponds with that of the U. S. Pharmacopœia, except that the relative quantity of the ingredients is expressed in parts, and the mass is divided into five-grain pills.

This preparation is very generally known by the name of *blue pill* or *blue mass.* The mercury constitutes one-third of the mass; and consequently the pill of our Pharmacopœia, which weighs three grains, contains one grain of the metal.

The precise condition of the mercury in this preparation is somewhat uncertain. By far the greater portion is in a state of minute mechanical division, and not chemically altered. Some maintain that the whole of the metal is in this state, others, that a small portion is converted during the trituration into protoxide, and that this is the ingredient upon which the activity of the pill depends. The supposed oxidation is attributed partly to the influence of the air upon the surface of the metal, greatly extended by the separation of its particles, partly to the action of the substance used in the trituration. If the mercury be not oxidized during the trituration, there can be little doubt that it becomes so to a slight extent by subsequent exposure. The obvious changes which the mass undergoes by time can be explained in no other way; and protoxide of mercury is asserted to have been actually extracted from old mercurial pill. Nevertheless, it scarcely admits of dispute, that the metal, quite independently of oxidation out of the body, is capable of producing the peculiar mercurial effects when introduced into the stomach, probably undergoing chemical changes there. According to M. Mialhe, mercury is slowly converted into corrosive sublimate in the stomach, under the combined agency of air and chloride of sodium. All agree that the efficacy of the preparation is proportionate to the extinction of the mercury, in other words, to the degree in which the metallic globules disappear. This extinction may be effected by trituration with various substances; and manna, syrup, honey, liquorice, mucilage, soap, guaiac, and extract of dandelion have been recommended, among others, for this purpose; but the confection of roses has been adopted in all the Pharmacopœias, as less liable to objection than any other. The mercury is known to be completely extinguished, when, upon rubbing a small portion of the mass with the end of the finger upon a piece of paper or glass, no globules appear. Powdered liquorice root is added in order

to give due consistence to the mass. Some prefer for the purpose powdered marshmallow root. As the trituration requires to be long continued, and renders the process very laborious, it is customary to prepare the mass by machinery. At Apothecaries' Hall, in London, the trituration is effected by the agency of steam. The machine there employed consists of "a circular iron trough for the reception of the materials, in which revolve four wooden cylinders, having also a motion on their axis." A machine for preparing blue mass, capable of being worked by the hand or by steam-power, has been invented by Mr. J. W. W. Gordon, of Baltimore, and, having been found to answer well, is in extensive use. It is described and figured in the *American Journal of Pharmacy* (xxi. 6).* Formerly much of the blue mass used in this country was imported; but at present the market is chiefly supplied by our own druggists. The preparation slowly changes colour upon being kept, assuming an olive and sometimes even a reddish tint, in consequence, probably, of the further oxidation of the mercury.†

Medical Properties and Uses. These pills are among the mildest of the mercurials, being less liable than most others to act upon the bowels, and exercising the peculiar influence of the remedy upon the system with less irritation. They are much employed for producing the sialagogue and alterative action of mercury. For the former purpose, one pill may be given two or three times a day; and in urgent cases the dose may be increased. Even this preparation sometimes disturbs the bowels. It should then be given combined with a little opium, or in very minute doses, as half a grain or a grain of the mass repeated every hour or two through the day, so as to allow of its absorption before a sufficient quantity has been administered to act as an irritant. With a view to the alterative effect upon the digestive organs, one pill may be given every night, or every other night, at bedtime, and followed in the morning, if the bowels should not be opened, by a small dose of laxative medicine. From five to fifteen grains of the mass are occasionally given as a cathartic, in cases requiring a peculiar impression upon the liver; but when used for this purpose, it should always either be combined with or speedily followed by a more certain purgative. The *blue mass* may frequently be administered with advantage, suspended in water by the intervention of thick mucilage; and it forms an excellent addition to the chalk mixture in diarrhœa, particularly that of children, when the biliary secretion is deficient, or otherwise deranged. W.

* Mr. James Beatson, Apothecary of the U. S. Naval Hospital at New York, has found great advantage in the following mode of preparing the mercurial pill, which, while much easier than the officinal method, yields the same results. Instead of mixing the mercury with the confection, he first rubs it with the honey directed in the preparation of the confection, until the globules disappear, then adds the heated rose water and sugar, and lastly the powdered red roses and liquorice root in succession, all in the officinal proportions. For the quantity of the material directed in the U. S. process for the confection of roses, he employs 32 ounces of mercury. (*Am. Journ. of Pharm.*, xxiv. 204.)

† This preparation is very apt to contain less than the due proportion of mercury. This was frequently the case with the mass as formerly imported. The fraud may be detected by the following plan of estimating the proportion of mercury, suggested by Prof. Reid of New York, and modified by a committee of the Philadelphia College of Pharmacy. A certain weight of the mercurial pill, say fifty grains, is mixed with about one-fourth of its weight of iron filings, and introduced into a small green glass bulb, at the end of a somewhat curved tube, the open extremity of which is inserted through a cork, into alcohol contained in a broad-mouthed glass vial; another tube, open at both ends, passing through the cork in order to permit the escape of uncondensed gases. Heat is then applied to the bulb by means of a spirit lamp, is gradually increased until the glass becomes red-hot, and continued for an hour. The alcohol in the vial dissolves the empyreumatic products, and, by being allowed to rise in the tube, and then expelled, serves to wash out any mercury that may be condensed upon its sides. The alcohol is poured off from the condensed mercury, which is then washed with fresh alcohol, dried, and weighed. (See *Am. Journ. of Pharm.*, xvii. 151 and 309.)

PILULÆ HYDRARGYRI CHLORIDI MITIS. *U.S.* *Pills of Mild Chloride of Mercury. Calomel Pills.*

"Take of Mild Chloride of Mercury [calomel] *half an ounce;* Gum Arabic, in powder, *a drachm;* Syrup *a sufficient quantity.* Mix together the Chloride of Mercury and the Gum; then beat them with the Syrup so as to form a mass, to be divided into two hundred and forty pills." *U. S.*

This is a convenient form for administering calomel, of which one grain is contained in each pill. Soap, which was directed in the preparation of this pill in the first edition of the Pharmacopœia, is objectionable on account of its chemical incompatibility with calomel.* Mucilage of gum Arabic alone does not form a sufficiently plastic mass; but gum and syrup united, as in the officinal formula, answer admirably well, forming a mass which is easily made into pills, and which readily yields to the solvent power of the stomach. W.

PILULA IPECACUANHÆ CUM SCILLÂ. *Lond.* *Pill of Ipecacuanha with Squill.*

"Take of Compound Powder of Ipecacuanha [Dover's powder] *three drachms;* Squill, recently powdered, Ammoniac, in powder, each, *a drachm;* Molasses a *sufficient quantity.* Beat them together so as to form a mass." *Lond.*

An anodyne, somewhat stimulating, and expectorant combination, applicable to cases of chronic bronchial disease. The dose is from five to ten grains. W.

PILULÆ IPECACUANHÆ ET OPII. *Ed.* *Pills of Ipecacuanha and Opium.*

"Take of Powder of Ipecacuan and Opium *three parts;* Conserve of Red Roses *one part.* Beat them into a proper mass, which is to be divided into four-grain pills." *Ed.*

This is merely the Dover's powder in a pilular form; as there can scarcely be a doubt that the College intended by the name "powder of ipecacuan and opium," to designate the preparation which they now call "compound powder of ipecacuanha." These pills are narcotic and sudorific. The quantity of the mass equivalent to a grain of opium is about thirteen grains; but it is usually employed in smaller doses. W.

PILULÆ OPII. *U.S.* PILULÆ OPII *sive* THEBAICÆ. *Ed.* *Pills of Opium.*

"Take of Opium, in powder, *a drachm;* Soap *twelve grains.* Beat them with water so as to form a mass, to be divided into sixty pills." *U. S.*

"Take of Opium *one part;* Sulphate of Potassa *three parts;* Conserve of Red Roses *one part.* Beat them into a proper mass, which is to be divided into five-grain pills." *Ed.*

The process of the U. S. Pharmacopœia is designed merely to furnish a convenient formula for putting opium into the pilular form, preferable to the mode sometimes practised of making the pills directly from the unpowdered mass of opium as found in commerce. The soap answers no other purpose than to give a due consistence, and is therefore in small proportion. Each pill contains a grain of opium.

* In order to test the point of this presumed incompatibility, Prof. Procter, at our request, made some experiments, from which it resulted that a hot solution of pure white Castile soap, allowed to cool, produces no change in calomel with which it is agitated; but that, if the same solution is heated with calomel, a somewhat vigorous reaction takes place, resulting, by double decomposition, in the production of chloride of sodium, and oleo-margarate of the protoxide of mercury. But the experiment does not decide, whether long contact between calomel and soap, as in the form of pill, might not be followed by the same effects as when heat is employed. There can be no doubt of the incompatibility of calomel and common soap with an excess of alkali.—*Note to the tenth edition.*

The object intended to be answered by the Edinburgh preparation is somewhat uncertain. The proportion of the opium corresponds with that in the *Pilulæ Saponis Compositæ* of the other Pharmacopœias, but the name given to the preparation indicates that there could be no intention to conceal its nature; while the direction to divide the mass into pills of five grains, each containing a grain of opium, shows that the design was not to offer the means of exhibiting small doses of that narcotic in the pilular form. The object probably was merely to separate the particles of opium by the intervention of sulphate of potassa, and thus to render it more soluble in the gastric liquors. In this case, the preparation ranks rather with the U. S. *pills of opium*, with which we have placed it, than with the *compound pills of soap.*

As hard old opium pills are sometimes preferred, in cases of irritable stomach, in consequence of their slow solution, it is proper for the apothecary to keep some in this state to meet the prescription of the physician.

Of either of the officinal pills above directed, one is a medium dose in reference to the full effects of opium. W.

PILULÆ PLUMBI OPIATÆ. *Ed. Opiate pills of Lead.*

"Take of Acetate of Lead *six parts;* Opium *one part;* Conserve of Red Roses about *one part.* Beat them into a proper mass, which is to be divided into four-grain pills. This pill may be made also with twice the quantity of opium." *Ed.*

This pill would be better left to extemporaneous prescription; the requisite proportion of opium to the acetate varying in different cases. Besides, to have two preparations under the same name, one containing twice as much opium as the other, must lead to confusion, and is altogether objectionable. The tannic acid of the confection of roses decomposes a portion of the acetate; but the resulting tannate of lead is not inert. Each pill contains three grains of acetate of lead, which is generally too much for a commencing dose. W.

PILULÆ QUINIÆ SULPHATIS. *U. S. Pills of Sulphate of Quinia.*

"Take of Sulphate of Quinia *an ounce;* Gum Arabic, in powder, *two drachms;* Honey *a sufficient quantity.* Mix together the Sulphate of Quinia and the Gum; then beat them with the Honey so as to form a mass, to be divided into four hundred and eighty pills." *U. S.*

As the pills made as here directed are apt to become hard, and of difficult solubility when long kept, various other excipients have been recommended to obviate this disadvantage, as honey alone, and confection of roses. Mr. Edward Parrish has long been in the habit of preparing pills of sulphate of quinia, by taking 20 grains of the salt, adding 15 drops of aromatic sulphuric acid, and triturating with a spatula until the mixture assumes a pilular consistence. Though at first liquid, the mixture soon thickens, and finally becomes quite solid. The officinal sulphate is thus rendered more soluble by combining with an additional eq. of sulphuric acid. The advantages of this process are the solubility of the resulting pill, and the smallness of its bulk. A five-grain pill made in this way is not inconveniently large. (*Am. Journ. of Pharm.*, xxv. 292.)

Each of the officinal pills contains a grain of sulphate of quinia, and twelve are equivalent to an ounce of good Peruvian bark. W.

PILULÆ RHEI. *U. S., Ed. Pills of Rhubarb.*

"Take of Rhubarb, in powder, *six drachms;* Soap *two drachms.* Beat them with water so as to form a mass, to be divided into one hundred and twenty pills." *U. S.*

"Take of Rhubarb, in fine powder, *nine parts;* Acetate of Potash *one part;* Conserve of Red Roses *five parts.* Beat them into a proper mass, and divide it into five-grain pills." *Ed.*

Rhubarb is so often given in the pilular form, that it is convenient both for the physician and apothecary to have an officinal formula, indicating the mode of preparing the pills, as well as the quantity of rhubarb to be contained in each. Soap, as directed by the U. S. Pharmacopœia, has stood the test of long experience as a good excipient for rhubarb. The medicine is sufficiently disposed to constipate without the addition of the confection of roses, ordered by the Edinburgh College. The acetate of potassa directed by the College is probably intended to keep the pill soft. The U. S. formula is decidedly preferable. According to both, each pill contains three grains of rhubarb. W.

PILULÆ RHEI COMPOSITÆ. *U. S.*, *Ed.*, *Dub.* PILULA RHEI COMPOSITA. *Lond.* *Compound Pills of Rhubarb.*

"Take of Rhubarb, in powder, *an ounce;* Aloes, in powder, *six drachms;* Myrrh, in powder, *half an ounce;* Oil of Peppermint *half a fluidrachm.* Beat them with water so as to form a mass, to be divided into two hundred and forty pills." *U. S.*

The *London College* takes *half of the above quantities* of powdered rhubarb, aloes, and myrrh; mixes them; then adds *half a drachm* of soft soap, *fifteen minims* of oil of caraway, and *sufficient* molasses; and beats them all together. The *Edinburgh College* takes of rhubarb *twelve parts*, aloes *nine parts*, myrrh and Castile soap, each, *six parts*, oil of peppermint *one part*, and conserve of red roses *five parts;* mixes them, and beats them into a mass, which is divided into five-grain pills. This College also allows the pills to be made without oil of peppermint, when so preferred. The *Dublin College* uses the same ingredients as the *Edinburgh*, in the same relative proportions, except that sixteen parts of molasses are used instead of five parts of conserve of roses. The proportion of molasses ("treacle," *Dub.*) is so large that we suspect some error of the press.

This is a warm tonic laxative, useful in costiveness with debility of stomach. From two to four pills, or from ten to twenty grains of the mass, may be taken twice a day. W.

PILULÆ RHEI ET FERRI. *Ed.* *Pills of Rhubarb and Iron.*

"Take of Dried Sulphate of Iron *four parts;* Extract of Rhubarb *ten parts;* Conserve of Red Roses *five parts.* Beat them into a proper pill mass, and divide it into five-grain pills." *Ed.*

Tonic and laxative in the dose of two or three pills. W.

PILULÆ SAPONIS COMPOSITÆ. *U. S.*, *Dub.* PILULA SAPONIS COMPOSITA. *Lond.* *Compound Pills of Soap.*

"Take of Opium, in powder, *half an ounce;* Soap *two ounces.* Beat them with water so as to form a pilular mass." *U. S.*

The *London College* takes of opium and liquorice root, each, in powder, *two drachms*, of soft soap *six drachms*, and beats them into a mass; the *Dublin* takes of opium, in fine powder, *half an ounce* [avoirdupois], Castile soap *two ounces* [avoird.], and of distilled water *half a fluidrachm* or *a sufficiency*, reduces the soap to a fine powder, adds the opium and water, and beats into a mass.

This preparation is useful by affording the opportunity of conveniently administering opium, in a pilular and readily soluble form, in small fractions of a grain. The name adopted in the Pharmacopœias was probably intended to conceal the nature of the preparation from the patient. One grain of opium is contained in five of the mass. W.

PILULÆ SCILLÆ COMPOSITÆ. *U. S.*, *Dub.* PILULA SCILLÆ COMPOSITA. *Lond.* PILULÆ SCILLÆ. *Ed.* *Compound Pills of Squill.*

"Take of Squill, in powder, *a drachm;* Ginger, in powder, Ammoniac, in powder, each, *two drachms;* Soap *three drachms;* Syrup *a sufficient quantity.*

Mix the powders together; then beat them with the Soap, and add the Syrup so as to form a mass, to be divided into one hundred and twenty pills." *U. S.*

The *London College* employs the same materials, in the same quantities, except that it substitutes soft soap for Castile soap, and *a drachm* of molasses for the sufficiency of syrup; and completes the process in the same manner, but without dividing the mass. The *Edinburgh College* takes of squill, in fine powder, *five parts;* ammoniac, ginger, in fine powder, and Spanish soap, each, *four parts;* conserve of red roses *two parts;* mixes the powders; then adds the other ingredients; and beats them into a uniform mass, which is divided into five-grain pills. The *Dublin College* reduces *two ounces* [avoirdupois] of Castile soap to fine powder, adds *half an ounce* [avoird.] of finely powdered opium, and *half a fluidrachm* or *as much as may be sufficient* of distilled water, and beats the mixture into a uniform mass.

This is a stimulant expectorant compound, depending for its virtues chiefly on the squill, and applicable to the treatment of chronic affections of the bronchial mucous membrane. From five to ten grains may be given three or four times a day. The preparation should be made when wanted for immediate use, as the squill which it contains is liable to be injured by keeping. W.

PILULA STYRACIS COMPOSITA. *Lond.* PILULÆ STYRACIS. *Ed. Compound Pill of Storax.*

"Take of Prepared Storax *six drachms;* Opium, in powder, Saffron, each, *two drachms.* Beat them together, so as to form a mass." *Lond.*

The *Edinburgh College* takes of opium and saffron, each, *one part*, and of extract of storax *two parts*, and beats them into a uniform mass, which is divided into four-grain pills.

In these pills, the storax and saffron are added merely to conceal the taste and smell of the opium, as the name of the pills is intended to conceal their real character. This contrivance is deemed necessary; as some individuals have a prejudice against the use of opium, which reason cannot overcome. Five grains of the mass contain a grain of opium. W.

PLUMBUM.

Preparations of Lead.

LIQUOR PLUMBI SUBACETATIS. *U.S., Dub.* LIQUOR PLUMBI DIACETATIS. *Lond.* PLUMBI DIACETATIS SOLUTIO. *Ed. Solution of Subacetate of Lead.*

"Take of Acetate of Lead *sixteen ounces;* Semivitrified Oxide of Lead, in fine powder, *nine ounces and a half;* Distilled Water *four pints.* Boil them together in a glass or porcelain vessel for half an hour, occasionally adding Distilled Water so as to preserve the measure, and filter through paper. Keep the solution in closely stopped bottles." *U. S.* The sp. gr. of this solution is 1·267.

"Take of Acetate of Lead *two pounds and three ounces;* Oxide of Lead [litharge], rubbed into powder, *a pound and four ounces;* Distilled Water *six pints* [Imperial measure]. Boil for half an hour, occasionally stirring, and, when the solution has cooled, add enough Distilled Water to make it fill six pints [Imp. meas.]; lastly filter. Let it be kept in well stopped bottles." *Lond.* The sp. gr. of the solution is 1·260.

"Take of Acetate of Lead *six ounces and six drachms;* Litharge, in fine powder, *four ounces;* Water *a pint and a half* [Imperial measure]. Boil the Salt and Litharge with the Water for half an hour, stirring occasionally. When the solution is cold add Water, if necessary, to make up a pint and a half [Imp. meas.]; and then filter. Preserve the solution in well closed bottles." *Ed.*

"Take of Acetate of Lead *six ounces* [avoirdupois]; Litharge, in fine powder, *four ounces* [avoird.]; Distilled Water *two pints* [Imperial measure]. Dissolve the Acetate of Lead in the Water, and, when the solution is raised to its boiling temperature, add the Litharge in successive portions, and boil gently for half an hour. Add now as much distilled water as will supply what has been lost by evaporation, and filter through paper into a bottle, which should be furnished with an air-tight stopper. The sp. gr. of this solution is 1·066." *Dub.*

Crystallized acetate of lead consists of one equivalent of acetic acid 51, one of protoxide of lead 111·6, and three of water 27=189·6. Litharge, as usually found in the shops, is an impure protoxide of lead. When a solution of the former is boiled with the latter, a large quantity of the protoxide is dissolved, and a subacetate of lead is formed, which remains in solution. The precise composition of the subacetate varies with the proportion of acetate of lead and of litharge employed. When the quantity of the latter exceeds that of the former by one-half or more, the acetic acid of the acetate unites, according to the highest chemical authorities, with two additional equivalents of protoxide, forming a tris-acetate; when the two substances are mixed in proportions corresponding with their equivalent numbers, that is, in the proportion of 189·6 of salt to 111·6 of oxide, or 10 to 6 nearly, only one additional equivalent of protoxide unites with the acid, and a diacetate of lead is produced. In all the present officinal processes, the proportions appear to have been arranged in reference to this result. In executing the process, the litharge should be employed in the state of very fine powder, and, according to Thenard, should be previously calcined in order to decompose the carbonate of lead, which it always contains in greater or less proportion, and which is not dissolved by the solution of the acetate.

In former editions of the London and Dublin Pharmacopœias, a different process was directed, consisting in boiling litharge with distilled vinegar, the former being in much larger proportion than necessary to form the neutral acetate. A diacetate was thus produced; but as the vinegar was of uncertain strength, there was necessarily more or less inequality of strength in the preparation. This process, therefore, has been abandoned. The solution prepared from litharge and distilled vinegar has a pale greenish-straw colour, owing to impurities in the vinegar. When made with common vinegar it is brown.

Properties. The solution of subacetate of lead of the Pharmacopœias is colourless, and of a sweetish, astringent taste. When concentrated by evaporation, it deposits on cooling crystalline plates, which, according to Dr. Barker, are flat rhomboidal prisms, with dihedral summits. It has an alkaline reaction, tinging the syrup of violets green, and reddening turmeric paper. One of its most striking properties is the extreme facility with which it is decomposed. Carbonic acid throws down a white precipitate of carbonate of lead; and this happens by mere exposure to the air, or by mixture even with distilled water, if this has had an opportunity of absorbing carbonic acid from the atmosphere. It affords precipitates also with the alkalies, alkaline earths, and their carbonates, with sulphuric and muriatic acids free or combined, with hydrosulphuric acid and the hydrosulphates, with the soluble iodides and chlorides, and, according to Thenard, with solutions of all the neutral salts. Solutions of gum, tannin, most vegetable colouring principles, and many animal substances, particularly albumen, produce with it precipitates consisting of the substance added and oxide of lead. It should be kept in well stopped bottles. It is known to contain a salt of acetic acid by emitting an acetous smell when treated with sulphuric acid; and a salt of lead by yielding a white precipitate with an alkaline carbonate, a yellow one with iodide of potassium, and a black one with hydrosulphuric acid. It is distinguished from the solution of acetate of lead by being precipitated by gum Arabic.

Medical Properties and Uses. This solution is astringent and sedative, but is employed only as an external application. It is highly useful in inflammation arising from sprains, bruises, burns, blisters, &c., to which it is applied by means of linen cloths, which should be removed as fast as they become dry. It always, however, requires to be diluted. From four fluidrachms to a fluidounce, added to a pint of distilled water, forms a solution sufficiently strong in ordinary cases of external inflammation. When applied to the skin denuded of the cuticle, the solution should be still weaker; as constitutional effects might result from the absorption of the lead. Paralysis is said to have been produced by its local action; but we have not witnessed such an effect. The solution has the common name of *Goulard's extract*, derived from a surgeon of Montpellier, by whom it was introduced into general notice, though previously employed.

Off. Prep. Ceratum Plumbi Subacetatis; Ceratum Saponis; Liquor Plumbi Subacetatis Dilutus. W.

LIQUOR PLUMBI SUBACETATIS DILUTUS. *U. S.* LIQUOR PLUMBI DIACETATIS DILUTUS. *Lond.* PLUMBI SUBACETATIS LIQUOR COMPOSITUS. *Dub. Diluted Solution of Subacetate of Lead. Lead-water.*

"Take of Solution of Subacetate of Lead *two fluidrachms;* Distilled Water *a pint.* Mix them." *U. S.*

The *London College* mixes *a fluidrachm and a half* of the solution with *a pint* [Imperial measure] of distilled water, and *two fluidrachms* of proof spirit; the *Dublin*, *two fluidounces* of the solution, with *half a gallon* [Imp. meas.] of distilled water, and *two fluidounces* of proof spirit.

This preparation is convenient; as, in consequence of the subsidence of the carbonate of lead usually formed on the dilution of the strong solution, it enables the apothecary to furnish clear lead-water when it is called for. The strength of the U. S. preparation, though double what it formerly was, might be still further increased without disadvantage. The London preparation is much too feeble. The Dublin College in its Pharmacopœia for 1850 has about tripled the former strength; and its solution is about one-third stronger than that of our own Pharmacopœia. The old French Codex directed two drachms of the strong solution to a pound of distilled water, and an ounce of alcohol of 22° Baumé, and thus formed the *vegeto-mineral water* of Goulard. The minute proportion of proof spirit added by the British Colleges can have little sensible effect. The preparation should be as much as possible excluded from the air. W.

PLUMBI IODIDUM. *U. S.*, *Lond.*, *Ed.*, *Dub.* *Iodide of Lead.*

"Take of Nitrate of Lead, Iodide of Potassium, each, *four ounces;* Distilled Water *a sufficient quantity.* With the aid of heat, dissolve the Nitrate of Lead in a pint and a half, and the Iodide of Potassium in half a pint of Distilled Water, and mix the solutions. Having allowed the insoluble matter to subside, pour off the supernatant liquid, wash the precipitate with Distilled Water, and dry it with a gentle heat." *U. S.*

"Take of Acetate of Lead *eight ounces;* Iodide of Potassium *seven ounces;* Distilled Water *a gallon* [Imperial measure]. Dissolve the Acetate in six pints of the Water, and filter; and to these add the Iodide of Potassium previously dissolved in two pints of the Water. Wash the precipitate with cold distilled water and dry it. Let it be kept excluded from the light." *Lond.*

"Take of Iodide of Potassium and Nitrate of Lead, of each, *an ounce;* Water *a pint and a half* [Imperial measure]. Dissolve the salts separately, each in one-half of the Water; add the solutions; collect the precipitate on a filter of linen or calico, and wash it with water. Boil the powder in three gallons of water acidulated with three fluidounces of Pyroligneous Acid [acetic acid]. Let any undissolved matter subside, maintaining the temperature near the boiling

point; and pour off the clear liquor, from which the Iodide of Lead will crystallize on cooling." *Ed.*

The *Dublin* process differs from that of the U. S. Pharmacopœia simply in the use of a much larger proportion of water of solution, and in directing the two solutions to be cold before being mixed.

In the U. S. process the nitrate of lead gives up its metal to the iodine, from which it receives the potassium; the operation taking place between single equivalents of the several ingredients. The nitrate of potassa thus formed remains in solution, while the iodide of lead is precipitated. The saturating proportions of nitrate of lead and iodide of potassium are 165·6 of the former and 165·5 of the latter, or almost precisely equal quantities. The proportions should be as nearly as possible those of exact saturation. An excess of the iodide of potassium, independently of the waste, has the disadvantage of holding a portion of the iodide of lead in solution; while, according to Christison, an excess of lead over the iodine disposes to the formation of the lemon-yellow insoluble oxyiodide of lead. By the use of equal quantities of the two salts, these disadvantages are avoided. As iodide of lead is slightly soluble in cold water, it is desirable to use as little of the menstruum as will answer; and hence the comparatively small proportion of water employed in the U. S. process.

The Edinburgh and Dublin processes are based upon the same principle as that of the U. S. Pharmacopœia. In both, however, an unnecessarily large proportion of water is employed. The iodide of potassium of commerce is apt to be contaminated with carbonate of potassa, which occasions a precipitation of carbonate of lead. It is to free the precipitated iodide of lead from this impurity, and from any oxyiodide that may be formed by an accidental excess of lead, that the Edinburgh College directs it to be boiled with water acidulated with acetic acid, which dissolves any carbonate or oxide of lead present, as well as the iodide, and deposits only the last upon cooling. But some waste is incurred in this operation; and it would be better to ascertain beforehand that the materials employed are pure.

In the process of the London College, acetate of lead is used instead of the nitrate. In the Pharmacopœia of 1836, an excess of the acetate was directed; but the error was corrected in the last edition. There are, however, other objections to this process. Acetate of lead is very liable to contain an excess of the oxide, and, as iodide of potassium is often impure, it follows that a portion of oxyiodide of lead will be very apt to form, even when the two materials are used apparently in mutually saturating proportions. To obviate the disadvantage of an excess of oxide in the acetate, it is recommended to add a little acetic acid to the solution of that salt before mixing it with the iodide of potassium.

M. Depaire, of Brussels, ascertained that, in the process in which acetate of lead and iodide of potassium are employed, a considerable amount of iodine remains in solution after the precipitation of the iodide of lead; and M. F. Boudet states that the quantity of the iodide resulting from the process is 10 per cent. less than theory would indicate. By the addition of nitric acid to the solution, after precipitation, an additional quantity of iodide of lead is obtained. M. Boudet ascribes this result to the formation of a portion of soluble iodide of potassium and lead, whenever iodide of lead and acetate of potassa are in contact. By substituting nitrate for acetate of lead, he found that a quantity of iodide of lead was obtained, as near that required by theory as the solubility of the iodide of lead permits. (*Journ. de Pharm.*, 3*e sér.*, xi. 274.)

From the above remarks it would appear that the process of the U. S. Pharmacopœia is on the whole to be preferred, and especially over that in which the acetate of lead is used, as the nitrate is more easily obtained pure. Some interesting experiments have been made by M. T. Huraut, of Paris, on the different

methods of preparing iodide of lead. It may be obtained by the reaction between any of the soluble iodides and the soluble salts of lead. It resulted from his observations that of the two salts of lead employed, the nitrate was to be preferred, and of the various iodides, though iodide of potassium yielded a very handsome product, yet iodide of calcium afforded one not inferior in quality, and somewhat greater in quantity. Upon a small scale, as the process is performed by the apothecary, the difference would be of little or no consequence; but it might be important to the manufacturer. (See *Am. Journ. of Pharm.*, xxi. 228.)

As obtained by the U.S., London, and Dublin processes, iodide of lead is in the form of a bright-yellow, heavy, tasteless, inodorous powder. It is soluble in 1235 parts of cold water (Soubeiran, *Trait. de Pharm.*), and 194 of boiling water, which, on cooling, deposits it in minute, shining, golden-yellow, crystalline scales. In this form it is presented by the Edinburgh process. It melts by heat, and is dissipated in vapours which are at first yellow, and ultimately violet in consequence of the disengagement of the iodine. It consists of one equivalent of iodine 126·3, and one of lead 103·6=229·9. As a test of its purity, the Edinburgh College states that five grains are entirely dissolved, with the aid of heat, by a fluidrachm of pyroligneous acid, diluted with a fluidounce and a half of distilled water; and golden crystals are copiously deposited when the solution cools. According to the London Pharmacopœia, 100 grains of it, dissolved at a boiling heat in nitric acid diluted with two parts of water, will, after the expulsion of the iodine, yield with sulphate of soda, a precipitate of sulphate of lead weighing 66 grains. It should be kept excluded from the light.

Medical Properties and Uses. This compound is supposed to have the resolvent properties of iodine, combined with those which are peculiar to lead, and was at one time recommended in tuberculous diseases, in which however it has proved wholly inefficient. It is said to have been usefully employed in the discussion of scrofulous tumours and other indolent swellings, and in the cure of obstinate ulcers; and for these purposes has been used both internally, and locally in the form of an ointment. According to Dr. Cogswell, if given for some time in small doses, it produces the effects of lead, but not those of iodine, upon the system. (*Christison's Dispensatory.*) The dose is from half a grain to three or four grains. Dr. O'Shaughnessy states that ten grains are borne without inconvenience.

POTASSA.

Preparations of Potassa.

LIQUOR POTASSÆ. *U. S.*, *Lond.* POTASSÆ AQUA. *Ed.* POTASSÆ CAUSTICÆ LIQUOR. *Dub.* *Solution of Potassa.*

"Take of Carbonate of Potassa *a pound;* Lime *half a pound;* Boiling Distilled Water *a gallon.* Dissolve the Carbonate of Potassa in half a gallon of the Water. Pour a little of the Water on the Lime, and, when it is slaked, add the remainder. Mix the hot liquors, and boil for ten minutes, stirring constantly; then set the mixture aside, in a covered vessel, until it becomes clear. Lastly, pour off the supernatant liquor, and keep it in well-stopped bottles of green glass. The specific gravity of this solution is 1·056." *U. S.*

"Take of Carbonate of Potassa *fifteen ounces;* Lime *eight ounces;* boiling Distilled Water *a gallon* [Imp. meas.]. Dissolve the Carbonate in half a gallon of the Water. Sprinkle a little of the Water upon the Lime in an earthen vessel, and, the Lime being slaked, add the remainder of the Water. The liquors being immediately mixed together in a close vessel, shake them frequently

until they are cold. Then set the mixture by, that the carbonate of lime may subside. Lastly, pour off the supernatant liquor, and keep it in a well stopped green glass bottle. The specific gravity is 1·063." *Lond.*

"Take of Carbonate of Potash (dry) *four ounces;* Lime, recently burnt, *two ounces;* Water *forty-five fluidounces* [Imp. meas.]. Let the lime be slaked and converted into milk of lime with seven fluidounces of the Water. Dissolve the Carbonate in the remaining thirty-eight fluidounces of Water; boil the solution, and add to it the milk of lime in successive portions, about an eighth at a time, boiling briskly for a few minutes after each addition. Pour the whole into a deep narrow glass vessel for twenty-four hours; and then withdraw with a syphon the clear liquid, which should amount to at least thirty-five fluidounces, and ought to have a density of 1·072." *Ed.*

"Take of Pure Carbonate of Potash *one pound* [avoirdupois]; fresh-burned Lime *ten ounces* [avoird.]; Distilled Water *one gallon and seven ounces* [Imp. meas.]. Slake the Lime with seven ounces of the Water. Dissolve the Carbonate of Potash in the remainder of the Water, and, having raised the solution to the boiling point in a clean iron vessel, gradually mix with it the slaked Lime, and continue the ebullition for ten minutes with constant stirring. Remove the vessel now from the fire, and when, by the subsidence of the insoluble matters, the supernatant liquor has become perfectly clear, transfer it by means of a syphon to a green glass bottle furnished with an air-tight stopper. The specific gravity of this solution is 1·068." *Dub.*

The object of these processes is to separate carbonic acid from the carbonate of potassa, so as to obtain the alkali in a caustic state. This is effected by hydrate of lime; and the chemical changes which take place are most intelligibly explained by supposing the occurrence of a double decomposition. The lime of the hydrate of lime, by its superior affinity, combines with the carbonic acid, and precipitates as carbonate of lime; while the water of the hydrate of lime unites with the potassa, and remains in solution as hydrate of potassa. The proportion indicated by theory for this decomposition would be 69·2 of the dry carbonate to 28·5 of lime, or one eq. of each; but in practice it is found necessary to use an excess of lime. In the U. S. and Edinburgh formulæ the alkaline salt is treated with half its weight of lime; in the London, with eight-fifteenths; and in the Dublin, with five-eighths; proportions, the lowest of which exceeds the theoretical quantity. The proportion of water employed has a decided influence on the result. If the water be deficient in quantity, the decomposing power of the lime, on account of its sparing solubility, will be lessened; and more of it will be required to complete the decomposition of the carbonate than if the solutions had been more dilute. Taking the lime at three ounces in each formula, the quantity of water directed in ounces is expressed by the following numbers nearly: 61½ *Ed.*, 60½ *U. S.*, 54 *Lond.*, and 45 *Dub.* Straining must not be used; as it causes a prolonged contact with the air, and risk of the absorption of carbonic acid, and is apt, moreover, to introduce organic matter from the strainer into the solution. The direction to keep the solution in green glass bottles is judicious; as white flint glass is slightly acted on.

As the solution of potassa is frequently made by the manufacturing chemist in considerable quantities, the following details, taken from Berzelius, of the best mode of conducting the process, may not be without their use. Dissolve one part of carbonate of potassa in from seven to twelve parts of water in a bright iron vessel, and decant the solution after it has become clear by standing. Boil the solution in an iron vessel, and while it is boiling, add, at intervals, small quantities of slaked lime, reduced to a thin paste with water; allowing the solution to boil a few minutes after each addition. One and a half parts of pure lime will be more than sufficient to decompose one part of the carbonate. When

about half the hydrate of lime has been added, take out about a teaspoonful of the boiling solution, and, after dilution and filtration through paper, test it by adding it to some nitric acid, or by mixing it with an equal bulk of lime-water. If the solution has not been completely freed from carbonic acid, the first reagent will cause an effervescence, and the second a milky appearance; in either of which events the addition of the lime must be continued as before, until the above-mentioned tests give negative indications. In conducting the process, several advantages are gained by keeping the solution constantly boiling. One is that the carbonate of lime formed is in this way rendered granular and heavy, and more disposed to subside; another, that it prevents the precipitated carbonate from coalescing into a mass at the bottom of the vessel, an occurrence which causes the ebullition, when subsequently renewed, to take place imperfectly and by jerks; and a third, that any silica present is precipitated in combination with lime and potassa. The process here described is essentially the same with those introduced into the last editions of the Edinburgh and Dublin Pharmacopœias.

According to M. Wöhler, pure hydrate of potassa in solution for analytic purposes may be conveniently obtained by exposing for half an hour to a moderate red heat, in a copper crucible, one part of pure nitre and two or three parts of copper, cut into small pieces. The resulting mass, consisting of hydrate of potassa and black oxide of copper, is treated with water, and the solution poured into a narrow cylindrical vessel, where it is left until it gets perfectly clear by the deposition of the oxide of copper. The solution is then drawn off with a syphon, and kept in well-stopped bottles. (*Chem. Gaz.*, Nov. 15, 1853, p. 429, from the *Ann. der Chem. und Pharm.*)

Properties, &c. Solution of potassa is a limpid, colourless liquid, without smell, and having an acrid caustic taste, and alkaline reaction. It acts rapidly on animal and vegetable substances, and when rubbed between the fingers, produces a soapy feel, in consequence of a partial solution of the cuticle. It dissolves gum, resins, and extractive matter, and by union with oily and fatty bodies forms soap. The U. S., London, and Edinburgh solutions are never pure, but contain either some undecomposed carbonate, or free lime, in addition to minute portions of sulphate of potassa, chloride of potassium, silica, and alumina; impurities usually present in the carbonate of potassa obtained from pearlash, which is used in their preparation. The Dublin solution, from the use of pure carbonate of potassa, is purer. Undecomposed carbonate may be detected in the manner explained in the preceding paragraph, and free lime, by the production of a milky appearance on the addition of a few drops of carbonate of potassa, which serves to precipitate the lime as a carbonate. When saturated with nitric acid, it gives little or no precipitate with carbonate of soda, chloride of barium, or nitrate of silver. With chloride of platinum it produces a yellow precipitate, showing that the alkali present is potassa. It is incompatible with acids, acidulous salts, and all metallic and earthy preparations held in solution by an acid; also with all ammoniacal salts, and with calomel and corrosive sublimate. The officinal solutions of potassa vary in strength; the U. S. solution having the specific gravity 1·056; the London, 1·063; the Edinburgh, 1·072; and the Dublin, 1·068. These solutions are quite dilute; that of the London College, which is of medium strength, containing only 6·7 per cent. of potassa. On account of its strong attraction for carbonic acid, the solution of potassa should be carefully preserved from contact with the air. B.

Medical Properties and Uses. Solution of potassa is antacid, diuretic, and antilithic. It has been much employed in calculous complaints, under the impression that it has the property of dissolving urinary concretions in the kidneys and bladder; but experience has proved that the stone once formed cannot be removed by remedies internally administered, and the most that the alkaline medicines can

effect, is to correct that disposition to the superabundant secretion of uric acid, or the insoluble urates, upon which gravel and stone often depend. For this purpose, however, the carbonated alkalies are preferable to caustic potassa, as they are less apt to irritate the stomach, and to produce injurious effects when long continued. It has been proposed to dissolve calculi by injecting immediately into the bladder the solution of potassa in a tepid state, and so much diluted that it can be held in the mouth; but this mode of employing it has not been found to answer in practice. This solution has also been highly recommended in lepra, psoriasis, and other cutaneous affections; and is said to have proved peculiarly useful in scrofula; but in all these cases it probably acts simply by its antacid property, and is not superior to the carbonate of potassa or of soda. Externally it has been used, in a diluted state, as a stimulant lotion in rachitis and arthritic swellings, and concentrated, as an escharotic in the bite of rabid or venomous animals. The dose is from ten to thirty minims, repeated two or three times a day, and gradually increased in cutaneous affections to one or two fluidrachms; but the remedy should not be too long continued, as it is apt to debilitate the stomach. It may be given in sweetened water or some mucilaginous fluid. Veal broth and table beer have been recommended as vehicles; but the fat usually present in the former would be liable to convert the alkali into soap, and the acid in the latter would neutralize it. In dyspeptic cases it may be associated with the simple bitters. In excessive doses it irritates, inflames, or corrodes the stomach. Oils and the milder acids, such as vinegar and lemon-juice, are the antidotes to its poisonous action. They operate by neutralizing the alkali.

It is employed pharmaceutically in the preparation of Oxide of Antimony, Precipitated Sulphuret of Antimony, Ethereal Oil, Hydrated Peroxide of Iron, Magnetic Oxide of Iron, and Oxide of Silver.

POTASSA. *U. S., Ed.* Potassæ Hydras. *Lond.* Potassa Caustica. *Dub. Potassa. Hydrate of Potassa. Caustic Potassa.*

"Take of Solution of Potassa *a gallon*. Evaporate the Solution rapidly in a clean iron vessel, over the fire, till ebullition ceases, and the Potassa melts. Pour this into suitable moulds, and keep it, when cold, in well stopped bottles." *U. S.*

The *London* formula is essentially the same with the above.

"Take *any convenient quantity* of Aqua Potassæ; evaporate it in a clean and covered iron vessel, increasing gradually the heat, till an oily-looking fluid remains, a drop of which, when removed on a rod, becomes hard on cooling. Then pour out the liquid upon a bright iron plate, and as soon as it solidifies, break it quickly, and put it into glass bottles secured with glass stoppers." *Ed.*

"Take of Solution of Caustic Potash *any convenient quantity*. Boil it in a silver or bright iron vessel, until its water has been evaporated away, and then raise the temperature until ebullition ceases, and a liquid is obtained which flows like oil. Pour this out upon a silver or iron dish, and, the moment it has set, break it into fragments, and enclose these in a green glass bottle, furnished with an air-tight stopper." *Dub.*

The concrete alkali, obtained by these processes, is the hydrate of potassa, sufficiently pure for medicinal purposes. The solution of the alkali freed from carbonic acid having been obtained by another formula (see *Liquor Potassæ*), the formation of the present preparation requires merely the evaporation of this solution, until the whole of its uncombined water is driven off. The evaporation is required to be performed in metallic vessels, as those of glass or earthenware are acted on by the alkali; and it should be completed as quickly as possible, in order to abridge the period during which the solution would be liable to absorb

carbonic acid from the atmosphere. When poured out on a metallic plate or dish, the cake, just as it concretes, may be marked with a knife in the directions in which it is to be divided, and when cold it readily breaks in those directions. A better plan, however, is to run the fused alkali into suitable moulds, as directed in the U. S. and London formulæ. These should be made of iron and have a cylindrical shape, which is the most convenient form of the alkali for the use of the surgeon. Green glass bottles with ground stoppers are the best adapted for preserving this preparation, as white flint glass is slightly acted on.

Properties, &c. In its officinal form, potassa is usually in sticks which have a fibrous fracture, a dingy gray or greenish colour, occasionally a bluish tint, and the peculiar odour of slaking lime. It is extremely caustic and very deliquescent, and dissolves in less than its weight of water, leaving but a slight residue. Its aqueous solution agrees in properties with Liquor Potassæ. It is also readily soluble in alcohol. When exposed to a low red heat it melts, and at bright redness is volatilized. On account of its deliquescent property, and its strong attraction for carbonic acid, it requires to be kept in very accurately stopped bottles. In the state here described, the alkali always contains combined water as a part of its composition. As obtained by the U. S., London, and Edinburgh formulæ, it contains various impurities, which, however, do not interfere with its medicinal value; such as sulphate of potassa, chloride and teroxide of potassium, sesquioxide of iron, lime, silica, alumina, and a portion of the alkali itself still in a carbonated state. The insoluble impurities, according to the Edinburgh Pharmacopœia, should not exceed 1·25 per cent. The Dublin alkali, being obtained from a solution derived from pure carbonate of potassa, is purer than that of the other Pharmacopœias. Officinal potassa may be rendered nearly pure by digestion in alcohol, which takes up only the hydrated alkali, evaporating the solution to dryness, and fusing the dry mass obtained. *Hydrate of potassa*, when thus procured, is called *alcoholic potassa*. It is generally in the form of flat white pieces, which are dry, hard, brittle, and extremely caustic. Its other properties are similar to those of the impure hydrate above described. According to Mr. H. Wurtz, of New York, alcoholic potassa usually contains a trace of silicate of potassa, which appears to be taken up by the alcohol. The source of this is the carbonate of potassa employed, which may be freed from this impurity by evaporating its aqueous solution, in a sheet-iron dish, to dryness, and adding, from time to time, lumps of carbonate of ammonia. The silicate is thus converted into the carbonate; and, on dissolving the residue, the silica appears in flakes, which may be separated by filtration. (*N. Y. Journ. of Pharm.*, Feb. 1852.) Potassa may be discriminated from the other fixed alkalies (soda and lithia) by affording, when in solution, a crystalline precipitate (cream of tartar) with an excess of tartaric acid, and a yellow one with chloride of platinum. The officinal potassa, apart from impurities, consists of one eq. of dry potassa 47·2 and one of water 9=56·2. Dry potassa is composed of one eq. of potassium 39·2, and one of oxygen 8=47·2. (See *Potassium.*) B.

Medical Properties and Uses. This is the old *causticum commune acerrimum*, or *strongest common caustic*. It is a very powerful escharotic, quickly destroying the life of the part with which it comes in contact, and extending its action to a considerable depth beneath the surface. In this latter respect, it differs from the nitrate of silver or lunar caustic, to which it is, therefore, preferred for the purposes of forming issues and opening abscesses. It has been used for removing stricture of the urethra; but, in consequence of its tendency to spread, it may, unless carefully applied, produce such a destruction of the lining membrane, as to open a passage for the urine into the cellular tissue, and thus involve the patient in danger. The most convenient mode of employing the caustic for the formation of an issue, is to apply to the skin a piece of linen spread with adhe-

sive plaster, having a circular opening in its centre corresponding with the intended size of the issue, and then to rub upon the skin, within the opening, a piece of the caustic previously moistened at one end. The application is to be continued till the life of the part is destroyed, when the caustic should be carefully washed off with a wet sponge or wet tow, or neutralized by vinegar. The preparation is also employed for forming solutions of potassa of definite strength, whether for medicinal or pharmaceutic use. A solution of one drachm and a half of caustic potassa in two fluidounces of distilled water, was highly recommended by the late Dr. Hartshorne, of Philadelphia, as an application to the spine in tetanus. It may be applied by means of a sponge attached to the end of a stick, which should be drawn quickly along the back from the nape of the neck to the sacrum. It produces a very powerful rubefacient effect.

The U. S. Pharmacopœia employs caustic potassa in the preparation of Ether, and of Black Oxide of Mercury.

Off. Prep. Potassa cum Calce; Potassii Iodidum. W.

POTASSA CUM CALCE. *U. S., Lond., Ed.* Potassa Caustica cum Calce. *Dub. Potassa with Lime.*

"Take of Potassa, Lime, each, *an ounce.* Rub them together, and keep the mixture in a well stopped bottle." *U. S.*

The *London* and *Dublin* formulæ are the same as the above.

"Take *any convenient quantity* of Aqua Potassæ; evaporate it in a clean, covered iron vessel to one-third of its volume; add slaked Lime till the fluid has the consistence of firm pulp. Preserve the product in carefully covered vessels." *Ed.*

The U. S., London, and Dublin preparation is a mixture of equal parts of hydrate of potassa and lime. The Edinburgh College employs the solution of potassa, which is first concentrated, and then thickened by the addition of lime until the mixture becomes a pulpy mass, consisting of the mixed hydrates of potassa and lime.

The U. S., London, and Dublin preparation is a powder, sometimes called *Vienna caustic.* It is prepared for use by being made up into a paste with a little alcohol. The paste is applied to the part to be cauterized for ten or fifteen minutes, and is conveniently limited in its operation by a piece of adhesive plaster, in the manner explained under potassa. The Edinburgh preparation is in the form of a firm pulp, formerly called *causticum commune mitius*, or *milder common caustic.* Potassa with lime is a more manageable caustic than the officinal potassa, on account of the presence of the lime, which renders it milder, slower in its operation, and less deliquescent, and causes it to spread less beyond the part intended to be affected. Dr. Filhos has improved this caustic by forming it in sticks. To prepare it thus, the potassa is perfectly fused in an iron spoon, and one-third of its weight of quicklime is added in divided portions; the whole being stirred with an iron rod. The fused mass is then run into lead tubes, closed at one end, about three inches long, and from a quarter to half an inch in diameter in the clear. The sticks are kept, still enclosed in the lead tubes, with the open end downwards, in thick glass tubes, containing some powdered quicklime, and closed with a cork, between which and the stick some cotton is put to steady the caustic. When employed, as much of the caustic is uncovered at the end, by scraping off the lead, as it is proposed to use. This form of caustic is particularly recommended for cauterizing the neck of the uterus. (*Journ. de Pharm.*, 3e *sér.*, vi. 137.) B.

POTASSÆ ACETAS. *U. S., Lond., Ed., Dub. Acetate of Potassa.*

"Take of Acetic Acid *a pint;* Carbonate of Potassa *a sufficient quantity.*

Add the Carbonate of Potassa gradually to the Acetic Acid till it is saturated; then filter, and evaporate cautiously, by means of a sand-bath, until a dry salt remains. Keep this in closely stopped bottles." *U. S.*

"Take of Acetic Acid *twenty-six fluidounces* [Imp. meas.]; Carbonate of Potassa *a pound*, or *a sufficient quantity;* Distilled Water *twelve fluidounces* [Imp. meas.]. To the Acid, mixed with the Water, gradually add the Carbonate to saturation; then strain. Evaporate the liquor in a sand-bath, with a heat cautiously applied, until the salt is dried." *Lond.*

"Take of Pyroligneous Acid [acetic acid, sp. gr. 1·034] *a pint and a half* [Imp. meas.]; Carbonate of Potash (dry) *seven ounces* or *a sufficiency.* Add the Carbonate gradually to the Acid till complete neutralization is accomplished. Evaporate the solution over the vapour-bath till it is so concentrated as to form a concrete mass when cold. Allow it to cool and crystallize in a solid cake; which must be broken up and immediately put into well closed bottles." *Ed.*

"Take of Pure Carbonate of Potash *one pound* [avoirdupois]; Acetic Acid of Commerce (sp. gr. 1·044) *two pints* [Imp. meas.]. To the Acid, placed in a porcelain capsule, gradually add the Carbonate of Potash, and, when effervescence has ceased, boil for a couple of minutes. Add now, if necessary, a few drops of the same Acetic Acid, so that the solution may have a slightly acid reaction; and, having evaporated to dryness, melt the residue, by the cautious application of heat, in a clean pot of cast iron. The liquefied salt is now to be removed from the fire, and when, upon cooling, it has solidified, it should be quickly broken into fragments of a suitable size, and enclosed in a bottle, furnished with an air-tight stopper." *Dub.*

The process for forming acetate of potassa is a case of single elective affinity. The form of acid employed for generating the salt in the several Pharmacopœias is officinal acetic acid; the pyroligneous acid of the Edinburgh College being equivalent to that acid. Distilled vinegar should never be employed to form this salt, on account of its containing organic matter, which gives the solution, when concentrated, a reddish or brownish colour. When acetic acid is used a colourless solution is obtained. This is evaporated to dryness, according to the U. S. and London Pharmacopœias, and to such an extent as to concrete into a mass when cold, according to the Edinburgh. The Dublin College fuses the dry salt, and obtains it as a solid mass on cooling. When fusion is resorted to, great care must be taken not to use too high a heat; otherwise part of the acetic acid will be decomposed, and a colourless salt will not be obtained. For drying the acetate of potassa, Dr. Christison considers the heat of a vapour-bath too low, and that of a sand-bath apt to become too high. He, therefore, recommends the use of a bath of chloride of calcium, when operating on a small scale. In conducting the evaporation, it is best to have the solution always slightly acid; for if the alkali predominate, it will react upon the acetic acid when the solution is concentrated, and give rise to discoloration.

Acetate of potassa may also be obtained by double decomposition between acetate of lead and sulphate of potassa. When thus procured it is very white and pure, but liable to the objection, for medical use, that it may possibly contain a little lead. Another method by double decomposition is between acetate of lime and sulphate of potassa.

Properties, &c. Acetate of potassa when pure is a white salt, perfectly neutral to test paper, unctuous to the touch, and of a warm, pungent, saline taste. When unskilfully prepared, it is apt to be more or less coloured. Its state of aggregation differs with the manner in which it is prepared. As obtained by evaporating the solution to dryness, agreeably to the directions of the U. S. and London Pharmacopœias, it is in the form of soft fibrous masses. As usually prepared and found in the shops, it has a foliated texture, which is given to it

by fusion and cooling. On account of this appearance it was formerly called *foliated earth of tartar*. This salt is extremely deliquescent, and, if exposed to the air, becomes converted into a liquid of an oleaginous appearance. It is on account of this property that it must always be preserved in well stopped bottles. It dissolves in about half its weight of water, and twice its weight of alcohol. Anything remaining undissolved by these menstrua is impurity. Heated above its point of fusion it is decomposed into acetone and carbonate of potassa; the acetic acid being resolved into this volatile liquid and carbonic acid. When treated with sulphuric acid, acetous vapours are copiously evolved, and sulphate of potassa is formed. One hundred grains of the salt, decomposed by sulphuric acid, furnish a salt (sulphate of potassa), which, after exposure to a strong heat, weighs 88·8 grains. (*Lond. Pharm.*) The most usual impurities contained in it are sulphate and tartrate of potassa, chloride of potassium, and the salts of lead and copper. A soluble sulphate may be detected by chloride of barium; and chloride of potassium, or any soluble chloride, by nitrate of silver added to a *dilute* solution. If the nitrate be added to a concentrated solution, crystals of acetate of silver will be precipitated, soluble in water or dilute nitric acid. With chloride of platinum it yields a yellow precipitate, showing it to be a salt of potassa. If tartrate of potassa be present, it will remain undissolved when the salt is acted on by alcohol. Lead and copper may be detected by sulphuretted hydrogen and ferrocyanuret of potassium; the former test producing with the lead a blackish, and the latter with the copper a brown precipitate. Since the introduction of the cheap method of obtaining pure acetic acid from wood, this salt has scarcely been subject to adulteration. Acetate of potassa is incompatible with the mineral acids, which expel the acetic acid; with sulphate of soda and sulphate of magnesia; with corrosive sublimate and nitrate of silver; and with several other earthy and metallic salts. This salt exists in the juices of many plants, and especially in the sap of trees, and is the principal source of the carbonate of potassa existing in the ashes of wood. It consists of one eq. of acetic acid 51, one of potassa 47·2, and two of water 18=116·2.

Medical Properties and Uses. Acetate of potassa acts as a diuretic in doses of from a scruple to a drachm, and as a mild cathartic when given to the extent of two or three drachms. It is employed in dropsies, and often with good effect. The late Dr. Duncan considered it to be a medicine of great efficacy, and one of our best saline deobstruents. We have ourselves used it in dropsical affections, and can bear testimony to its powers. Dr. J. A. Easton, of Glasgow, has found it a useful remedy in several skin diseases, such as psoriasis, eczema, and lepra. Cases which had resisted the ordinary remedies were cured, after a treatment occupying from three weeks to two months. The dose given by Dr. Easton was half a drachm, three times a day, dissolved in water. The remedy seemed to act through the kidneys, the urine being remarkably increased, both in its aqueous and solid contents. (*Edin. Month. Journ. of Med. Sci.*, May, 1850.) The salt, equally efficacious, may be made extemporaneously in the liquid form by saturating distilled vinegar with carbonate of potassa. Two drachms of the carbonate, saturated with vinegar, will sometimes produce in hydropic cases ten or twelve stools, and a copious discharge of urine. (*Duncan.*) Acetate of potassa, like the other alkaline salts containing a vegetable acid, may be given in the uric acid diathesis, to render the urine alkaline; for the experiments of Wöhler have shown that the acid of these salts undergoes decomposition in the digestive and assimilating processes, while the alkali enters the current of the circulation. From the decided property which this salt possesses of increasing the secretion of the kidneys, it was formerly called *sal diureticus*, or *diuretic salt*.

POTASSÆ CARBONAS. *U. S.*, *Lond.*, *Ed.* POTASSÆ CARBONAS E LIXIVO CINERE. *Dub.* *Carbonate of Potassa.* *Carbonate of Potassa from Pearlash.*

"Take of Impure Carbonate of Potassa [pearlash] *three pounds;* Water *two pints and a half.* Dissolve the Impure Carbonate of Potassa in the Water, and filter the solution; then pour it into a clean iron vessel, and evaporate over a gentle fire till the solution thickens; lastly, remove it from the fire, and stir it constantly with an iron spatula till the salt granulates." *U. S.*

The *London College*, in its Pharmacopœia of 1851, has placed this salt in the Materia Medica list. The Edinburgh College also includes it in the Materia Medica list, designating it by this note. "Carbonate of potash not quite pure, obtained by lixiviating, evaporating, and granulating by fusion and refrigeration the potashes [pearlash] of commerce."

"Take of Pearlash *ten pounds* [avoirdupois]; Distilled Water *one gallon* [Imp. meas.]. Pour the Water on the Pearlash, and macerate for a week, occasionally stirring the mixture. Filter through calico, and, having evaporated the solution nearly to dryness, reduce the heat, and stir constantly with an iron rod, until granular crystals are obtained. Let these be immediately enclosed in well stopped bottles." *Dub.*

The object of the above processes is to purify the impure carbonate of potassa, or pearlash. This generally contains certain insoluble impurities, as well as small portions of sulphate and silicate of potassa, and chloride of potassium, as explained under another head. (See *Potassæ Carbonas Impurus.*) By dissolving it in a due proportion of water, and filtering the solution, the insoluble impurities are got rid of, as well as the greater part of the foreign salts, which, being much less soluble than the carbonate of potassa, are excluded by the superior affinity of this salt for the water. The proper way of conducting the purification is to mix the impure carbonate with an equal weight of *cold* water, and to allow the mixture to stand for a day or two, stirring it frequently to promote the action of the water. The clear liquor obtained by decantation or filtration is then evaporated to dryness. The officinal processes are conducted very much in this way; cold water being employed, and equal weights of alkali and water being used in the Dublin formula, and about equal weights in the process of the U. S. Pharmacopœia. The prolonged contact of the water with the salt, and the occasional stirring of the mixture, ordered by the Dublin College, are useful directions. In no case should the undissolved residue be washed with a fresh portion of water; as, by such a proceeding, the foreign salts, which it is the object of the process to separate, would be dissolved. Iron vessels are directed, because this metal is not acted on by the alkali, while glass is attacked by it. In granulating the salt by stirring, it is better, when the solution is brought nearly to dryness, to keep it on the fire at a reduced heat, as recommended by the Dublin College, until the process is finished, than to remove it the moment it thickens.

According to Berzelius, a more productive process for purifying pearlash, though the resulting salt is not so pure as when obtained in the way just described, is to dissolve the pearlash in more than its weight of water, to evaporate the solution till it has the density of 1·52, and then to put it in a cool place, that the foreign salts, principally sulphate of potassa and chloride of potassium, may crystallize. The solution is then decanted, and evaporated to dryness.

Properties, &c. Carbonate of Potassa, as found in the shops, is in the form of a coarse granular white powder, having a nauseous, alkaline taste, and acting as an alkali on vegetable colours. It is very soluble in water, dissolving in its weight of that liquid; but is insoluble in alcohol. It is extremely deliquescent, and hence a portion of it, exposed to the air for some time, attracts so much water as completely to dissolve into an oily liquid, called by the older chemists,

oleum tartari per deliquium. On account of this property, carbonate of potassa should be kept in bottles with accurately ground stoppers. If exposed, in its usual state, to a red heat, it retains its carbonic acid, but loses 16 per cent. of water; and, when decomposed by dilute sulphuric acid, evolves 26·3 per cent. of carbonic acid. (*Lond. Pharm.*) When pure it is completely soluble in water; but, generally, a small insoluble portion is left of earthy matter. An aqueous solution, when saturated with an acid, slowly deposits a slight gelatinous precipitate, derived from silica. The usual impurities are earthy matter, sulphate of potassa, chloride of potassium, and silica in the state, probably, of silicate of potassa. When dissolved in water and supersaturated with nitric acid, it affords a faint cloudiness with chloride of barium, and a slight precipitate with nitrate of silver; effects showing the presence of minute portions of a sulphate and of a chloride. The nitric solution is also precipitated by carbonate of soda, if earthy matter be present. If the indications of these tests are decided, the salt is below the officinal standard of purity. It is incompatible with acids and acidulous salts, muriate and acetate of ammonia, lime-water, chloride of calcium, sulphate of magnesia, alum, tartar emetic, nitrate of silver, ammoniated copper and ammoniated iron, sulphate of iron and tincture of chloride of iron, calomel and corrosive sublimate, acetate and subacetate of lead, and sulphate of zinc. It is not decomposed by tartrate of iron and potassa, and, therefore, may be associated with it in prescriptions.

Composition. Carbonate of potassa, after exposure to a red heat, is an anhydrous salt, consisting of one eq. of carbonic acid 22, and one of potassa 47·2 = 69·2. As obtained by the officinal formulæ, it is, according to Mr. Phillips, a sesquihydrate, consisting of two eqs. of carbonate and three of water. B.

Medical Properties and Uses. Purified pearlash is the form of carbonate of potassa usually employed in this country, where it is frequently, though incorrectly, called *salt of tartar*, the latter name being strictly applicable to the purer carbonate, obtained by decomposing cream of tartar. It is occasionally used as an antacid in dyspepsia, as a diuretic in dropsy, and as an antilithic in gravel attended with red deposits from the urine; but the purpose to which it is most commonly applied is the formation of the *neutral mixture* and *effervescing draught.* (See *Liquor Potassæ Citratis.*) It is worthy of observation, that its solution, on exposure to air, or on the addition of an acid, deposits flocculi consisting of hydrate of silica, resulting from the decomposition of the silicated potassa, which is always present as an impurity. The spontaneous deposition of silica is owing to the absorption of carbonic acid. Carbonate of potassa is also used with much advantage in some cases of jaundice, in which it probably operates by entering the circulation, and directly exciting the hepatic function. It has enjoyed some popular reputation mixed with cochineal in hooping-cough, and is supposed by some, in common with other alkaline remedies, to operate favourably in those inflammations in which there is a disposition to the exudation of coagulable lymph, or the formation of false membranes. It is considered among the most effectual remedies in obstinate cutaneous eruptions, in which it is employed both internally and externally. The dose is from ten to thirty grains, given in some aromatic water sweetened with sugar. In large quantities it acts as a corrosive poison, and is capable of producing death in a few hours. The antidotes are the fixed oils and vegetable acids.

As an external remedy in cutaneous affections, it is used in the form of bath, of lotion, and of ointment. From eight to sixteen ounces may be used for a single bath, the quantity being gradually increased. Lotions may be made by dissolving two or three drachms in a pint of water; and ointments by rubbing from ten grains to a drachm with an ounce of lard.

Carbonate of Potassa is used in the formulæ for Precipitated Sulphuret of Antimony, and Spirit of Nitric Ether.

POTASSÆ CARBONAS PURUS. *U. S.* POTASSÆ CARBONAS PURUM. *Ed., Dub. Pure Carbonate of Potassa. Salt of Tartar.*

"Take of Bicarbonate of Potassa *a pound.* Put the Bicarbonate, previously powdered, into a capacious iron crucible, heat gradually until the water of crystallization is driven off, then raise the heat to redness, and maintain that temperature for half an hour. Having taken the crucible from the fire, and allowed it to cool, remove its contents, dissolve them in distilled water, filter the solution, and complete the process by evaporating and granulating as directed for Carbonate of Potassa." *U. S.*

"Pure Carbonate of Potash may be most readily obtained by heating crystallized Bicarbonate of Potash to redness in a crucible; but more cheaply by dissolving Bitartrate of Potash in thirty parts of boiling Water, separating and washing the crystals which form on cooling, heating these in a loosely covered crucible to redness so long as fumes are discharged, breaking down the mass, and roasting it in an open crucible for two hours, with occasional stirring, lixiviating the product with Distilled Water, filtering the solution thus obtained, evaporating the solution to dryness, granulating the salt towards the close by brisk agitation, and heating the granular salt nearly to redness. The product of either process must be kept in well closed vessels." *Ed.*

"Take of white Bitartrate of Potash *two pounds* [avoirdupois]; Sesquicarbonate of Ammonia *half an ounce* [avoird.]; Distilled Water *three pints* [Imp. meas.]. Place the Bitartrate of Potash in an iron pot or crucible, and, constantly stirring it with an iron rod, expose it to a red heat until vapours cease to be evolved. Reduce the residuum to a coarse powder, and having boiled it for twenty minutes with one quart [two pints, Imp. meas.] of the Water, filter through paper, washing the filter and its contents with the residual pint of Water, in which the Sesquicarbonate of Ammonia has been first dissolved. The filtered solution is now to be evaporated to dryness, and, a low red heat being finally applied, the product is to be rapidly reduced to powder in a warm mortar, and enclosed in well-stopped bottles." *Dub.*

In the *U. S.* process for pure carbonate of potassa, the bicarbonate is ignited, whereby it loses its water of crystallization, and second equivalent of carbonic acid, and is reduced to the state of carbonate. As the bicarbonate is a very pure salt, so the carbonate, obtained from it, is also very pure.

The first process of the *Edinburgh* College is the same as the above; the second directs the pure carbonate to be obtained from bitartrate of potassa, by first purifying it by solution and crystallization, and then incinerating it. The tartaric acid, which consists of carbon, hydrogen, and oxygen, is decomposed, and gives rise, among other products, to carbonic acid, which combines with the potassa. The matter, after ignition, contains, besides carbonate of potassa, certain impurities derived from those pre-existing in the bitartrate. These are carbonate of lime, arising from the decomposition of tartrate of lime, alumina, silica, and minute portions of the oxides of iron and manganese; and, being all insoluble in water, are left behind when the mass is acted on by that liquid, the alkaline carbonate alone being taken up. The Dublin process is the same as the second Edinburgh, with the additional step of washing the filter and its contents with

a solution of sesquicarbonate of ammonia. This addition to the filtered solution of the carbonate of potassa supplies any deficiency in its carbonic acid which may have been caused by the previous ignition; while, by the evaporation to dryness, and final exposure to a low red heat, the whole of the ammonia is dissipated.

Properties, &c. Pure carbonate of potassa, obtained from the bicarbonate or from cream of tartar, differs from the same salt procured from pearlash, in containing no impurities. With the tests mentioned under the carbonate it gives negative indications, showing the entire absence of foreign substances. When obtained from cream of tartar, it was formerly called *salt of tartar*, in allusion to its source; but at present this name is usually applied to any pure carbonate of potassa, without reference to its mode of preparation. It may, indeed, be very much doubted whether the real salt of tartar is often kept in our shops; the ordinary carbonate as purified from pearlash being generally substituted for it, and answering, in ordinary cases, every medicinal purpose that could be expected from the use of the purer salt.

Medical Properties and Uses. These are the same with those of the carbonate of potassa described in the preceding article. The pure carbonate, on account of its freedom from silica, furnishes the best material for forming the solution of citrate of potassa, or neutral mixture.

LIQUOR POTASSÆ CARBONATIS. *U. S.*, *Lond.* POTASSÆ CARBONATIS LIQUOR. *Dub.* *Solution of Carbonate of Potassa.*

"Take of Carbonate of Potassa *a pound;* Distilled Water *twelve fluidounces.* Dissolve the Carbonate of Potassa in the Water, and filter the solution." *U. S.*

"Take of Carbonate of Potassa *twenty ounces;* Distilled Water *a pint* [Imp. meas.]. Dissolve and filter. The specific gravity is 1·473." *Lond.*

"Take of Pure Carbonate of Potash *ten ounces* [avoirdupois]; Distilled Water *one pint* [Imp. meas.]. Dissolve and filter. The specific gravity of this solution is 1·310." *Dub.*

This is a solution of carbonate of potassa in water, and furnishes a convenient form for the administration of the salt. An ounce is dissolved in a fluidounce of water in the U. S. formula, and in an Imperial fluidounce in the London. In the Dublin solution, half an ounce avoirdupois is dissolved in an Imperial fluidounce. This statement in relation to the British solutions will be understood, when the fact is adverted to that the Imperial pint contains twenty fluidounces. The London solution is somewhat stronger than that of the U. S. Pharmacopœia, because the Imperial fluidounce weighs a little less than a fluidounce, wine measure. The Dublin process differs in using the pure carbonate, and in furnishing a solution considerably less than half as strong as the U. S. and London solutions. Solution of carbonate of potassa should be colourless and inodorous, and possess the general alkaline qualities of the salt from which it is made. The dose of the U. S. or London solution is from ten minims to a fluidrachm, sufficiently diluted with water or other bland liquid. B.

POTASSÆ BICARBONAS. *U. S.*, *Lond.*, *Ed.*, *Dub.* *Bicarbonate of Potassa.*

"Take of Carbonate of Potassa *four pounds;* Distilled Water *ten pints.* Dissolve the Carbonate of Potassa in the Water, and pass carbonic acid through the solution till it is fully saturated. Then filter, and evaporate the filtered liquor that crystals may form, taking care that the heat does not exceed 160°. Pour off the supernatant liquid, and dry the crystals upon bibulous paper. Carbonic acid is obtained from Marble by the addition of dilute sulphuric acid." *U. S.*

In the London Pharmacopœia of 1851, bicarbonate of potassa is placed in the list of the Materia Medica.

"Take of Carbonate of Potash from Pearlash *one pound* [avoirdupois]; Distilled Water *one quart* [two pints, Imp. meas.]; Muriatic Acid of Commerce *one pint and a half* [Imp. meas.]; Water *three pints* [Imp. meas.]; Chalk, in small fragments, *one pound* [avoird.], or *a sufficient quantity*. Dilute the Muriatic Acid with the Water, and having dissolved the Carbonate of Potash in the *Distilled* Water, filter the solution into a three-pint bottle, capable of being tightly closed by a cork, traversed by a glass tube sufficiently long to pass to the bottom of the solution. A second bottle, in the bottom of which a few holes are drilled, and the mouth of which admits of being closed by a cork, also traversed by a glass tube, having been filled with the Chalk, and placed in a glass or porcelain jar of the same height with itself, but of somewhat larger diameter, the exterior ends of the two tubes are to be connected *air-tight* by a tube of vulcanized Indian rubber. The cork of the bottle containing the Carbonate of Potash being placed *loosely*, and that of the other bottle tightly in its place, and the Muriatic Acid having been poured into the jar in which is lodged the perforated bottle containing the Chalk, the liberation of carbonic acid commences, and as soon as it is judged that a sufficient amount of it has been developed to expel completely the air from the apparatus, the cork of the Carbonate of Potash bottle is to be forced into it quite tight, and the process is to be abandoned to itself for a week. At the end of this time numerous crystals of the Bicarbonate of Potash will have formed, which are to be removed, shaken in a capsule with twice their bulk of cold water, which is to be rapidly decanted, next drained, and finally dried on bibulous paper by mere exposure to the atmosphere. The mother liquor, if filtered, and concentrated to one-half, at a temperature not exceeding 110°, will yield additional crystals. The tube immersed in the solution of Carbonate of Potash will have to be occasionally cleared of the crystals with which it is liable to become plugged, else the process will be suspended." *Dub.*

"Take of Carbonate of Potash *six ounces;* Carbonate of Ammonia *three ounces and a half.* Triturate the Carbonate of Ammonia to a very fine powder; mix it with the Carbonate of Potash; triturate them thoroughly together, adding by degrees a very little water, till a smooth and uniform pulp be formed. Dry this gradually at a temperature not exceeding 140°, triturating occasionally towards the close; and continue the desiccation till a fine powder be obtained, entirely free of ammoniacal odour." *Ed.*

In these processes, the carbonate of potassa, consisting of one eq. of acid and one of base, is combined with an additional equivalent of carbonic acid. In the U. S. and Dublin processes the combination is effected by passing a stream of this acid through a solution of the carbonate, so long as it is absorbed. In the U. S. formula the distilled water taken is about three times the weight of the carbonate. As the bicarbonate of potassa requires four times its weight of water to dissolve it, the quantity of water ordered in the U. S. formula would seem not to be sufficient to dissolve the new salt; unless it be assumed that the solution becomes heated in consequence of the reaction. The solution of the whole of the new salt is not intended in the Dublin process, which proceeds on the plan of forming crystals of bicarbonate at once in the original solution, without concentration by heat. The filtration directed in the U. S. formula is ordered on the presumption that the whole of the bicarbonate formed is dissolved; and is intended to separate silica, which is always deposited during the progress of the saturation, when carbonate of potassa from pearlash is employed. On a small scale the saturation of the carbonate is best conducted in a Wolfe's apparatus of three bottles; the first containing water to wash the carbonic acid gas, the two others, solutions of the carbonate. The bottles should be connected by means

of wide tubes, to prevent their being obstructed by the crystals formed. On a large scale the saturation is performed in strong vessels, into which the carbonic acid is driven under pressure. Sulphuric acid is always used by the manufacturing chemist for generating the carbonic acid; but in small operations, muriatic acid, diluted with twice its bulk of water, is more convenient; inasmuch as it generates with the marble or chalk a soluble salt (chloride of calcium), which does not interfere with the extrication of the carbonic acid, as the insoluble sulphate of lime does. In the Dublin process dilute muriatic acid is used for the extrication of the carbonic acid, which is effected in a self-regulating generator of that gas.

In the Edinburgh process, carbonate of ammonia, in very fine powder, is thoroughly incorporated with carbonate of potassa, by the assistance of a little water, so as to form a uniform pulp, which is dried by a gentle heat. By the combined influence of the volatility of the ammonia, and the affinity of the carbonate of potassa for carbonic acid, the carbonate of ammonia is totally decomposed; its carbonic acid generating the bicarbonate by uniting with the carbonate, and its ammonia being evolved during the drying of the pulp, which is then reduced to a fine powder. This process is alleged by Dr. Christison to be superior to the other process, "in point of economy, dispatch, and certainty in small operations."

Mr. Brande gives the following proportions for the preparation of bicarbonate of potassa on the large scale: "100 lbs. of purified carbonate of potassa are dissolved in 17 gallons of water, which, when saturated with carbonic acid, yield from 35 to 40 lbs. of crystallized bicarbonate; 50 lbs. of carbonate of potassa are then added to the mother liquor, with a sufficient quantity of water to make up 17 gallons, and the operation repeated."

Wöhler states that charcoal, when mixed with the carbonate, facilitates by its porosity, in a remarkable degree, the formation of the bicarbonate. Thus he found that when crude tartar was charred in a covered crucible, and the carbonaceous mass, after having been slightly moistened with water, was subjected to a stream of carbonic acid, the gas was absorbed with great rapidity, and heated the mass so considerably, as to render it necessary to surround the vessel with cold water, to prevent the decomposition of the bicarbonate that had been formed. When the temperature diminished, the saturation was known to be completed. The mass was lixiviated in the smallest quantity of water at the temperature of from 85° to 100°, and the solution, after filtration and cooling, deposited the greater part of the bicarbonate in fine crystals. (*Am. Journ. of Pharm.*, x. 82, from the *Annalen der Physik und Chemie.*)

M. Behrens has proposed to obtain bicarbonate of potassa by partially saturating the carbonate, dissolved in an equal weight of water, with acetic acid gradually added. Up to a certain point, no carbonic acid is extricated, and a precipitate takes place of pure bicarbonate of potassa, equal to half the weight of the carbonate employed. After the bicarbonate is separated, the saturation may be completed, and acetate of potassa obtained. (*Journ. de Pharm.*, 3e *sér.*, iv. 464.) A similar production of the bisalt takes place when the carbonate is treated with weak lemon-juice, in forming the citrate. (See *page* 1144.)

According to Berzelius, the cheapest method of obtaining the bicarbonate of potassa is to suspend a concentrated solution of the purified carbonate, contained in a stoneware dish, within a cask over a liquid undergoing the vinous fermentation. The alkali is thus surrounded by an atmosphere of carbonic acid, and, by absorbing it, crystallizes into bicarbonate in the course of five or six weeks. Distillers and brewers prepare this salt with great facility by suspending the alkaline solution in the fermenting tun. The salt in powder called *sal aëratus*, made principally in New England, is, we believe, prepared in this way. In composition it is between a carbonate and bicarbonate.

Properties, &c. Bicarbonate of potassa is in transparent, colourless, inodorous crystals, slightly alkaline to the taste and to test paper, permanent in the air, and having the shape of irregular eight-sided prisms with two-sided summits. It dissolves in four times its weight of cold water, and in five-sixths of its weight of boiling water, by which it is partially decomposed, and converted into *sesquicarbonate.* It is insoluble in alcohol. Exposed to a red heat, it loses 30·7 per cent., comprising half its carbonic acid and the whole of its water of crystallization, and returns to the state of carbonate, which, when thus obtained, is free from silica, and otherwise very pure. This method is now adopted in the U. S. Pharmacopœia for obtaining the pure carbonate, and forms the first process of the Edinburgh. Supersaturated with nitric acid, it should give a clear solution, the transparency of which is not disturbed by chloride of barium, and but slightly by nitrate of silver. When a perfect bicarbonate, its solution, unless heated, does not precipitate a solution of sulphate of magnesia. This negative indication, however, cannot be depended upon as showing the absence of carbonate; for, according to Dr. Christison, no precipitate will be occasioned, even when fifty per cent. of this impurity is present. Bicarbonate of potassa does not decompose calomel. When dissolved in 40 parts of water, it produces a white haze merely with a solution of corrosive sublimate; but if it contain so little as a hundredth part of carbonate, a brick-red precipitate is immediately produced. (*Christison.*) Another way of detecting the presence of carbonate is to add starch sugar to a heated solution of the suspected bicarbonate. If any carbonate be present, the mixture turns yellow or brown. (*Chevallier.*) Bicarbonate of potassa consists of two eqs. of carbonic acid 44, one of potassa 47·2, and one of water 9=100·2.

Medical Properties. The medical properties of this salt are the same as those of the carbonate, to which it is preferable from its milder taste, and greater acceptability to the stomach. The dose is from twenty grains to a drachm.

Off. Prep. Liquor Potassæ Citratis; Potassæ Aqua Effervescens; Potassæ Carbonas Purus; Potassæ Citras; Pulveres Effervescentes; Pulveres Effervescentes Citrati. B.

POTASSÆ AQUA EFFERVESCENS. *Ed. Effervescing Water of Potassa.*

"Take of Bicarbonate of Potash *one drachm;* Distilled Water *one pint* [Imp. meas.]. Dissolve the Salt in the Water, and transmit through the solution carbonic acid gas under strong pressure." *Ed.*

This preparation may be considered as the bicarbonate of potassa dissolved in carbonic acid water. It is, however, altogether superfluous in this country, in consequence of the general introduction into the shops of carbonic acid water (artificial Seltzer water), which may be readily employed for dissolving any desired proportion of the bicarbonate, with the result of forming a much brisker preparation. This solution has the general sparkling qualities and acidulous taste of carbonic acid water; the alkaline taste being covered in a great measure by the large excess of carbonic acid. The after-taste is more purely saline than that of the corresponding preparation made with soda. (See *Sodæ Aqua Effervescens.*) B.

POTASSÆ CITRAS. *U. S. Citrate of Potassa.*

"Take of Citric Acid *ten ounces;* Bicarbonate of Potassa *fourteen ounces;* Water *a sufficient quantity.* Dissolve the Citric Acid in two pints of Water, add the Bicarbonate gradually, and, when effervescence has ceased, strain, and evaporate to dryness, stirring constantly, after a pellicle has begun to form, until the salt granulates; then rub it in a mortar, pass it through a coarse sieve, and put it in bottles, which should be kept closely stopped." *U. S.*

Citrate of potassa has long been used habitually in this country for the preparation of the neutral mixture, but was first recognised as officinal in the U. S. Pharmacopœia of 1850. It was known formerly by the name of *salt of Riverius.* In the above formula, mutually saturating proportions of the acid and bicarbonate were intended to be employed; the latter ingredient being preferred to the carbonate on account of its greater purity. The potassa of the bicarbonate unites with the citric acid, to form the citrate of potassa, and the carbonic acid escapes, producing effervescence. The resulting solution is directed to be evaporated to dryness, as affording the most convenient form for use. The granulation ordered has a tendency to retard the deliquescence of the citrate.

Citrate of potassa is crystallizable; but, as procured by the above process, is in the form of a white granular powder. It is inodorous, of a saline, slightly bitterish, not unpleasant taste, deliquescent, very soluble in water without residue, and insoluble in alcohol. It is stated in the U. S. Pharmacopœia that its solution does not change the colour of litmus; but we have found a carefully prepared specimen slightly to redden the paper; and the acid used in the process is theoretically in slight excess. By a red heat with exposure to the air, the salt is decomposed, leaving a residue of pure carbonate of potassa. The presence of tartaric acid would be indicated by a precipitate of bitartrate of potassa on the addition of muriatic acid.

Medical Properties. This salt is a grateful refrigerant diaphoretic, and has long been much used in the fevers of this country, in the extemporaneous forms of neutral mixture and effervescing draught. (See *Liquor Potassæ Citratis.*) As these require time and a somewhat careful manipulation in their preparation, it has been found more convenient to keep the citrate of potassa ready made, and dissolve it in water when wanted for use. This solution will no doubt produce the essential diaphoretic and refrigerant effects of the neutral mixture or effervescing draught, but is less agreeable to the stomach and palate, because destitute of the carbonic acid contained in the latter. The dose of this solution is half a fluidounce, of the dry citrate from twenty to twenty-five grains. The preparation may be improved in flavour, and rendered more agreeable to the stomach, by rubbing a drop or two of oil of lemons with the six drachms of citrate before dissolving it, and substituting carbonic acid water for pure water as the menstruum. W.

LIQUOR POTASSÆ CITRATIS. *U. S. Solution of Citrate of Potassa. Neutral Mixture.*

"Take of fresh Lemon-juice *half a pint;* Bicarbonate of Potassa *a sufficient quantity.* Add the Bicarbonate gradually to the Lemon-juice till it is perfectly saturated; then filter. Or,

"Take of Citric Acid *half an ounce;* Oil of Lemons *two minims;* Water *half a pint;* Bicarbonate of Potassa *a sufficient quantity.* Rub the Citric Acid with the Oil of Lemons, and afterwards with the Water till it is dissolved; then add the Bicarbonate of Potassa gradually till the Acid is perfectly saturated; lastly, filter.

"Solution of Citrate of Potassa prepared according to these formulæ contains free carbonic acid, which is deemed a desirable ingredient. It may also be prepared by dissolving six drachms of Citrate of Potassa in half a pint of Water; but, made in this way, contains no carbonic acid." *U. S.*

The first two are equivalent preparations; the solution of citric acid flavoured with oil of lemons being intended as a substitute for fresh lemon-juice when this cannot be had. In both, the potassa of the bicarbonate unites with the citric acid, and the carbonic acid is liberated. A portion of the latter remains in the solution, and a portion escapes with effervescence. The result, therefore, is a solution of citrate of potassa in water impregnated with carbonic acid. When lemon-juice is employed, the solution has a greenish colour; but prepared with

the pure acid it is colourless. In the U. S. Pharmacopœia of 1850, bicarbonate of potassa has been substituted for the carbonate before used. As the preparation was formerly made, a flocculent precipitate was apt to exhibit itself in small quantity, owing to the silicate of potassa generally present as an impurity in the carbonate of potassa. This gave up its base to the citric acid, and the silica was deposited in the state of a hydrate. The bicarbonate is free from this impurity, and consequently hydrated silica is not thrown down; nevertheless, the solution is still directed to be filtered; a direction which may be useful, when fresh lemon-juice is used, by separating the undissolved matters of the juice, and in the other case is only surplusage. About 48 grains of the crystals of the bicarbonate, 33 grains of the pure and perfectly dry carbonate, or 45 grains of the hydrated carbonate found in the shops, are sufficient to saturate a fluidounce of good lemon-juice; but the strength of the juice is variable, and the carbonate is apt to absorb moisture from the air, so that precision as to quantities cannot be readily attained. Hence the propriety of the direction to add the alkaline carbonate to saturation. The point of saturation may be determined by the cessation of effervescence, the absence of either an acid or alkaline taste, and still more accurately by litmus paper, which should not be rendered bright-red by the solution, nor blue if previously reddened by an acid.

The inequality of strength in the lemon-juice renders the neutral mixture prepared with it more or less uncertain; though, if the apothecary select ripe and sound fruit, and express the juice himself, the preparation will be found to approach sufficiently near a uniform standard for all practical purposes. Nevertheless, if the physician wish absolute precision, he may order the neutral mixture to be made with crystallized citric acid as directed in the second officinal formula; or he may pursue the following plan suggested in former editions of this work. Dissolve two drachms of bicarbonate of potassa in two fluidounces of water; saturate the solution with good fresh lemon-juice, and strain; and lastly add enough water to make the mixture measure six fluidounces. A fluidounce of this solution may be given for a dose.

In relation to the preparation of the neutral mixture, by simply dissolving the citrate of potassa in water, as permitted in the third U. S. process above given, see the preceding article, *page* 1143.

Effervescing Draught. Under this name, the citrate of potassa is often prepared extemporaneously, and given in the state of effervescence. The most convenient mode of exhibition is to add to a fluidounce of a mixture consisting of equal parts of lemon-juice and water, half a fluidounce of a solution containing fifteen grains of carbonate of potassa, or twenty grains of the bicarbonate. Should effervescence not occur, as sometimes happens, when the carbonate is used, in consequence of the weakness of the lemon-juice, more of the juice should be added; as, unless sufficient acid is present to neutralize the potassa, part of the carbonate passes into the state of bicarbonate, and the gas is thus prevented from escaping. A solution of citric acid of the strength of that directed in the officinal formula may be substituted for lemon-juice, if this is not to be had. The fifteen grains of carbonate of potassa above mentioned are scarcely sufficient to saturate the lemon-juice, if of ordinary strength; but a little excess of the acid renders the preparation more agreeable to the taste. Some prefer the bicarbonate in the preparation of the effervescing draught, because it will always effervesce with lemon-juice, no matter what may be the strength of the latter. But this is an objection. The carbonate serves, by the absence of effervescence, to indicate when the lemon-juice is very weak in acid; and the defect may then be easily remedied by the addition of more juice. When the bicarbonate is used, if there should be a deficiency of acid, it is not discovered; and the patient takes a considerable portion of undecomposed bicarbonate, instead of the full quantity of citrate intended.

Medical Properties and Uses. The solution of citrate of potassa has long been used under the name of *neutral mixture, saline mixture,* or *effervescing draught.* It is an excellent refrigerant diaphoretic, adapted to almost all cases of fever with a hot dry skin, and especially to the paroxysms of our remittent and intermittent fevers. The *effervescing draught* is peculiarly useful. The carbonic acid serves to cover the taste of the citrate of potassa, and adds to the diaphoretic powers of the salt its own cordial influence over the stomach. No preparation with which we are acquainted is equally efficacious in allaying irritability of stomach, and producing diaphoresis, in our remittent fevers. It is usually also very grateful to the patient. In order to increase the sedative and diaphoretic properties of the neutral mixture, it is customary to add to it a portion of tartar emetic; and a little sweet spirit of nitre will be found an excellent adjuvant in fevers with nervous disturbance. Should the solution irritate the bowels, as occasionally happens, it may be combined with a little laudanum or solution of sulphate of morphia. Sugar may be added if desired by the patient.

The dose of the officinal solution is a tablespoonful or half a fluidounce, which should be somewhat diluted when taken. The whole of each effervescing draught, prepared as above stated, is to be taken at once. Each dose should be repeated every hour, two, or three hours, according to the urgency of the symptoms.

W.

POTASSÆ NITRAS PURUM. *Dub. Pure Nitrate of Potassa.*

"Take of Commercial Nitre *four pounds* [avoirdupois]; Distilled Water *five pints* [Imp. meas.], or *a sufficient quantity.* Having dissolved the Nitre in two pints of the Water at a boiling temperature, let the heat be withdrawn, and the solution be stirred constantly as it cools, in order that the salt may be obtained in very minute crystals. These, deprived as much as possible of the uncrystallized solution by decantation and draining, are to be washed in a glass or earthenware percolator with the remainder of the Water, or until the liquid which trickles through ceases to give a precipitate when dropped into a solution of nitrate of silver. The contents of the percolator should now be extracted, and dried in an oven." *Dub.*

The purified nitre of commerce is sufficiently pure for medicinal use; so that this formula of the Dublin College is entirely unnecessary. The properties of nitre, and the manner in which it is purified, have been fully explained under another head. (See *Potassæ Nitras.*)

B.

POTASSÆ SULPHAS CUM SULPHURE. *Ed. Sulphate of Potassa with Sulphur.*

"Take of Nitrate of Potash and Sulphur *equal parts.* Mix them thoroughly; throw the mixture in small successive portions into a red-hot crucible; and when the deflagration is over, and the salt has cooled, reduce it to powder, and preserve it in well-closed bottles." *Ed.*

When the mixture, indicated in this formula, is thrown into a red-hot crucible, each successive portion melts, and the sulphur floats on the surface with the appearance of a brown oil, burns vividly, and gives rise to a copious evolution of sulphurous acid gas. The product of the deflagration is a grayish-white friable mass, intermixed apparently with undecomposed sulphur.

The nature of this preparation has not been well determined. On the supposition that it is the sulphate of potassa, mixed with a portion of sulphur, as the Edinburgh name implies, its formation may be thus explained. By the combined influence of the sulphur and of the heat employed, the nitric acid of the nitre is totally decomposed, and is thus enabled to furnish sufficient oxygen to convert a portion of the sulphur into sulphuric acid, which, as soon as formed, combines with the base of the nitre, to form the sulphate of potassa. This is

left mixed with a portion of sulphur which has escaped combustion; but the greater part of the latter undergoes ordinary combustion, and is dissipated as sulphurous acid fumes.

Supposing the saline matter to be a sulphate containing a little free sulphur, this combustible is evidently used in great excess; but whether this excess is necessary to obtain the exact preparation desired by the Edinburgh College, it is not easy to determine. The late Dr. Duncan ascertained that the product amounted only to four-tenths of the materials employed. It is, therefore, smaller than it ought to be, even supposing that the residue consisted of nothing but sulphate of potassa.

Dr. Duncan was of opinion that the preparation under consideration cannot be viewed as a sulphuretted sulphate, and for the following satisfactory reasons. In the first place, it is more soluble in water than sulphate of potassa, and forms a yellowish solution, the water leaving undissolved only a small residue of a black colour, which is not sulphur. In the second place, it exhales during solution a sulphurous smell, and its taste is sulphurous. These facts seem to show that a small portion of sulphite of potassa is present in the preparation, or at least some sulphurous acid in loose combination. It does not yield sulphuretted hydrogen on the addition of an acid, and is not precipitated by the salts of lead. These characters are inconsistent with the opinion of Mr. John Mackay, of Edinburgh, that this preparation contains sulphuret of potassium. (See *Pharm. Journ. and Trans.* for Jan. 1842.)

Properties, &c. This salt has an acid and sulphurous taste, and an acid reaction with test paper. When pulverized, it yields a pale yellowish-white powder. It is soluble in eight times its weight of cold water. It is, however, not a uniform preparation; different specimens, apparently prepared with equal care, exhibiting some difference in properties. It was called by the earlier chemists *sal polychrestus Glaseri*, or *sal polychrest.* Its other properties coincide generally with those of sulphate of potassa, which may be considered as its basis.

Medical Properties and Uses. The medical effects of this preparation differ but little, if at all, from those of sulphate of potassa. Its action on the system is stated by Dr. Duncan to resemble that of the sulphurous mineral waters which contain a portion of neutral salt. The dose is from half a drachm to a drachm. B.

POTASSÆ BISULPHAS. *Ed., Dub. Bisulphate of Potassa.*

"Take of the residuum of the preparation of Pure Nitric Acid *two pounds;* Sulphuric Acid (commercial) *seven fluidounces and one fluidrachm* [Imp. meas.]; boiling Water *six pints* [Imp. meas.]. Dissolve the Salt in the Water, add the Acid, concentrate the solution, and set it aside to cool and form crystals." *Ed.*

"Take of Sulphate of Potash, in powder, *three ounces* [avoirdupois]; Pure Sulphuric Acid *one fluidounce* [Imp. meas.]. Place the Acid and Salt in a small porcelain capsule, and to this apply a heat capable of liquefying its contents, and which should be continued until acid vapours cease to be given off. The Bisulphate, which concretes as it cools, should be reduced to a fine powder, and preserved in a well stopped bottle." *Dub.*

In explaining the Edinburgh formula, it is only necessary to recall to the reader's attention a part of the explanations given under the head of *Nitric Acid.* (See *page* 40.) It was there stated that, for the decomposition of nitre on the small scale for the purpose of obtaining nitric acid, it is necessary to use two eqs. of sulphuric acid to one of the salt. Consequently, the salt which remains after the distillation of nitric acid is really a bisulphate, and would seem only to require to be dissolved, and the solution filtered and duly evaporated, in order to obtain the salt in crystals. But Mr. Phillips states that, when the bisulphate of potassa is dissolved in water, and the solution is allowed to crystallize, some

sulphate and much sesquisulphate are obtained instead of bisulphate, owing to the water retaining a part of the excess of acid in solution. This result is prevented by the sulphuric acid directed to be added, and, consequently, the real bisulphate is obtained in crystals. In the process of the *Dublin* College, which is a new one of its Pharmacopœia of 1850, sulphate of potassa is mixed with more sulphuric acid than is necessary to convert it into a bisulphate, and the mixture is exposed to a liquefying heat, which is continued so long as acid vapours continue to be given off. The portion of acid, more than sufficient to form a bisulphate, is thus driven off; so that the saline matter left is the salt under consideration, which, after concreting, is reduced to fine powder.

Properties, &c. Bisulphate of potassa is a white salt, having the form of a right rhombic prism, so flattened as to be tabular, and a bitter and extremely acid taste. It is soluble in twice its weight of cold water, and in less than its weight of boiling water. Alcohol does not dissolve it, but, when added to an aqueous solution, precipitates the neutral sulphate. Exposed to the air, it effloresces slightly on the surface, and when moderately heated readily melts, and runs like oil. At a red heat it loses water and the excess of acid, and is reduced to the state of neutral sulphate. From its excess of acid, it acts precisely as an acid on the carbonates, causing them to effervesce. It is incompatible with alkalies, earths, and their carbonates, with many of the metals, and most oxides. This salt was formerly called *sal enixum.* It consists of two eqs. of sulphuric acid 80, one of potassa 47·2, and two of water 18=145·2.

Medical Properties and Uses. Bisulphate of potassa unites the properties of an aperient with those of a tonic, and may be given in cases of constipation with languid appetite, such as often occur in convalescence from acute diseases. Dr. Paris states that it forms a grateful adjunct to rhubarb. It answers, also, according to Dr. Barker, for preparing an aperient effervescing draught at little expense. Equal weights, a drachm for instance, of the bisulphate and of carbonate of soda, may be dissolved separately, each in two fluidounces of water, then mixed, and taken in the state of effervescence. The dose of the bisulphate is one or two drachms. B.

POTASSÆ TARTRAS. *U. S., Lond., Ed., Dub. Tartrate of Potassa. Soluble Tartar.*

"Take of Carbonate of Potassa *sixteen ounces;* Bitartrate of Potassa [cream of tartar], in fine powder, *three pounds,* or *a sufficient quantity;* Boiling Water *a gallon.* Dissolve the Carbonate of Potassa in the Water; then gradually add the Bitartrate of Potassa to the solution till it is perfectly saturated, and boil. Filter the liquor, evaporate it until a pellicle forms, and set it aside to crystallize. Pour off the liquid, and, having dried the crystals on bibulous paper, keep them in closely stopped bottles." *U. S.*

In the *London Pharmacopœia* of 1851 this salt has been transferred from the Preparations to the catalogue of the Materia Medica.

"Take of Bitartrate of Potash *three pounds;* Carbonate of Potash *sixteen ounces,* or *a sufficiency;* boiling Water *six pints.* Dissolve the Carbonate in the Water, add the Bitartrate till the liquor is neutralized, boil and filter. Concentrate the liquor till a pellicle forms on its surface, and then set it aside to cool and crystallize. The residual liquor will yield more crystals by farther concentration and cooling." *Ed.*

"Take of Carbonate of Potash from Pearlash *eight ounces* [avoirdupois]; white Bitartrate of Potash, in fine powder, *one pound* [avoird.], or *a sufficient quantity;* Distilled Water *half a gallon* [Imp. meas.]. Dissolve the Carbonate of Potash in the Water, and to the solution, while boiling hot, gradually add the Bitartrate, until the liquid, after the ebullition has been continued for a couple of minutes, ceases to change the colour of blue or reddened litmus. Filter through calico,

and, having evaporated the clear liquor until a pellicle forms on its surface, set it by to crystallize. After twelve hours pour off the liquid, and, having dried the crystals on bibulous paper, preserve them in a well stopped bottle." *Dub.*

In these processes, the excess of acid in the bitartrate is saturated by the potassa of the carbonate, the carbonic acid is extricated with effervescence, and the neutral tartrate of potassa is formed. On account of the greater solubility of the carbonate than of the bitartrate, the former is first dissolved, and the latter added to the solution to full saturation. As the bitartrate is gradually added, the mutual action of the salts should be promoted by constant stirring; and the addition should be continued so long as effervescence takes place, which is a better mode of proceeding than to add any specified quantity of the bisalt; since, from its variable quality, it is impossible to adjust precisely the proportions applicable to all cases. It is necessary that the solution should be exactly neutral, or a little alkaline; and hence, if inadvertently too much bitartrate has been added, the proper state may be restored by adding a little of the alkaline carbonate. When the saturation has been completed, the solution is filtered in order to separate tartrate of lime, which appears in white flocks, and which is always present in cream of tartar as an impurity. The evaporated liquor should then be placed in *warm* earthenware vessels, to ensure a slow refrigeration; and, after remaining at rest for several days, the crystals begin to form. In order that the crystallization should proceed favourably, it is necessary, according to Baumé, that the solution should be somewhat alkaline. Iron vessels should not be used in any part of the process; as this metal is apt to discolour the salt.

Tartrate of potassa is sometimes made in the process for preparing tartaric acid. When thus obtained, the excess of acid of the bitartrate is neutralized by means of carbonate of lime. This generates an insoluble tartrate of lime, and leaves the neutral tartrate in solution, from which it may be obtained by evaporation and crystallization. (See *Acidum Tartaricum.*)

Properties, &c. Tartrate of potassa, prepared according to the officinal processes, is in white crystals, which are neutral to test paper, slightly deliquescent, and usually in the form of irregular six-sided prisms with dihedral summits. Its taste is saline and bitter. It dissolves in about twice its weight of cold water, and in much less boiling water, and is nearly insoluble in alcohol. Exposed to heat it undergoes fusion, swells up, blackens, and is decomposed; being converted into carbonate of potassa. For medicinal use it should always be crystallized; but, as it ordinarily occurs in the shops, it is in a white granular powder, obtained by evaporating the solution to dryness, while it is constantly stirred. In this state it is said to require four times its weight of water for solution. It is never purposely adulterated; but, if it be obtained by evaporation to dryness, it is liable to contain an excess of carbonate or of bitartrate of potassa, when it will have either an alkaline or acid reaction. It is decomposed by all the strong acids, and by many acidulous salts, which cause the precipitation of minute crystals of bitartrate of potassa, by abstracting one eq. of alkali from two of the salt. Chloride of barium or acetate of lead occasions a white precipitate of tartrate of baryta or lead, distinguishable from the sulphate of those bases by being wholly soluble in dilute nitric acid. Tartrate of potassa is composed of one eq. of tartaric acid 66, and one of potassa $47{\cdot}2=113{\cdot}2$. According to Berzelius, the crystals contain no water of crystallization.

Medical Properties. Tartrate of potassa is a mild cooling purgative, operating, like most of the neutral salts, without much pain, and producing watery stools. It is applicable to febrile diseases, and is occasionally combined with senna, the griping effects of which it has a tendency to obviate. The dose is from a drachm to an ounce, according to the degree of effect desired. B.

POTASSII BROMIDUM. *U. S.* *Bromide of Potassium.*

"Take of Bromine *two ounces;* Iron Filings *an ounce;* Carbonate of Potassa *two ounces and a drachm,* or *a sufficient quantity;* Distilled Water *four pints.* Add first the Iron Filings, and afterwards the Bromine, to a pint and a half of the Distilled Water, stirring the mixture frequently with a spatula for half an hour. Apply a gentle heat, and, when the liquor assumes a greenish colour, add gradually the Carbonate of Potassa, previously dissolved in a pint and a half of the Distilled Water, until it ceases to produce a precipitate. Continue the heat for half an hour, and then filter. Wash the precipitate with the remaining pint of Distilled Water, boiling hot, and filter. Mix the filtered liquors, and evaporate so that crystals may form. Lastly, pour off the liquid, and dry the crystals on bibulous paper." *U. S.*

In the first step of this process, a solution of bromide of iron is formed; and this, by the addition of the solution of carbonate of potassa, is decomposed so as to generate carbonate of the protoxide of iron which precipitates, and bromide of potassium in solution. By straining, the precipitated carbonate is separated, and from the strained liquor crystals of bromide of potassium are obtained by due evaporation.

Properties, &c. Bromide of potassium is a permanent, colourless, anhydrous salt, crystallizing in cubes or quadrangular prisms, and having a pungent, saline taste, similar to that of common salt, but more acrid. It is very soluble in cold water, more so in hot, and but slightly soluble in alcohol. When heated it decrepitates, and, at a red heat, fuses without decomposition. The following characters are given of the salt in the U. S. Pharmacopœia. "Its aqueous solution does not affect the colour of litmus or turmeric, and is not precipitated by chloride of barium. When mixed with starch, and treated with sulphuric acid, it becomes yellow. The salt, when subjected to heat, does not lose weight. Ten grains of it require, for complete precipitation, 14·28 grains of nitrate of silver, and the precipitate formed has a yellowish colour." The object of adding sulphuric acid along with the starch is to set the bromine free. If iodine be set free at the same time, the starch will give rise to a violet or feeble blue colour. To test for iodine in this salt, Lassaigne recommends to add to its solution a few drops of a weak solution of chlorine, and then to introduce a piece of starched white paper. If iodine be present, the starch will become violet, or faintly blue. If the salt decomposes more nitrate of silver than is above stated, its saturating power is greater than it should be, and the presence of a chloride, probably of potassium or sodium, may be suspected. Bromide of potassium consists of one eq. of bromine 78·4, and one of potassium 39·2=117·6.

Medical Properties. Bromide of potassium is deemed alterative and resolvent. In 1828, Pourché used it with benefit, both internally and in the form of ointment, in the treatment of bronchocele and scrofula. Favourable results were obtained by Dr. Williams, of London, from its use as an internal remedy in several cases of enlarged spleen. According to Ricord, it produces effects in secondary syphilis similar to those of iodide of potassium, but acts more slowly. (See *Potassii Iodidum.*) The same view is taken of its slow action in syphilis by Dr. John Egan. This surgeon, after experimenting with the bromide of potassium for a period of four years in the Westmoreland Lock Hospital, found its effects, in secondary and tertiary syphilis, slow and unsatisfactory, when compared with those of iodide of potassium. While the iodide generally increased the appetite and improved the powers of digestion, the bromide not unfrequently produced nausea and derangement of the digestive organs. (*Am. Journ. of Med. Sci.*, xiv. 206, from the *Dublin Med. Press.*) M. Huette, from extensive trials made with this remedy in the same stages of syphilis, found it inefficacious; exhibiting, in its effects, a marked contrast to those of iodide of potassium, which rapidly

relieved the cases in which the bromide had failed. (*Ann. de Thérap.*, 1851, p. 216.) When given in large doses (from two to five drachms daily), it produces headache, followed by a peculiar intoxication, attended with torpor and drowsiness, slowness of the pulse, temporary dulness of sight and hearing, and weakness of the intellectual faculties. In one case, observed by M. Rames, the insensibility was so complete that the puncture of the skin with a suture needle was not felt, and the titillation of the conjunctiva and fauces with a feather produced neither winking nor desire to vomit. (*Journ. de Pharm.*, Dec. 1849.) Anæsthesia of the fauces, produced by this bromide, was subsequently observed by M. Huette, who also noticed in it the power of inducing more or less torpidity of the genital organs.

Bromide of potassium may be given in the form of pill, or dissolved in water, in doses of from three to ten grains three times a day. The *ointment* may be made by mixing from a scruple to two drachms of the bromide with an ounce of lard. Of this from half a drachm to a drachm may be rubbed on a scrofulous tumour, or other part where its local action is desired, once in twenty-four hours. Sometimes bromine is added to this ointment in the proportion of thirty minims to the ounce of lard. B.

POTASSII CYANURETUM. *U. S.* *Cyanuret of Potassium.*

"Take of Ferrocyanuret of Potassium, dried, *eight ounces;* Carbonate of Potassa, dried, *three ounces.* Mix the salts intimately, and throw the mixture into a deep iron crucible previously heated to redness; maintain the temperature till effervescence ceases, and the fused mass concretes, of a pure white colour, upon a warm glass rod dipped into it; then pour out the liquid carefully into a shallow dish to solidify, stopping before the salt becomes contaminated with the precipitated iron. Break up the mass while yet warm, and preserve it in well stopped bottles." *U. S.*

The above process for obtaining this cyanuret is that of Liebig, modified by C. Clemm, and has been substituted, in the U. S. Pharmacopœia of 1850, for that in which the ferrocyanuret is ignited without addition. It furnishes a large product of cyanuret of potassium, contaminated, but not to an injurious extent, with cyanate of potassa. The reaction takes place between two eqs. of ferrocyanuret of potassium and two of carbonate of potassa. The iron is set free, the carbonic acid evolved, and a compound of five eqs. of cyanuret of potassium and one of cyanate of potassa is formed. The iron occupies the lower part of the fused liquid; and, if the latter be carefully poured out to solidify, the portion contaminated with the iron may be left behind. The reaction is explained by the following equation;—$2(FeCy,2KCy)$ and $2(KO,CO_2)=5KCy+KO,CyO$ and $2Fe$ and $2CO_2$. The cyanate of potassa may be readily detected by saturating the product with an acid, which will cause an effervescence of carbonic acid, and the generation of a salt of ammonia.

In the process in which the ferrocyanuret of potassium is ignited alone (former U. S. process), the salt is first deprived of its water of crystallization by exposure to a moderate heat, and then calcined at a red heat for two hours, in order to decompose the cyanuret of iron. The product of the calcination is a black, porous mass, consisting of cyanuret of potassium, mixed with carburet of iron and charcoal. As the cyanuret is very prone to absorb oxygen, especially when hot, whereby it is decomposed, atmospheric air is excluded from the retort, while it is cooling, by luting its orifice. When the whole is cold, the black mass is reduced to coarse powder, and exhausted by cold distilled water, which dissolves the cyanuret of potassium, and leaves the carburet of iron and charcoal behind. The filtered liquor, therefore, is an aqueous solution of cyanuret of potassium, which is obtained in a solid state by a rapid evaporation to dryness. During the evaporation, a small portion of the cyanuret is decomposed, attended with

the evolution of ammonia, and the production of formiate of potassa. A portion of this salt, therefore, contaminates the cyanuret, as obtained by this process; but the quantity is too small to interfere with its medicinal action. The decomposition here referred to takes place between one eq. of cyanuret of potassium and four of water, and is represented by the following equation, in which the cyanogen is expressed by its full symbol NC_2, and formic acid by C_2HO_3;—K,NC_2 and $4HO=NH_3$ and KO,C_2HO_3. This decomposition is avoided by exhausting the black mass with boiling alcohol of 60 per cent. (sp. gr. 0·896) instead of water. The alcoholic solution, by evaporation to a pellicle, lets fall the salt upon cooling, as a crystalline precipitate, perfectly white and pure.

According to the process of the French Codex, this cyanuret is obtained in the dry way, without the use of any solvent. The calcination is performed in a coated stoneware retort, half-filled with the ferrocyanuret, to which a tube is attached for collecting the gaseous products. When these cease to be disengaged, the heat is gradually raised to a very high temperature, at which it is kept for a quarter of an hour; after which the tube is closed with luting, and the whole left undisturbed until quite cold. When the calcination is thus conducted, the retort, upon being broken, will be found to contain a black matter, covered with a fused layer of pure cyanuret of potassium, resembling white enamel. This is detached by means of a knife, and immediately transferred to a bottle, with an accurately fitting stopper. The black matter, under the name of *black cyanuret of potassium*, is also kept for medicinal use; but the dose of this cannot be accurately fixed, on account of its containing, at different times, more or less impurity.

The French Codex process is commended by Mr. Donovan, of Dublin, as being the best for obtaining this salt. He has modified it by substituting for the stoneware retort, an iron mercury bottle, which, when cold, must be cut in two by a chisel and heavy hammer to get out the product. The details of his mode of proceeding are given by him in the *Pharm. Journ. and Trans.*, ii. 578.

Cyanuret of potassium may be formed by passing a current of nitrogen, previously strongly ignited, over charcoal, impregnated with carbonate of potassa, and heated to whiteness. (See *page* 593.) The same result is obtained, under similar circumstances, by a current of atmospheric air, mixed with watery vapour, according to the plan of M. Armengaud. (*Pharm. Journ. and Trans.*, Dec. 1853, p. 291.)

Properties. Cyanuret of potassium, as prepared by the U. S. formula, is in white, opaque, amorphous masses, having a sharp, somewhat alkaline and bitter-almond taste, and an alkaline reaction. If yellow it contains iron. It is deliquescent in moist air, very soluble in water when reduced to powder, and sparingly soluble in strong alcohol. The salt and its solution, when exposed to the air, exhale the odour of hydrocyanic acid, and become weaker; but the change takes place slowly. Orfila found that the salt, after fourteen days' exposure, by which it was almost entirely liquefied, still possessed energetic poisonous properties. He thinks, therefore, that the bad effects of opening the containing bottle, in dispensing the medicine, have been exaggerated. Unfortunately, the salt varies in quality, independently of the effects of time and exposure. Dr. David Stewart, of Baltimore, examined six samples of this cyanuret, on sale, and found them to vary considerably in purity. Besides water, the usual impurities are hydrate, carbonate, cyanate, and formiate of potassa. These sometimes amount to nearly half the weight of the cyanuret, consisting principally of the carbonate. From the extensive use at present made of cyanuret of potassium in electro-metallurgy and photography, it is of importance to have a reliable test of its purity. Such a test has been discovered by MM. Fordos and Gélis, founded on the fact that two eqs. of iodine rapidly react with one of the cyanuret, so as to form one eq.

of iodide of potassium, and one of iodide of cyanogen;—KCy and 2I=KI and CyI. Accordingly, a tincture of iodine of known strength is gradually added to an aqueous solution of a given weight of the cyanuret to be tested, until it assumes a permanent yellowish tinge; and the amount of iodine expended indicates the proportion of cyanuret in the specimen. A necessary preliminary step, before using the tincture, is to add sufficient carbonic acid water to the solution of the cyanuret, to convert any hydrate or carbonate of potassa present into bicarbonates, in which state these impurities have no action on the iodine. (*Chem. Gaz.*, Oct. 15, 1852, p. 387.) This test is applicable to other cyanogen compounds. (See *page* 809.) Cyanuret of potassium yields with nitrate of silver a precipitate of cyanuret of silver, which is wholly soluble in ammonia. It consists of one eq. of cyanogen 26, and one of potassium 39·2=65·2.

Medical Properties. Cyanuret of potassium is pre-eminently poisonous, acting precisely like hydrocyanic acid as a poison and as a medicine. (See *Acidum Hydrocyanicum.*) The grounds on which it was proposed as a substitute for that acid by Robiquet and Villermé, are its uniformity as a chemical product, and its less liability to undergo decomposition. The dose is the eighth of a grain, dissolved in half a fluidounce of distilled water, to which may be added half a fluidrachm of syrup of lemons, if the prescriber wishes to set free hydrocyanic acid. (*Donovan.*) The spurious cyanuret, formed by calcining dried muscular flesh with potash, consists principally of carbonate of potassa, and is but slightly poisonous. (*Orfila.*) A solution, made with from one to four grains to the fluidounce of water, has been recommended in neuralgic and other local pains, applied by means of pieces of linen. Mr. Guthrie found that a solution of from three to six grains to the fluidounce of distilled water, formed an admirable remedy, applied by drops every other day, for removing the olive-coloured stains of the conjunctiva, caused by nitrate of silver. B.

POTASSII IODIDUM. *U. S.*, *Lond.*, *Ed.*, *Dub.* *Iodide of Potassium.*

"Take of Potassa *six ounces;* Iodine, in powder, *sixteen ounces;* Charcoal, in fine powder, *two ounces;* Boiling Water *three pints.* Dissolve the Potassa in the Water, add the Iodine gradually, stirring after each addition until the solution becomes colourless, and continue the additions until the liquid remains slightly coloured from excess of Iodine. Evaporate the solution to dryness, stirring in the Charcoal towards the close, so that it may be intimately mixed with the dried salt. Rub this to powder, and heat it to dull redness in an iron crucible, maintaining that temperature for fifteen minutes; then, after it has cooled, dissolve out the saline matter with pure water, filter the solution, evaporate, and set aside to crystallize. An additional quantity of crystals may be obtained from the residual liquid by evaporating and crystallizing as before." *U. S.*

In the *London Pharmacopœia* of 1851, iodide of potassium has been transferred from the preparations to the list of Materia Medica.

"Take of Iodine (dry) *five ounces;* fine Iron Wire *three ounces;* Water *four pints* [Imp. meas.]; Carbonate of Potash (dry) *two ounces and six drachms.* With the Water, Iodine, and Iron Wire prepare the solution of iodide of iron as directed [under Ferri Iodidi Syrupus]. Add immediately, while it is hot, the Carbonate of Potash previously dissolved in a few ounces of water, stir carefully, filter the product, and wash the powder on the filter with a little water. Concentrate the liquor at a temperature short of ebullition, till a dry salt be obtained, which is to be purified from a little red oxide of iron and other impurities, by dissolving it in less than its own weight of boiling water, or still better by boiling it in twice its weight of rectified spirit, filtering the solution, and setting it aside to crystallize. More crystals will be obtained by concentrating and cooling the residual liquor." *Ed.*

"Take of Pure Iodine, reduced to powder, *four ounces and a half* [avoirdupois]; filings, or thin turnings of wrought Iron, separated from impurities by a magnet, *two ounces* [avoird.]; Pure Carbonate of Potash *two ounces and a half* [avoird.], or *a sufficient quantity;* Distilled Water *three pints and a half* [Imp. meas.]. Heat gently five ounces of the Water with the Iron and three ounces of the Iodine, for twenty minutes, and then boil until the solution loses its red colour. Filter this through paper, washing the filter with five ounces of Water at a boiling temperature, and, in the solution thus obtained, dissolve, by digestion and shaking, the remainder of the Iodine. To the Carbonate of Potash, dissolved in a quart [two pints Imp. meas.] of the Water, and heated to 212° in a large porcelain capsule, add the solution of Iron and Iodine, and boil until effervescence ceases, adding, if necessary, a little more Carbonate of Potash, so that the liquor may be very slightly alkaline. Filter now, washing the precipitate with the remaining pint of water boiling hot, and, having evaporated the liquid till a pellicle begins to appear on its surface, let it be set by that crystals may form These, when dried on blotting paper, should be preserved in a bottle furnished with a perfectly tight stopper. The liquor from which the crystals have separated will, by further evaporation and cooling, afford an additional quantity of the salt." *Dub.*

In the process newly adopted in the U. S. Pharmacopœia of 1850, an aqueous solution of potassa is treated with iodine in slight excess. The result of thus saturating potassa with iodine is the formation of two salts, iodide of potassium and iodate of potassa. Six eqs. of iodine react with six of potassa, and there are formed five eqs. of iodide of potassium, and one of iodate of potassa;—6I and 6KO=5KI and KO,IO_5. By evaporating the solution to dryness the mixed salts are obtained; and, if the dry mass be exposed to a red heat, the iodate will be converted into iodide of potassium, thus removing this impurity from the iodide. In the formula the mixed salts, towards the close of their evaporation to dryness, are directed to be mixed with powdered charcoal, according to the plan of Mr. Scanlan, which facilitates the deoxidation of the iodate. This being accomplished by a dull red heat, the iodide of potassium is dissolved out of the mass, and the solution set aside to crystallize.

The first step of the Edinburgh process is to form the iodide of iron in solution, precisely as is done in the formula for that compound; and the second to decompose it by carbonate of potassa, which gives rise to iodide of potassium in solution, and a precipitate of carbonate of protoxide of iron. The solution of iodide of potassium is separated by filtration and washing from the precipitated carbonate, and evaporated to dryness. The dry salt is then freed from iron and other impurities by solution in boiling water or alcohol, filtration and crystallization. Messrs. T. and H. Smith, of Edinburgh, instead of washing the precipitate, prefer the plan of pressing it strongly in a cloth, in order to extract the remains of the solution. The mass left is broken up in a portion of distilled water equal to about two-thirds of the weight of the iodine employed, and pressed a second time. Proceeding thus, less water is used, and less evaporation is necessary. The solution obtained by them is evaporated to dryness, and the dry salt is carefully fused in an iron pot, in order to free it from colour. It is then dissolved, and the solution, by filtration, concentration, and cooling, furnishes a perfectly pure iodide nearly to the last.

The Dublin process is similar to that of the Edinburgh College. Two-thirds of the iodine are gently heated with the iron mixed with a portion of water, and the filtered solution of the iodide of iron formed is shaken with the remaining third of the iodine until it is dissolved. There is thus formed what may be called a superiodide of iron, which is mixed in the usual way with the carbonate of potassa, and the mixture boiled until effervescence ceases. By this boiling

the salts are made fully to react on each other, and the filtered solution prevented from being contaminated with iron. The Dublin College very properly orders the use of the pure carbonate of potassa in this process, in accordance with the practice of the Messrs. Smith.

Properties, &c. Iodide of potassium, sometimes incorrectly called *hydriodate of potassa*, is in opaque, white or transparent crystals, permanent in a dry air, slightly deliquescent in a moist one, and having a sharp saline taste. It does not change the colour of litmus, and has little or no effect on turmeric. According to the Messrs. Smith, of Edinburgh, it is not at all deliquescent when perfectly pure. It generally crystallizes in cubes. It is soluble in about two-thirds of its weight of cold water, and in from six to eight parts of rectified spirit. Its solution is decomposed by sulphuric acid, which acts by generating hydriodic acid, which speedily undergoes decomposition, with evolution of iodine; and, if starch be added after the lapse of a few minutes, a blue colour is generated. The starch test will not give the characteristic blue colour immediately, if added simultaneously with the acid, unless the iodide of potassium contains iodate of potassa, which impurity causes an immediate liberation of iodine. The blue colour being produced by the starch and acid, simultaneously added, is, therefore, a sign of impurity. A very delicate test of iodide of potassium, and other soluble iodides, is that of M. Grange. It consists in pouring a little of the liquid to be examined into a test-tube, adding a few drops of solution of starch, and passing through the mixture a few bubbles of fuming nitrous acid. The liquid immediately assumes a pale-rose colour, inclining to violet, when containing 1-200,000th of its weight of the iodide, and a bright blue colour, if 1-100,000th is present. See *page* 408. (*Chem. Gaz.*, Jan. 1, 1852, p. 19.) "When tartaric acid is freely added to a strong solution of the iodide, it occasions a white crystalline precipitate; and the supernatant liquid, if mixed with starch, becomes first purple, and finally blue. Chloride of platinum colours its solution reddish-brown, without causing a precipitate; chloride of barium but slightly affects it; and sulphate of iron occasions no change." (*U. S. Pharm.*) The non-action of the last test shows the absence of carbonate of potassa. The aqueous solution is capable of taking up a large quantity of iodine, forming a liquid, containing the iodurettted iodide, of a deep-brown colour. Exposed to a dull red heat it fuses, and on cooling concretes into a crystalline pearly mass, without loss of weight; but at a full red heat it is slowly volatilized without decomposition. The most usual impurities contained in this salt are the chlorides of potassium and sodium, bromide of potassium, and iodate and carbonate of potassa. The presence of a chloride may be determined by the use of nitrate of silver. This test will throw down nothing from the pure salt but iodide of silver, which is scarcely soluble in ammonia; while chloride of silver is readily soluble in it. If then a solution of the iodide be precipitated by an excess of nitrate of silver, and agitated with ammonia, the latter will dissolve any chloride which may have been thrown down, and will yield it again as a white precipitate on being saturated with nitric acid. If, on the other hand, the iodide of potassium be pure, the ammonia will only take up a minute quantity of iodide of silver, and the addition of nitric acid will scarcely disturb the transparency of the solution. The iodide of silver thrown down from 10 grains of iodide of potassium weighs, when washed and dried, 14·1 grains. When acetate of lead is added to a solution of iodide of potassium, a yellow precipitate of iodide of lead is thrown down, soluble in boiling water. The low price of bromide of potassium, compared with that of the iodide, has caused the former to be used to adulterate the latter. When bromide of potassium is sold for the iodide, the fraud may be detected by the fact that the bromide produces no precipitate with bichloride of mercury. In order to detect bromine, M. Personne first precipi-

tates from an aqueous solution of the suspected iodide, the whole of the iodine as protiodide of copper, by successively adding, in excess, a solution of sulphate of copper, and aqueous sulphurous acid; and then treats the filtered liquid with ether and chlorine water, the whole being shaken together and left at rest. If bromine be present, the ether which rises to the surface, will be tinged of a reddish-yellow colour. The iodate and carbonate may be detected by their insolubility in alcohol. The iodate may be detected also by adding a solution of tartaric acid to a solution of the suspected iodide. Bitartrate of potassa will be precipitated, and, if the iodide be pure, a yellow colour is *soon* developed from the action of the air on the liberated hydriodic acid; but, if any iodate be present, the test will set free both iodic and hydriodic acid, which, by their reaction, will *instantly* develope free iodine. (*Pereira.*) Carbonate of potassa is generally present in the proportion of from one to ten per cent. Dr. Christison has detected 74½ per cent. and Dr. Pereira as high as 77 per cent. An adulteration by the carbonate under ten per cent. does not alter the crystalline appearance of the iodide, but gives it an increased tendency to deliquesce. When it is greater it renders the salt granular and highly deliquescent. This impurity may be detected by lime-water, which causes a milkiness (carbonate of lime), and by tincture of iodine, the colour of which is destroyed. Another impurity, found by A. Erdmann, is bicarbonate of soda. It was detected by adding to a small portion of the suspected sample, sufficient water to dissolve it if pure. This left the impurity in fragments of crystals, which required from thirteen to fourteen parts of water to dissolve them. Upon examination they effervesced with acids, and proved to be bicarbonate of soda. (J. M. Maisch, *Am. Journ. of Pharm.*, xxvi. p. 210.) Iodide of potassium consists of one eq. of iodine 126·3, and one of potassium, 39·2=165·5. It contains no water of crystallization.

Professor Procter has given a paper on the incompatibles of iodide of potassium, in relation to the mercurial preparations. He finds it incompatible with calomel, the black and red oxides of mercury, turpeth mineral, white precipitate, blue mass, and metallic mercury. These experiments serve to confirm the results of M. Melsens, that iodide of potassium, given in connexion with the insoluble preparations of mercury, renders them soluble and much more active. (See *Am. Journ. of Pharm.*, xxvi. p. 222.)

Medical Properties and Uses. This salt produces very marked effects on the secretions in general, which it increases, and into which it readily passes. It has a tendency to irritate the mucous membrane of the air-passages, as is shown by its sometimes occasioning an affection like cold in the head. Dr. D. P. Phillips, U. S. Navy, reports a case in which it appeared to produce trismus, which he attributed to the use of the medicine in too concentrated a solution. (*Med. Exam.*, May, 1853.) When long continued in large doses it sometimes produces a tender, enlarged, lobulated, and fissured tongue, constituting a true chronic glossitis. Mr. Langston Parker, of England, has reported several cases of this kind, in which the iodide had been taken for years. (See *Am. Journ. of Med. Sci.*, Oct. 1852, p. 495.) Its obvious effects on the system are very variable, arising probably either from peculiarities of constitution, or from the unequal quality of the medicine itself. Thus, in some cases it produces nausea, pain in the stomach, and diarrhœa, in moderate doses; and in others is borne in large doses without inconvenience. Sometimes it increases the appetite and the flesh. By some practitioners it is preferred for the purpose of producing the constitutional effects of iodine. Dr. De Renzy, of Carnew, used it with great success in hæmoptysis, and Dr. Graves, of Dublin, employed it with advantage in a very obstinate erythematic swelling of the hand. M. Oke praises its effects in chorea, after the preparations of iron have failed. Dr. Williams, of London, considers it applicable to the treatment of various forms of secondary syphilis. He used

it with success, in a majority of cases, in removing hard periosteal nodes, and found it beneficial in the treatment of tubercular forms of venereal eruptions. It is also considered as one of the best alterative remedies in mercurio-syphilitic sorethroat. Ricord bears testimony to its valuable powers in the treatment of secondary syphilis. According to the clinical observations of Dr. W. R. Basham, of London, iodide of potassium is well suited to the treatment of chronic periosteal rheumatism in subjects who have previously taken mercury to salivation; while it is not applicable to the disease when occurring in patients who have not undergone a mercurial course, but have suffered from syphilis, which has been neglected, or treated only locally. In the latter cases he conceives that corrosive sublimate and sarsaparilla are the proper remedies. (See *Am. Journ. of Med. Sci.*, Jan. 1854, p. 227.) It is probably useful in the former cases on the principle of eliminating mercury from the system, agreeably to the views of M. Melsens, given below. In 1843, MM. Guillot and Melsens gave iodide of potassium with advantage, in doses of from a drachm to a drachm and a half daily, in mercurial tremours and lead poison. In a memoir published in 1849, M. Melsens gives a full account of his experiments with it as a remedy for the affections caused by mercury and lead. He effected a number of cures of mercury tremours and lead palsy; and during the progress of the cure, these metals were found in the urine. The manner in which the remedy acts, according to M. Melsens, is by rendering the poisonous metal, which has become fixed in the tissues, soluble, first converting it into an iodide, and then dissolving the iodide formed. This view is supported by the fact that all the compounds of mercury and lead are soluble in iodide of potassium. (See the Memoir of M. Melsens, translated by Dr. Budd, of Bristol, England, in the *Brit. and For. Medico-Chir. Review*, Am. ed., for Jan. 1853, p. 157; also a paper by Dr. J. W. Corson, in the *N. Y. Journ. of Medicine*, for Sept. 1853.) An important fact observed by M. Melsens was that iodide of potassium, given at the same time with certain compounds of mercury, rendered them more active; and, when given after the latter, developed an activity not previously manifested, and sometimes to such an extent as to occasion serious accidents. This fact he attributed to the power of the iodide to render the mercurial compounds soluble, in which state only are they capable of being eliminated with the urine. During the use of iodide of potassium, ptyalism sometimes occurs. This has been usually considered a primary effect of the remedy; but the light shed on the subject by M. Melsens, leads to the belief that it may be a secondary effect, resulting from the liberation from the tissues of mercury previously taken, which is thereby enabled, by becoming soluble, to produce its constitutional effects. Dr. Budd relates several cases, in which mercurial ptyalism came on, during the use of iodide of potassium, in persons who had not taken mercury for weeks or months before. These facts render it probable that the different cases of ptyalism, reported as the result of iodide of potassium, were in fact produced by mercury, previously fixed in the system, being rendered soluble and active by the iodide.

The late Dr. Isaac Parrish, of this city, employed iodide of potassium successfully in strumous inflammation of the eye, given in the compound syrup of sarsaparilla. It appeared promptly to relieve the severe neuralgic, circumorbital pain. Dr. G. L. Upshur, of Virginia, recommends its use in the suppurative stage of pneumonia. The dose is from two to ten grains or more, three times a day, given in solution. Ricord rarely exceeded three scruples a day. Some practitioners have reported the exhibition of enormous doses, such as two, four, and even six drachms daily without inconvenience. Dr. Buchanan, of Glasgow, assures us that he has given the pure salt in doses of half an ounce, without any precaution being observed by the patient, except to drink freely of diluents. Notwithstanding this testimony, Dr. Lawrie, of the same city, reports several

cases of dryness and irritation of the throat, ending in severe spasmodic croup, and one case of death following the sudden occurrence of dyspnœa, caused by the use of small doses of this iodide.

Prof. Brainard, of Chicago, has proposed as a remedy for the bite of the rattlesnake, the infiltration of the tissues, where the bite has been inflicted, with from half a drachm to a drachm and a half of a solution of fifteen grains of iodide of potassium and five of iodine in a fluidounce of distilled water. A cupping glass is applied over the wound as soon as possible, and the infiltration effected by passing beneath the skin, under the edge of the cup, a small trocar, through the cannula of which the solution is injected. Forty experiments were tried with this treatment on pigeons, kittens, and dogs, with generally successful results. Prof. Brainard proposes to extend it to dissection wounds, and all poisoned wounds of a dangerous character. (*N. Y. Med. Times*, iii. 210.)

Iodide of potassium passes quickly into the urine, in which it may be detected by first adding to the cold secretion a portion of starch, and then a few drops of nitric acid, when a blue colour will be produced. It has been detected in six minutes after having been swallowed.

According to Ricord, this salt produces in some constitutions peculiar effects, such as various eruptions of the skin, excessive diuresis, vascular injection of the conjunctiva and tumefaction of the eyelids, cerebral excitement like that produced by alcoholic drinks, and discharges from the urethra and vagina, resembling blennorrhœa. Eruptions of the skin were also observed by Dr. A. Van Buren, as a very common effect of large and long continued doses of iodide of potassium, given to patients in the Bellevue Hospital. (*N. Y. Journ. of Med.*, viii. 208.) Dr. John O'Rielly, of New York, reports several cases, in which, after the use of this iodide, spots like purpura were produced, invading first the face, and then the trunk and extremities. These became bullæ, sometimes an inch in diameter, filled with a purple liquid, and finally sphacelated spots ending in ulcers. Great constitutional disturbance coexisted, with swollen tongue, fetor, and salivation. The remedies found successful were nutritious diet, tonics, and stimulants. (*N. Y. Med. Gaz.*, v. 7.) From the facts mentioned above, showing the power of iodide of potassium to render latent mercury in the system active, it is not improbable that the cases of Dr. O'Rielly were mercurial salivation, modified by a cachectic condition of the system, which caused the coincident eruption.

Iodide of potassium is employed as an external application in the form of ointment, either alone or mixed with iodine. (See *Unguentum Potassii Iodidi* and *Unguentum Iodinii Compositum.*)

Off. Prep. Emplastrum Potassii Iodidi; Hydrargyri Iodidum Rubrum; Liquor Iodinii Compositus; Liquor Potassii Iodidi Compositus; Pilulæ Ferri Iodidi; Plumbi Iodidum; Tinctura Iodinii Composita; Unguentum Iodinii; Unguentum Iodinii Compositum; Unguentum Potassii Iodidi. B.

LIQUOR POTASSII IODIDI COMPOSITUS. *Lond.* Potassii Iodidi Liquor Compositus. *Dub.* *Compound Solution of Iodide of Potassium.*

"Take of Iodide of Potassium *ten grains;* Iodine *five grains;* Distilled Water *a pint* [Imp. meas.]. Mix, that they may dissolve." *Lond.*

The *Dublin* formula is the same as the above, with the exception that the College directs its pure iodine.

This, like the compound solution of iodine, described at *page* 1064, is an aqueous solution of iodine and iodide of potassium; but, while the compound solution of iodine is so concentrated as to be given in drops, the compound solution of iodide of potassium is so dilute as to be administered in tablespoonfuls.

Compound solution of iodide of potassium is twice as strong as Lugol's iodu-

retted mineral water of *medium* strength, assuming the Imperial fluidounce to be the same as the French ounce. (See *page* 411.) The dose is a fluidounce, containing a quarter of a grain of iodine, gradually increased to two fluidounces or more. The dose should be diluted with an equal bulk of water at the time it is taken. B.

POTASSII SULPHURETUM. *U. S., Lond., Ed.* HEPAR SULPHURIS. *Dub. Sulphuret of Potassium. Liver of Sulphur.*

"Take of Sulphur *an ounce;* Carbonate of Potassa *two ounces.* Rub the Carbonate of Potassa, previously dried, with the Sulphur; melt the mixture in a covered crucible over the fire; then pour it out, and, when it is cold, put it into a bottle, which is to be well stopped." *U. S.*

"Take of Sulphur *one ounce;* Carbonate of Potash *four ounces.* Triturate them well together, and heat them in a covered crucible till they form a uniform fused mass; which, when cold, is to be broken up into fragments, and kept in well closed vessels." *Ed.*

"Take of Sublimed Sulphur *four ounces;* Carbonate of Potash from Pearlash, first dried, and then reduced to powder, *seven ounces.* Mix the ingredients in a warm mortar, and, having introduced them into a Hessian crucible, let this be heated, first gradually, until effervescence has ceased, and finally to low redness, so as to produce perfect fusion; and let its liquid contents be then poured into an iron cup, over which a second vessel should be immediately inverted, so as to exclude the air as completely as possible, while solidification is taking place. The solid product thus obtained should, when cold, be broken into fragments, and immediately enclosed in a green glass bottle, furnished with an air-tight stopper." *Dub.*

The *London College* has transferred this sulphuret to its Materia Medica list.

When carbonate of potassa is melted with half its weight of sulphur, as in the U. S. process, the carbonic acid is expelled. Four eqs. of potassa and ten of sulphur may be supposed to react on each other. Three eqs. of potassa are decomposed into three eqs. of potassium and three of oxygen. The three eqs. of potassium unite with nine eqs. of sulphur to form three eqs. of tersulphuret of potassium. The three eqs. of oxygen, by uniting with the remaining eq. of sulphur, form sulphuric acid, which combines with the undecomposed eq. of potassa to form sulphate of potassa. Thus the U. S. preparation may be considered to be a mixture of tersulphuret of potassium with sulphate of potassa; and the French Codex sulphuret, made from the same proportion of carbonate and sulphur, is stated in that work to have the same composition. In the Dublin formula a less proportion of carbonate of potassa is taken than in the U. S. process, but the product is probably very similar. The product of the Edinburgh formula may be assumed to have the same constituents, *plus* a certain proportion of undecomposed carbonate of potassa, on account of the large excess of alkali taken. In performing the process, the fused liquid is usually poured out on a marble slab, and, as soon as it concretes, the mass should be broken into pieces, and immediately transferred to a well-stopped bottle.

The Pharmacopœias use the carbonate of potassa from pearlash; but in the process of M. Henry, which is stated to be the best yet devised, the pure carbonate of potassa is employed. His formula is as follows. Mix two parts of real salt of tartar with one of roll sulphur reduced to powder, and put the mixture into flat-bottomed matrasses, which should be only two-thirds filled. These are placed on a sand-bath, and the fire is applied, so as, at first, to produce only a gentle heat, which is afterwards increased. Care must be taken that the necks of the matrasses do not become obstructed. The heat is continued until the matter is brought to the state of tranquil fusion, when it is allowed to cool. The

mass obtained, which is compact, smooth, and of a fine yellow colour, is broken into pieces, and preserved in well-stopped bottles.

Properties, &c. Sulphuret of potassium, when properly prepared, is a hard brittle substance, having a nauseous, alkaline, and bitter taste. Its colour is liver-brown, and hence its name of *hepar sulphuris* or *liver of sulphur*. The colour of the surface of a fresh fracture is brownish-yellow. It is inodorous when dry, but emits a slightly fetid smell when moist, owing to the extrication of a little sulphuretted hydrogen gas. It is completely soluble in water, forming an orange-yellow liquid, and exhaling the smell of sulphuretted hydrogen. By exposure to the air it attracts oxygen, and the sulphuret of potassium is gradually converted into sulphate of potassa, when the preparation becomes inodorous, and white on the surface. The solution is decomposed by the mineral acids, which extricate sulphuretted hydrogen, and precipitate the excess of sulphur. It is also incompatible with solutions of most of the metals, which are precipitated as sulphurets. When boiled with an excess of muriatic acid and filtered, it gives a yellow precipitate with chloride of platinum. B.

Medical Properties and Uses. Sulphuret of potassium is a local irritant, and, in small and repeated doses, is said to increase the frequency of the pulse, the heat of the skin, and the different secretions, especially the mucous. Occasionally it vomits and purges. It acts, moreover, as an antacid, and produces the alterative effects of sulphur. By some it is maintained to be sedative, and directly to reduce the action of the heart. It probably does so, when taken in considerable quantities, by the development of sulphuretted hydrogen. In overdoses it acts, according to Orfila, as a violent poison, corroding the stomach, and depressing the powers of the nervous system. Acetate of lead, or acetate of zinc may be used as an antidote; but the latter is preferable, as less likely to act injuriously in an overdose, and having besides emetic properties. The complaints in which it has been most advantageously employed are chronic rheumatism and gout, and various cutaneous affections. It has been given also in painters' colic, asthma, and chronic catarrh, and acquired a short-lived reputation as a remedy in croup, after the publication of the essay to which the prize offered by Napoleon for the best dissertation on that disease was awarded. It is said, in some cases of cancer, to have assisted the palliative operation of hemlock. In consequence of forming insoluble sulphurets with the metallic salts, it has been proposed as an antidote for some of the mineral poisons; but Orfila has proved that it does not prevent their effects. Dissolved in water it has proved very efficacious as an external application in cutaneous diseases, and in scabies is an almost certain remedy. It may be used for this purpose in the form of lotion, bath, or ointment. For a lotion it may be dissolved in water in the proportion of from fifteen to thirty grains to the fluidounce, and for a bath, the same quantity or rather more may be added to a gallon of water. A very small proportion of muriatic or sulphuric acid may in either case be added to the solution. The ointment is made by mixing half a drachm of the sulphuret with an ounce of lard. The dose of sulphuret of potassium is from two to ten grains, repeated several times a day, and given in pill with liquorice, or in solution with syrup. In infantile cases of croup, from one to four grains were given every three or four hours. W.

PULPÆ.

Pulps.

These are soft uniform solid bodies, of a consistence fit for the formation of confections or electuaries, and prepared from fruits by comminuting them when

requisite, softening them when dry with a small quantity of hot water, then passing them through a sieve to separate hard solid matters, and evaporating if necessary. But few of them are officinal. W.

CASSIÆ FISTULÆ PULPA. *U.S.* Cassia Præparata. *Lond.* Cassiæ Pulpa. *Ed.* *Pulp of Purging Cassia.*

"Take of Purging Cassia, bruised, a *convenient quantity*. Pour boiling water on the pods so that the pulp may be softened; then strain, first through a coarse sieve, and afterwards through a hair one, and evaporate by means of a water-bath to the proper consistence." *U. S.*

"Take of Cassia [pods of Cassia Fistula] broken longitudinally *a pound;* Distilled Water sufficient to cover the Cassia. Macerate for six hours, occasionally stirring. Strain the softened pulp through a hair sieve, and evaporate by means of a water bath to the consistence of a confection." *Lond.*

The *Edinburgh College* places cassia pulp in its catalogue of Materia Medica.

In consequence of the presence of the fragments of the pods, it is inconvenient to pass this pulp in the ordinary way through a hair sieve. The larger fragments may be picked out, and the remainder of the cassia pressed by the hand through a very coarse kind of muslin, such as that used by the bonnet-makers, in which it has been previously enclosed. A pound of the pods will yield between four and five ounces of pulp.

Cassia pulp has a blackish colour, a slight rather sickly odour, and a sweet mucilaginous taste. It is apt to become sour by exposure. For its composition and effects, see *Cassia Fistula.*

Off. Prep. Confectio Cassiæ; Confectio Sennæ. W.

PRUNI PULPA. *U.S.* Prunum Præparatum. *Lond.* *Pulp of Prunes.*

"Take of Prunes *a convenient quantity*. Soften the Prunes in the vapour of boiling water, and, having separated the stones, beat the remainder in a marble mortar, and press it through a hair sieve." *U. S.*

"Take of Prunes *a pound;* Water sufficient to cover the Prunes. Boil slowly for four hours. Express the softened pulp, first through a coarse cane sieve, afterwards through a fine one of hair. Lastly, evaporate by means of a water-bath to the consistence of a confection." *Lond.*

The prunes may be softened by placing them on a perforated plate or diaphragm, or a wire sieve, or suspending them in a net, over boiling water. A pound of prunes of good quality yields about ten ounces of pulp.

Off. Prep. Confectio Sennæ. W.

TAMARINDI PULPA. *U.S.* Tamarindus Præparatus. *Lond.* Tamarindus. *Ed.* Pulp of Tamarinds. *Dub.* *Pulp of Tamarinds.*

"Take of Tamarinds *a convenient quantity*. Digest them with a small quantity of water until they become of a uniform consistence; then separate the seeds and filaments by pressing the pulp through a hair sieve." *U. S.*

"Take of Tamarinds *a pound;* Water sufficient to cover the Tamarinds. Macerate with a gentle heat for four hours, and complete the process in the manner directed for Prepared Prunes." *Lond.* (See *Pruni Pulpa.*)

The *Edinburgh* and *Dublin Colleges* place this pulp in their catalogue of Materia Medica.

The tamarinds should be digested in an unglazed earthenware vessel over hot ashes, or by means of a sand-bath. The operator should be specially cautious not to employ iron vessels or iron spatulas in making this preparation. A pound of good tamarinds will yield a little more than seven ounces of pulp.

Off. Prep. Confectio Cassiæ; Confectio Sennæ. W.

PULVERES.

Powders.

The form of powder is convenient for the exhibition of substances which are not given in very large doses, are not very disagreeable to the taste, have no corrosive property, and do not deliquesce rapidly on exposure. As the effect of pulverization is to expose a more extended surface to the action of the air, care should be taken to keep substances which are liable to be injured by such exposure in closely stopped bottles. In many instances it is also important to exclude the light, which exercises a deleterious influence over numerous medicines when minutely divided. This may be done by coating the bottles with black varnish. In relation to substances most liable to injury from these causes, the best plan is to powder them in small quantities as wanted for use.

Powders may be divided into the *simple*, consisting of a single substance, and the *compound*, of two or more mixed together. The latter only are embraced under the present head. In the preparation of the compound powders, the ingredients, if of different degrees of cohesion or solidity, should be pulverized separately and then mixed. An exception, however, to this rule is the employment of one substance to facilitate by its hardness the minute division of another, as in the *powder of ipecacuanha and opium*. Deliquescent substances, and those containing fixed oil in large proportion, should not enter into the composition of powders intended to be kept; the former, because they render the preparation damp and liable to spoil; the latter, because they are apt to become rancid, and impart an unpleasant odour and taste. When deliquescent substances are extemporaneously prescribed, the apothecary should enclose them before delivery in tin foil or other impervious covering; and the same remark is applicable to volatile powders, as carbonate of ammonia and camphor.

The lighter powders may in general be administered in water or other thin liquid; the heavier, such as those of metallic substances, require a more consistent vehicle, as syrup, molasses, honey, or one of the confections. Resinous powders, if given in water, require the intervention of mucilage or sugar.

The *London College* gives the following general directions for the preparation of powders. "It is necessary that whatever we direct to be reduced to powder should be so passed through a fine sieve that the impurities and thicker parts may be separated. It is proper that most powders should be recently prepared, and not kept long." The whole substance in the mortar should not be beaten till completely pulverized; as the portion already powdered interferes with the action of the pestle upon the remainder, while the finer matter is apt to be dissipated; so that there is a loss both of time and material. The proper plan is to sift off the fine powder after a short trituration, then to return the coarser parts to the mortar, and to repeat several times this alternate pulverization and sifting, until the process is completed. W.

PULVIS ALOËS COMPOSITUS. *Lond.* *Compound Powder of Aloes.*

"Take of Socotrine or Hepatic Aloes *an ounce and a half;* Guaiacum [Resin] *an ounce;* Compound Powder of Cinnamon *half an ounce.* Rub the Aloes and Guaiacum, separately, into powder; then mix them with the Compound Powder of Cinnamon." *Lond.*

The tendency of pulverized guaiac to concrete, and the excessively bitter taste of aloes, which is but imperfectly concealed by the aromatic addition, render the form of powder ineligible for the exhibition of these medicines. The preparation

is a warm stimulant cathartic, but is little used. The dose is from fifteen to thirty grains. W.

PULVIS ALOËS ET CANELLÆ. *U.S.* *Powder of Aloes and Canella. Hiera Picra.*

"Take of Aloes *a pound;* Canella *three ounces.* Rub them separately into a very fine powder, and mix them." *U. S.*

This preparation has long been known under the name of *hiera picra.* The canella serves to correct the griping property, and imperfectly to cover the taste of the aloes; but the bitterness of the latter is still very obvious in the mixture, which would be better given in the form of pill. It is a popular remedy in amenorrhœa, and may be used for all the purposes to which aloes is applied. It is sometimes administered in domestic practice, infused in wine or spirit. The dose is from ten to twenty grains. W.

PULVIS ALUMINIS COMPOSITUS. *Ed.* *Compound Powder of Alum.*

"Take of Alum *four ounces;* Kino *one ounce.* Mix them, and reduce them to fine powder." *Ed.*

A solution of alum is decomposed by a solution of kino, and it is probable that the same effect takes place when the two substances, mixed in the state of powder, are introduced into the stomach; but whether their astringency is materially affected by the change is uncertain. The preparation may be employed in diarrhœa, menorrhagia, and hemorrhage from the stomach or bowels, and externally to suppress hemorrhage, or as an astringent application to flabby ulcers. The dose is from five to twenty grains. W.

PULVIS AROMATICUS. *U.S., Ed., Dub.* PULVIS CINNAMOMI COMPOSITUS. *Lond.* *Aromatic Powder.*

"Take of Cinnamon, Ginger, each, *two ounces;* Cardamom, deprived of the capsules, Nutmeg, grated, each, *an ounce.* Rub them together into a very fine powder." *U. S.*

The *London College* directs *two ounces* of cinnamon, *an ounce and a half* of cardamom, *an ounce* of ginger, and *half an ounce* of long pepper; the *Edinburgh*, *equal parts* of cinnamon, cardamom, and ginger; the *Dublin*, *two ounces*, each, of cinnamon and ginger, and *an ounce*, each, of cardamom seeds freed from their capsules, and of nutmeg.

The cardamom seeds should always be separated from their capsules before pulverization; and the powder, when prepared, should be kept in well stopped bottles. The London preparation is more pungent than the others, in consequence of the long pepper which it contains. These powders are stimulant and carminative, and may be given in the dose of from ten to thirty grains, in cases of enfeebled digestion accompanied with flatulence; but they are chiefly used as corrigents and adjuvants of other medicines. A mixture of aromatic powders in the form of a cataplasm is much used as a mild rubefacient, especially in nausea and vomiting, being applied over the epigastrium. Such mixtures are commonly called *spiced plasters.* The following is a good formula. Take of ginger, cloves, cinnamon, and black pepper, each, in powder, an ounce; tincture of ginger half a fluidounce; honey a sufficient quantity. Mix the powders, and then add the tincture and honey, so as to form a stiff cataplasm.

Off. Prep. Confectio Aromatica; Confectio Opii; Pilulæ Aloës et Ferri; Pilulæ Cambogiæ; Pulvis Aloës Compositus. W.

PULVIS CATECHU COMPOSITUS. *Dub.* *Compound Powder of Catechu.*

"Take of Catechu, Kino, of each, *two ounces;* Cinnamon, Nutmeg, of each,

half an ounce. Reduce each to powder, mix, and pass through a fine sieve. When prepared, the powder should be kept in well stopped bottles." *Dub.*

This is an agreeable form for the administration of kino or catechu; but we do not see the propriety of mixing two substances so similar in their properties, at least in relation to taste and medicinal effect, that they may be considered identical. The dose is from fifteen to thirty grains.

Off. Prep. Confectio Catechu Composita. W.

PULVIS CRETÆ COMPOSITUS. *Lond., Ed., Dub. Compound Powder of Chalk.*

"Take of Prepared Chalk *half a pound;* Cinnamon *four ounces;* Tormentil, Gum Arabic, each, *three ounces;* Long Pepper *half an ounce.* Rub them separately into very fine powder, and then mix them." *Lond.*

"Take of Prepared Chalk *four ounces;* Cinnamon, in fine powder, *one drachm and a half;* Nutmeg, in fine powder, *a drachm.* Triturate them well together." *Ed.*

"Take of Prepared Chalk *five ounces;* Cinnamon *two ounces and a half;* Gum Arabic *two ounces;* Nutmeg *half an ounce.* Rub the ingredients separately to powder, then mix, and pass through a fine sieve." *Dub.*

In the Edinburgh preparation, the aromatics are in too small a quantity to serve any other purpose than to give an agreeable flavour to the chalk, which is the only active ingredient. The powder of the London and Dublin Colleges is, on the contrary, warm, stimulant, and astringent, as well as antacid; and is well calculated for diarrhœa, connected with acidity and without inflammatory symptoms. In such a combination, however, the proper proportion, and even the choice of the ingredients, vary so much with the symptoms, that they might with propriety be left to extemporaneous prescription. The dose is from ten to twenty grains, given in mucilage or sweetened water, and frequently repeated.

Off. Prep. Pulvis Cretæ Compositus cum Opio. W.

PULVIS CRETÆ COMPOSITUS CUM OPIO. *Lond.* PULVIS CRETÆ OPIATUS. *Ed., Dub. Compound Powder of Chalk with Opium.*

"Take of Compound Powder of Chalk *six ounces and a half;* Opium, in powder, *four scruples.* Mix them." *Lond.*

The *Dublin* process, though differently expressed, is identical in its results with the London.

"Take of Compound Chalk Powder *six ounces;* Powder of Opium *four scruples.* Triturate them together thoroughly." *Ed.*

The addition of the opium greatly increases the efficacy of the compound powder of chalk in diarrhœa; and its equal diffusion through the powder presents this advantage, that it may be conveniently given in minute doses applicable to infantile cases. Two scruples of the London or Dublin powder, and thirty-seven grains of the Edinburgh, contain a grain of opium. In the diarrhœa of adults from ten to twenty grains may be given for a dose, and repeated several times a day, or after each evacuation. W.

PULVERES EFFERVESCENTES. *Ed.* PULVERES EFFERVESCENTES TARTARIZATI. *Dub. Effervescing Powders.*

"Take of Tartaric Acid *one ounce;* Bicarbonate of Soda *one ounce and* 54 *grains,* or Bicarbonate of Potassa *one ounce and* 160 *grains.* Reduce the Acid and either Bicarbonate separately to fine powder, and divide each into sixteen powders. Preserve the acid and alkaline powders in separate papers of different colours." *Ed.*

The *Dublin College* takes *ten drachms* of the crystals of tartaric acid, and *eleven drachms* of bicarbonate of soda or *thirteen drachms* of bicarbonate of potassa, reduces them separately to powder, divides each into eighteen parts, and keeps the acid and alkaline powders in papers of different colours.

This is a formula, introduced into the last editions of the Edinburgh and Dublin Pharmacopœias, for a preparation which has been long in use under the name of *soda powders*. The common soda powders contain the ingredients in somewhat different proportions; consisting of twenty-five grains of the acid in one paper, and thirty of the bicarbonate in the other. They are always prepared with bicarbonate of soda; while the Pharmacopœias allow a choice between that and the bicarbonate of potassa. This want of precision is highly objectionable in officinal formulæ. If it was thought advisable that the practitioner should have the opportunity of prescribing either of these preparations at his option, they should have had different names.

The powders are administered in solution. An acid and an alkaline powder may be dissolved in separate portions of water and then mixed; or they may be thrown together, or successively into the same portion of water. The whole draught should be half a pint or somewhat less. It may be rendered more agreeable by adding two or three fluidrachms of syrup of ginger or orange peel to the water, before dissolving the powders. The rationale is simple. The tartaric acid seizes the alkali of the bicarbonate, forming a tartrate of soda or of potassa as the case may be, while the carbonic acid escapes with effervescence. The effervescing powders are refrigerant and very slightly laxative; and afford an agreeable and refreshing drink, suitable to febrile complaints. W.

PULVERES EFFERVESCENTES CITRATI. *Dub. Citrated Effervescing Powders.*

"Take of Crystals of Citric Acid *nine drachms;* Bicarbonate of Soda *eleven drachms*, or Bicarbonate of Potash *thirteen drachms*. Reduce the Acid and alkaline Bicarbonates, separately, to a fine powder, and divide each into *eighteen* parts. The acid and alkaline powders should be kept in papers of different colours." *Dub.*

The same remarks are applicable to these as to the preceding powders, and the same objection to the want of precision in the name. These powders, at least those made with the bicarbonate of potassa, are excellent diaphoretics, being identical in composition with the neutral mixture and effervescing draught. (See *Liquor Potassæ Citratis.*) W.

PULVIS IPECACUANHÆ ET OPII. *U. S.* PULVIS IPECACUANHÆ COMPOSITUS. *Lond., Ed., Dub. Powder of Ipecacuanha and Opium. Compound Powder of Ipecacuanha. Dover's Powder.*

"Take of Ipecacuanha, in powder, Opium, in powder, each, *a drachm;* Sulphate of Potassa *an ounce*. Rub them together into a very fine powder." *U. S.*

All the British Colleges employ the same ingredients as above, and in the same proportions. The *London*, having ordered them in the state of powder, simply directs them to be mixed together. The *Edinburgh* orders eight times the amount of the materials, and directs them to be triturated thoroughly together. The *Dublin* takes the opium and ipecacuanha in fine powder, mixes them thoroughly with the sulphate by trituration, and sifts them.

The sulphate of potassa in this preparation serves, by the hardness of its particles, to promote that minute division and consequent thorough intermixture of the opium and ipecacuanha, upon which the peculiar virtues of the compound depend. It also serves to dilute the active ingredients, and thus allow of their division into minute doses adapted to the complaints of children. This composition, though usually called Dover's powder, does not precisely correspond

with that originally recommended by Dr. Dover, which was prepared as follows. Four ounces of nitrate of potassa and the same quantity of sulphate of potassa were mixed in a red-hot crucible, and afterwards very finely powdered; one ounce of opium, sliced, was then added, and ground to powder with the saline mixture; lastly, an ounce of ipecacuanha and an ounce of liquorice root, in powder, were mixed with the other ingredients. This process was adopted in the former French Codex, and has been retained with little change in the present.

This powder is an admirable anodyne diaphoretic, not surpassed, perhaps, by any other combination in its power of promoting perspiration. Opium itself has a strong tendency to the skin, evinced both by the occasional diaphoresis, and by the itching and tingling sensation which it excites. While the vessels of the skin are stimulated by this ingredient, the secreting pores are relaxed by the ipecacuanha, and the combined effect is much greater than that which results from either separately. At the same time, the general stimulating influence of the opium, and its tendency to operate injuriously on the brain, are counteracted, so that the mixture may be given with safety in cases which might not admit of the use of opium alone. The preparation is applicable to all cases not attended with much fever or cerebral disease, or sick stomach, in which there is an indication for profuse diaphoresis, especially in painful affections, or those connected with unhealthy discharges. It is admirably adapted to the phlegmasiæ, particularly rheumatism and pneumonia, when complicated with a typhoid tendency, or after sufficient depletion. Under similar circumstances, it is useful in dysentery, diarrhœa, and the various hemorrhages, especially that from the uterus. It is sometimes also given in dropsy. In bowel affections, and whenever the hepatic secretion is deranged, it is frequently combined with small doses of calomel.

Ten grains of the powder contain one grain of opium. The dose is from five to fifteen grains, given diffused in water, or mixed with syrup, or in the form of bolus, and repeated at intervals of four, six, or eight hours, when it is desirable to maintain a continued diaphoresis. Its action may be materially promoted by warm drinks, such as lemonade, or balm tea, which, however, should not be given immediately after the powder, as they might provoke vomiting.

Off. Prep. Pilula Ipecacuanhæ cum Scillâ; Pilulæ Ipecacuanhæ et Opii. W.

PULVIS JALAPÆ COMPOSITUS. *U. S.*, *Lond.*, *Ed.*, *Dub.* *Compound Powder of Jalap.*

"Take of Jalap, in powder, *an ounce;* Bitartrate of Potassa, in powder, *two ounces.* Mix them." *U. S.*

The *London College* takes *three ounces* of jalap, *six ounces* of bitartrate of potassa, and *two drachms* of ginger; the *Dublin*, *two ounces* of jalap, *three ounces and a half* of bitartrate of potassa, and *half an ounce* of ginger. The *Edinburgh College* takes the same ingredients in the same proportion as the U. S. Pharmacopœia, and directs them to be rubbed together to a very fine powder.

The bitartrate, by being rubbed with the jalap, is thought to favour its more minute division, while it increases its hydragogue effect. A combination of these two ingredients, though with a larger proportion of cream of tartar (see *Jalapa*), forms a good cathartic in dropsy, and in scrofulous affections of the joints and glands. The dose of the officinal powder is from thirty grains to a drachm.

Off. Prep. Pulvis Scammonii Compositus. W.

PULVIS KINO COMPOSITUS. *Lond.* *Compound Powder of Kino.*

"Take of Kino *fifteen drachms;* Cinnamon *half an ounce;* dried Opium *a drachm.* Rub them separately to a very fine powder, and then mix them." *Lond.*

This is an anodyne astringent powder, useful in some forms of diarrhœa, but of which the composition would be better left to extemporaneous prescription, as the proportion of the ingredients should vary with the circumstances of the case. Twenty grains contain one grain of opium. The dose is from five grains to a scruple. W.

PULVIS RHEI COMPOSITUS, *Ed., Dub. Compound Powder of Rhubarb.*

"Take of Magnesia *one pound;* Ginger, in fine powder, *two ounces;* Rhubarb in fine powder, *four ounces.* Mix them thoroughly, and preserve the powder in well closed bottles." *Ed.*

The *Dublin College* uses the same ingredients in the same proportions.

This is a good laxative antacid, well adapted to bowel complaints, especially in children. The dose for an adult is from half a drachm to a drachm; for a child two or three years old, from five to ten grains. W.

PULVIS SALINUS COMPOSITUS. *Ed. Compound Saline Powder.*

"Take of Pure Muriate of Soda, Sulphate of Magnesia, each, *four ounces;* Sulphate of Potassa *three ounces.* Dry the salts separately with a gentle heat, and pulverize each; then triturate them well together, and preserve the mixture in well closed vessels." *Ed.*

This is an aperient powder, and may be given with advantage in costive habits, in the dose of two or three drachms, dissolved in half a pint of water or carbonic acid water, before breakfast. W.

PULVIS SCAMMONII COMPOSITUS. *Lond., Ed., Dub. Compound Powder of Scammony.*

"Take of Scammony, hard Extract of Jalap, each, *two ounces;* Ginger *half an ounce.* Rub them separately to a very fine powder; and then mix them." *Lond.*

The *Edinburgh College* takes *equal parts* of scammony and bitartrate of potassa; the *Dublin, an ounce* of scammony, and *three ounces* of compound powder of jalap.

It should be observed that the Edinburgh compound is essentially different from that of the London College; but we do not think that either of them is an eligible preparation. The cream of tartar in the former can serve little other purpose than to aid in the pulverization of the scammony, which requires no peculiar care in this respect. In the latter, though the ginger may tend to correct the griping property of the purgative ingredients, the extract of jalap too closely resembles the scammony in its operation to exert any important modifying influence upon it. The dose of the London powder is from ten to twenty grains, of the Edinburgh from fifteen to thirty. The Dublin powder is analogous in power to the Edinburgh, though somewhat weaker. W.

PULVIS TRAGACANTHÆ COMPOSITUS. *Lond., Ed. Compound Powder of Tragacanth.*

"Take of Tragacanth, in powder, Gum Arabic, in powder, Starch, each, *an ounce and a half;* Sugar [refined] *three ounces.* Rub the Starch and Sugar together to powder, then add the Tragacanth and Gum Arabic, and mix them all." *Lond.*

The *Edinburgh* process corresponds with the above.

This is applicable to the general purposes of the demulcents; but is chiefly employed in Great Britain as a vehicle for heavy insoluble powders. The dose is from thirty grains to a drachm. W.

QUINIA.

Preparations of Quinia.

QUINIÆ SULPHAS. *U. S.* QUINÆ DISULPHAS. *Lond.* QUINÆ SULPHAS. *Ed., Dub. Sulphate of Quinia.*

"Take of Yellow Bark, in coarse powder, *four pounds;* Muriatic Acid *three fluidounces;* Lime, in powder, *five ounces;* Water *five gallons;* Sulphuric Acid, Alcohol, Animal Charcoal, each, *a sufficient quantity.* Boil the Bark in one-third of the Water mixed with one-third of the Muriatic Acid, and strain through linen. Boil the residue twice successively with the same quantity of Water and Acid as before, and strain. Mix the decoctions, and, while the liquor is hot, gradually add the Lime, previously mixed with two pints of water, stirring constantly until the Quinia is completely precipitated. Wash the precipitate with Distilled Water, and, having pressed, dried, and powdered it, digest it in boiling Alcohol. Pour off the liquor, and repeat the digestion several times, until the Alcohol is no longer rendered bitter. Mix the liquors, and distil off the Alcohol, until a brown viscid mass remains. Upon this substance, removed from the vessel, pour about half a gallon of Distilled Water, and, having heated the mixture to the boiling point, add as much Sulphuric Acid as may be necessary to dissolve the impure alkali. Then add an ounce and a half of Animal Charcoal, boil for two minutes, filter the liquor while hot, and set it aside to crystallize. Should the liquor, before filtration, be entirely neutral, acidulate it very slightly with Sulphuric Acid; should it, on the contrary, change the colour of litmus paper to a bright red, add more Animal Charcoal. Separate the crystals from the liquor, dissolve them in boiling water slightly acidulated with Sulphuric Acid, add a little Animal Charcoal, filter, and set aside to crystallize. Wrap the crystals in bibulous paper, and dry them with a gentle heat. The mother waters may be made to yield an additional quantity of Sulphate of Quinia by precipitating the Quinia with Solution of Ammonia, and treating the precipitated alkali with distilled water, Sulphuric Acid, and Animal Charcoal, as before." *U. S.*

The *London College* has transferred this salt to its Materia Medica list.

"Take of Yellow Bark, in coarse powder, *one pound;* Carbonate of Soda *eight ounces;* Sulphuric Acid *half a fluidounce;* Purified Animal Charcoal *two drachms.* Boil the bark for an hour in four pints [Imperial measure] of water, in which half the Carbonate of Soda has been dissolved; strain, and express strongly through linen or calico; moisten the residuum with water and express again; and repeat this twice. Boil the residuum for half an hour with four pints of water and half the Sulphuric Acid; strain, express strongly, moisten with water, and express again. Boil the residuum with three pints of water and a fourth part of the Acid; strain and squeeze as before. Boil again the residuum with the same quantity of water and Acid, strain and squeeze as formerly. Concentrate the whole acid liquids to about a pint; let the product cool; filter it, and dissolve in it the remainder of the Carbonate of Soda. Collect the impure quinia on a cloth, wash it slightly, and squeeze out the liquor with the hand. Break down the moist precipitate in a pint of distilled water, add one fluidscruple of Sulphuric Acid, heat it to 212°, and stir occasionally. Should any precipitate retain its gray colour, and the liquid be neutral, add Sulphuric Acid drop by drop, stirring constantly, till the gray colour disappears. Should the liquid redden litmus, neutralize it with a little carbonate of soda. Should crystals form on the surface, add boiling distilled water to dissolve them. Filter through paper, preserving the funnel hot; set the liquid aside to crystallize; collect and squeeze the crystals; dissolve them in a pint of distilled water heated to 212°;

digest the solution for fifteen minutes with the Animal Charcoal; filter and crystallize as before. Dry the crystals with a heat not exceeding 140°. The mother liquors of each crystallization will yield a little more salt by concentration and cooling." *Ed.* The Imperial measure is employed in the above process.

The *Dublin College* exhausts the bark by maceration and decoction with water acidulated with sulphuric acid, concentrates the liquor, adds lime in excess, dries the precipitate partially on porous bricks and subjects it to powerful pressure in blotting paper, boils it repeatedly with rectified spirit, expresses, filters, distils off all the spirit, dilutes the brown viscid mass which remains, heats it to the boiling point, adds diluted sulphuric acid to neutralization or in slight excess, and finally, after treating the liquor with animal charcoal, sets it aside to cool and crystallize.

The present U. S. process, which is essentially that of the French Codex, differs from the one given in the Pharmacopœia of 1830, in the use of muriatic instead of sulphuric acid for acidulating the water first employed, and in the greater minuteness of the details. Both this and the French Codex process, as well as that of the Dublin College, are modifications of the plan originally proposed by M. Henry, jun., of Paris, for which he received a prize from the French Academy of Sciences, and which has been almost universally employed where alcohol is not too expensive. Henry's process, with all its details, may be found in previous editions of this work. An explanation of the several directions given in the U. S. Pharmacopœia will be useful to the student, by enabling him to comprehend each step of the process.

The yellow bark (Calisaya, or royal yellow) is the variety selected, because this contains quinia in the largest proportion, and most free from admixture with cinchonia. The alkali exists in the bark combined with kinic acid, and probably also with one or more of the colouring principles, as suggested by M. Henry. As in this latter state it is of difficult solubility, if it be not insoluble in water, the whole of the quinia cannot be extracted from the bark by means of that liquid alone. Berzelius, however, attributes the difficulty of exhausting the bark to the circumstance, that water converts the native neutral kinates into soluble superkinates which are dissolved, and insoluble subkinates which remain. By adding muriatic or sulphuric acid to the water in such quantities as to be in excess in relation to the quinia, the whole of the alkali combines with the acid to form a very soluble muriate or sulphate, in which state it exists, together with various impurities, in the decoctions procured by the first steps of the process. By the addition of lime to the filtered and mixed decoctions, the salt of quinia is decomposed, giving up its acid to the lime, while the quinia is liberated, and, being insoluble in water, is precipitated; the water retaining most of the impurities. If sulphuric acid was employed in the commencement of the process, sulphate of lime is deposited along with the quinia; but if muriatic acid was employed, the resulting chloride of calcium is retained in solution; and a reason is thus afforded for the preference of the latter acid. But, in either case, the excess of lime, and a compound formed of the lime and colouring matter, which is insoluble both in water and alcohol, are thrown down with the alkali. The precipitate having been washed in order to remove from it everything soluble in water, then pressed, dried, and powdered, the next step is to separate the quinia from the insoluble impurities. This is accomplished by the repeated action of alcohol, which dissolves the former, and leaves most of the latter behind. The whole of the alkali having been abstracted, the alcoholic solution of quinia is then concentrated so as to afford a brown viscid mass, which is impure quinia. Portions of this may be reserved, if thought advisable, for the preparation of other salts of quinia. The mass is treated with boiling distilled water acidulated with sulphuric acid, which forms a disulphate (the officinal sulphate)

with the quinia, and, being somewhat in excess, enables the salt to be readily dissolved. The animal charcoal now added should be the *unpurified* bone-black, the carbonate of lime contained in which neutralizes a portion of the sulphuric acid, and thus facilitates the crystallization of the sulphate of quinia when the solution cools. Should the quantity of the bone-black added be sufficient to render the solution quite neutral, so as in no degree to affect litmus paper, as much sulphuric acid should be added as will give the paper a slightly vinous tint; for otherwise the crystallization may commence before the liquor is completely filtered. If, on the contrary, the bone-black has been deficient, and the solution colours litmus paper cherry-red, more of that substance is to be added. This, however, is merely an incidental advantage of the animal charcoal; its chief use being to decolorize the liquid. The second crystallization is necessary to obtain the salt of quinia free from colour; and sometimes it cannot be rendered perfectly white without a third. It is essential that the heat employed in drying the crystals should be gentle, in order to prevent their efflorescence. The small quantity of cinchonia contained in Calisaya bark is extracted along with the quinia; but, as the sulphate of the former is more soluble than that of the latter, it remains in the mother liquors.*

According to M. Calvert, the proportion of sulphate of quinia obtained from bark is never certain when muriatic acid is employed as the solvent, and lime as the precipitant; for quinia is dissolved by a solution of chloride of calcium, and by lime-water; and a portion, therefore, remains in the liquid unprecipitated, which is greater when the lime employed is in excess. Having ascertained by trial that quinia is not dissolved by a solution of soda, and in scarcely appreciable proportion by chloride of sodium, he proposes to substitute this alkali for lime; first neutralizing the excess of acid by the carbonate, and then precipitating the quinia by caustic soda. (*Journ. de Pharm.*, 3*e sér.*, ii. 388.)

The Edinburgh process was contrived so as to avoid the use of alcohol, which is so costly in Great Britain as materially to affect the economy of the operation. The object of the first boiling with water and carbonate of soda is to get rid of the colouring principles, resin, and kinic acid, while the quinia is left behind. The residuum is next exhausted by means of water acidulated with sulphuric acid, which affords an impure solution of sulphate of quinia. This, after being sufficiently concentrated, is decomposed by carbonate of soda, which seizes the acid and precipitates the quinia with some colouring matter. The remaining steps of the operation are similar to those of the U. S. process, except that animal charcoal is employed only previous to the last crystallization; and the advantage incidentally obtained from it, of neutralizing the acid when in excess, is gained in the Edinburgh process by the use of carbonate of soda. Both Pereira and Christison speak favourably of this process.

Pelletier proposed to substitute oil of turpentine for alcohol in the ordinary process of procuring sulphate of quinia. The impure quinia, precipitated by lime from the acidulous decoctions, after being washed, pressed, and dried, is digested with the oil, which dissolves the quinia. The solution thus obtained is

* Mr. Weightman, of the firm of Powers and Weightman, manufacturing chemists of this city, informs us that the following modification of the above process has been found practically advantageous in their laboratory. The tincture obtained by acting with alcohol on the impure precipitated quinia, is neutralized with sulphuric acid in the distilling vessel; and the alcohol is then distilled off, leaving a viscid mass of impure sulphate, which is drawn off, and crystallizes on cooling. The mass thus obtained having been expressed, is dissolved in boiling water, to which purified animal charcoal has been added. The solution is filtered while hot, and then allowed to cool and crystallize. Another solution and crystallization is required to get the sulphate of quinia quite pure and white.—*Note to the tenth edition.*

agitated with water acidulated with sulphuric acid, by which the sulphate of quinia is formed. The oil separating, rises to the top, and is removed for future use; and the watery solution of the salt is evaporated, and treated as in the original process. A disadvantage, however, of this method is said to be that the oil does not completely exhaust the precipitate of its quinia.

According to the French Codex, 1000 parts of yellow bark ought to yield from 29 to 30 parts of sulphate of quinia, when treated by the process first described. Messrs. Powers & Weightman, who are probably among the largest manufacturers of sulphate of quinia in the world, inform us that they have usually obtained from 2·5 to 3 per cent. as an average product.

Sulphate of quinia may be obtained from other varieties of Peruvian bark by the above processes; and from some in considerable quantity; but most of them yield a much larger proportion of sulphate of cinchonia than the Calisaya; and this, being much more soluble than the sulphate of quinia, will remain dissolved in the residuary liquor after the crystallization of the latter. To obtain the *cinchonia* separate, the following method, originally suggested by Pelletier and Caventou, may be employed. Magnesia, lime, or a solution of potassa is added to the mother waters in excess.* The cinchonia is precipitated together with a portion of quinia which has remained in the solution, and with the excess of magnesia or lime, if one of these earths has been employed. The precipitate is collected on a filter, washed with hot water, then dried, and treated with boiling alcohol, which dissolves the organic alkalies. The alcoholic solution is filtered while hot, and the residue afterwards treated in the same manner with successive portions of alcohol, till quite exhausted. The solutions having been mixed, are concentrated by the distillation of the alcohol, and allowed to cool, when they deposit cinchonia in the crystalline state. Successive evaporations and refrigerations afford new crops of crystals, and the process should be continued till no more can be obtained. The cinchonia thus procured, if impure, should be reconverted into a sulphate and treated as before, animal charcoal being employed to free it from colour. The quinia remaining in the mother liquors, as it will not crystallize from alcohol, may be obtained by evaporation to dryness. To obtain the *sulphate of cinchonia*, mix the alkali with a small quantity of water, heat the mixture, and add gradually dilute sulphuric acid sufficient to saturate it; then boil with animal charcoal previously washed with muriatic acid, and filter the liquor while hot. Upon cooling it will deposit crystals of the sulphate, and, by repeated evaporation and crystallization, will yield all the salt which it holds in solution.†

When barks containing the newly discovered alkaloid *quinidia*, are used, as the sulphate of this base is much more soluble than that of quinia, it follows that, in the mother waters left after the crystallization of sulphate of quinia, there will be found a portion of sulphate of quinidia. In fact, there is generally, under these circumstances, more or less of the sulphates of the three

* Soda is probably a better precipitant, as it appears to be incapable of dissolving any quinia when employed in excess. (See *page* 1169.)

† A new mode of extracting quinia and other active vegetable principles has been proposed, which, if found as successful on trial as it is said to have been in the hands of its proposer, promises to supersede many of the processes now in use. From the experiments of M. Lebourdais, it would appear that purified animal charcoal has the property of abstracting from many vegetable products not only their colouring, but their sapid principles also, and afterwards of yielding the active matter uncombined to boiling alcohol, from which it is obtained by evaporation. M. Lebourdais deprived Peruvian bark of all its soluble principles by repeated maceration in alcohol of 0·923, filtered the resulting liquors, removed the alcohol by distillation, and mixed the liquid residue with a decoction made by boiling the same bark twice in distilled water. Acetate of lead was added to precipitate the resinous matter; and the liquor, having been filtered, was made to pass slowly through

alkaloids, quinia, cinchonia, and quinidia, all of which are contained in many barks; and, besides these, a portion of amorphous alkaloid, incapable of crys-

purified animal charcoal by which it was deprived of colour and taste. The charcoal was then washed, dried, and treated with alcohol of 0·848. The alcoholic solution thus obtained, upon being evaporated, yielded the quinia perfectly pure. (*Am. Journ. of Pharm.*, xxi. 92, from *Ann. de Chim. et de Phys.*) A chemist, however, who has tried this process, informs us, that he has not found it to answer well in practice.

We have been told that considerable quantities of a preparation have been imported from South America, consisting of a mixture of the alkaloids of bark in an impure state, obtained by forming acidulated decoctions of bark, precipitating with lime, treating the precipitate with alcohol, and evaporating the alcoholic solution. From this material the sulphates of quinia and cinchonia have been prepared on a large scale. It has sometimes yielded 25 per cent. of quinia converted into sulphate, and more than an equal quantity of cinchonia.—*Note to the eighth and tenth edition.*

Quinoidine. Precipitated Extract of Bark. Amorphous Quinia. Upon the evaporation of the mother liquor left after the crystallization of sulphate of quinia in the preparation of that salt, a dark-coloured substance is obtained, having the appearance of an extract. This was habitually employed by the late Dr. Emlen and one of the authors of this work, so early as about the year 1824, in the cure of intermittent fever, in which it proved equally effectual with the pure sulphate, though only about half as strong. It was adopted in the edition of the U. S. Pharmacopœia for 1830, under the name of "*impure sulphate of quinia*," but was abandoned in the edition of 1840, on account of the difficulty of ascertaining its purity. Sertürner supposed that he had discovered a new alkaline principle in this product; but his conclusions were invalidated by the experiments of MM. Henry and Delondre, which went to prove that the alkaline matter contained in it consisted of quinia and cinchonia, obscured by admixture with a yellowish substance that interfered with their crystallization. Nevertheless, under the name of *quinoidine* or *chinoidine*, given to the supposed new alkali by Sertürner, there has been long employed in Europe a substance precipitated from the mother liquor of sulphate of quinia by means of an alkaline carbonate, having a yellowish-white or brownish colour, and, when moderately heated, agglutinating into a mass of a resinous appearance. This substance was found by Dr. F. L. Winckler to contain an uncrystallizable alkaline principle, having the same combining weight as quinia, and differing from that alkali only in the want of the property of crystallization, and in forming uncrystallizable salts with the acids. (*Pharm. Cent. Blatt.* May, 1847, p. 310.) Liebig afterwards proved it to be identical in composition with ordinary quinia, to which he considers it as bearing the same relation that uncrystallizable sugar bears to the crystallizable. This substance has been found equally effectual with quinia in the cure of intermittents. In an economical point of view, it is highly important that it should be employed. It is sometimes sold under the name of *precipitated extract of bark*, and there can be little doubt that it enters into other preparations, which, under the name of extract of bark, have been put forth as peculiarly valuable for the cure of intermittents. It must not be confounded with the substance obtained by evaporating the mother liquors, which is of uncertain composition and strength. The chief objection to it is its liability to adulteration. The *amorphous quinia*, as Liebig calls it, is entirely soluble in dilute sulphuric acid and in alcohol; and, if its solution in a dilute acid yield upon the addition of ammonia exactly as much precipitate as there was of the original substance dissolved, it may be considered pure. (See *Am. Journ. of Pharm.*, xviii. 181.) We have been told that, in an extensive chemical manufacturing establishment in Philadelphia, since the introduction of steam heat, the loss by quinoidine in the preparation of sulphate of quinia has much diminished, showing the agency of heat in converting the crystallizable into the uncrystallizable salt.

M. Roder supposed that he had succeeded by the following process in converting amorphous quinia into the crystallizable. One part of commercial quinoidine, not previously precipitated by an alkali, was dissolved in four parts of alcohol of 0·865, and a solution of half a part of protochloride of tin in two parts of water added. The liquid was separated from the dark resinous deposit which formed, and was precipitated by ammonia. The precipitate was well washed, dried, and exhausted by alcohol; half the original quantity of protochloride of tin was added to the resulting liquid, which was again precipitated by ammonia; and the precipitate, well washed and dried, was exhausted by alcohol. A solution of pure quinia was thus obtained, which, saturated with sulphuric acid, yielded crystals of sulphate of quinia. M. Roder obtained from two different samples of quinoidine 40 and 43 per cent. of quinia, 10 and 9 per cent. of cinchonia, 30 and 28 per cent. of resin, and 20 per cent. of water; so that this product is somewhat more than half as strong as

tallization, probably resulting, in part at least, from the heat employed in the process. These may in a great degree be separated through their different solubilities in water. Sulphate of quinia being least soluble will first crystallize, afterwards the salt of quinidia, and finally that of cinchonia, which is the most soluble of the three; while the uncrystallizable salt will remain in solution, and may be obtained in the amorphous state by evaporation to dryness.

Properties. Sulphate of quinia is in fine silky, slightly flexible, needle-shaped crystals, interlaced among each other, or grouped in small star-like tufts. Its taste is intensely bitter, resembling that of the yellow bark. It effloresces slightly on exposure to the air, and, at a moderate heat, loses its crystalline form in consequence of the escape of its water of crystallization. At the temperature of 212° it becomes luminous, especially when rubbed. At about 240° it melts, assuming the appearance of wax. It is very slightly soluble in cold water, requiring, according to M. Baup, 740 parts at 54° F. for solution; while at the boiling point it is dissolved in thirty parts of water, which deposits it upon cooling. Its cold solution is opalescent. It is soluble in about 60 parts of cold alcohol of 0·835, but only to a very small extent in ether. The diluted acids, even tartaric and oxalic acids in excess, dissolve it with great facility. With an additional equivalent of sulphuric acid it forms another sulphate, which is more soluble in water than the officinal salt, and crystallizes from its solution with much greater difficulty. This is now generally believed to be strictly neutral, and therefore entitled to the name of sulphate of quinia; while the officinal salt is thought to contain two equivalents of base to one of acid, and is therefore properly a *subsulphate* or *disulphate of quinia.* The latter name has been adopted by the London College. In the U. S., Dublin, and Edinburgh Pharmacopœias, as well as in the French Codex, the name of sulphate of quinia, originally given to the officinal salt, under the impression that it was neutral, is still applied to it. Hence has arisen a confusion of nomenclature which must be embarrassing to the student. According to M. Baup, the proper sulphate, formerly called *supersulphate*, is soluble in 11 parts of water at 54° F., and in its own water of crystallization at the boiling point. It is very soluble in diluted, and somewhat less so in absolute alcohol. It may be obtained by adding to a boiling concentrated solution of the ordinary sulphate, as much sulphuric acid as already exists in the salt, and then evaporating the solution.

Composition. The officinal sulphate of quinia, the disulphate of chemists, is the only one used in medicine, and to this we have allusion in the present work, whenever sulphate of quinia is mentioned without any distinguishing epithet. In the crystalline form it is stated to consist of one equivalent of sulphuric acid 40, two eqs. of quinia 324, and eight eqs. of water 72=436. On exposure to the air, or to a heat of 212°, it effloresces, losing one-half of its water of crystallization (according to Soubeiran, six eqs.); and at 240° it loses one-half of the remainder, retaining two eqs. or about 4 per cent. of water, of which it cannot be deprived without decomposition. (*Phillips.*)*

pure quinia. (*Am. Journ. of Pharm.*, xxi. 49.) But we have been assured by Mr. Weightman, in relation to this process of M. Roder, that, if all the crystallizable matter has been previously separated from the mother waters, no crystals can afterwards be obtained by his method, though much uncrystallizable alkaline matter remains; showing that M. Roder had merely succeeded in more thoroughly separating the crystallizable portion, not in changing one form into the other.—*Note to the seventh, eighth, and tenth editions.*

* *Iodide of Sulphate (Disulphate) of Quinia.* This remarkable compound of officinal sulphate of quinia was discovered by Dr. Wm. Bird Herapath, of Bristol, England, who also investigated its singular optical properties. If to a solution of sulphate of quinia in a mixture of acetic acid and diluted alcohol, tincture of iodine be added by drops, and the mixture kept at 130° F. until perfect solution takes place, upon the cooling of the liquid, crystals will gradually form, which Dr. Herapath has found to consist of iodine,

Incompatibles and Tests. Sulphate of quinia is decomposed by the alkalies, their carbonates, and the alkaline earths. In solution, it affords white precipitates with potassa, soda, and ammonia, which are partly soluble in an excess of alkali. It is also precipitated by astringent infusions, the tannic acid of which forms a white insoluble compound with quinia. The soluble salts of lead and of baryta occasion precipitates; and that produced by the salts of baryta is insoluble in the acids. A freshly prepared solution of chlorine, added to a solution of the sulphate of quinia, and followed by the addition of water of ammonia, occasions an emerald-green colour, and, in certain proportions, the deposition of a green precipitate. If, instead of ammonia, a concentrated solution of ferrocyanuret of potassium be added, a dark-red colour is produced, which persists for several hours, but ultimately passes into green. This does not take place with cinchonia.

Adulterations. Sulphate of quinia has often been adulterated. Sulphate of lime, and other alkaline or earthy salts, gum, sugar, mannite, starch, stearin or margarin, caffein, salicin, and sulphate of cinchonia, are among the substances which are said to have been fraudulently added. By attending to the degree of solubility of the sulphate in different menstrua, and to its chemical relations with other substances already described, there can be little difficulty in detecting these adulterations. The presence of any mineral substance not readily volatilizable, may be at once ascertained by exposing the salt to a red heat, which will completely dissipate the sulphate of quinia, leaving the mineral behind. A volatile ammoniacal salt may be detected by the smell of ammonia emitted upon the addition of potassa. The absence of organic substances may be inferred, if pure cold concentrated sulphuric acid forms a colourless solution. Gum and starch are left behind by alcohol, and fatty matters by water acidulated with sulphuric acid. Sugar and mannite cause a solution of the salt in acidulated water to have a sweet taste, after the precipitation of the quinia by an alkaline carbonate. Salicin imparts the property of becoming red upon the contact of sulphuric acid; but, according to Pelletier, this change of colour does not take place unless the proportion of salicin exceeds one-tenth. If only in this proportion, the salicin must be isolated. To 1 part of the suspected salt, 6 parts of concentrated sulphuric acid may be added, and to the brown liquid which results, 125 parts of water. The salicin is thus separated, and may be obtained by filtration, in the form of a bitter white powder, becoming bright red with sulphuric acid. (See *Am. Journ. of Pharm.*, xvii. 156.) Caffein alters the solubility of the medicine in different menstrua. According to M. Calvert, a saturated solution of sulphate of quinia in cold water gives, with a solution of chloride of lime, a precipitate soluble in an excess of the latter; while a solution of sulphate of cinchonia of the same strength, treated in the same manner, gives a precipitate which is insoluble in a great excess of the reagent. The same effect is produced with lime-water, and solution of ammonia; and solution of chloride of calcium, while it

quinia, and sulphuric acid, probably combined in the state of iodide of sulphate of quinia. To obtain fine crystals various precautions are necessary, for which the reader is referred to the paper of Dr. Herapath. The crystals are of a brilliant emerald-green when viewed by reflected light; but almost colourless by transmitted light; and present a curious play of colours under varying circumstances of position. Their shape is very diversified, but traceable to the rhombic prism. They are dissolved by heated acetic acid and heated alcohol, and deposited on cooling. Their most remarkable property is that of polarizing light, in which they are equal if not superior to the tourmaline, for which they may be substituted with advantage in experiments in this branch of optics. As quinia is the only organic alkali which acts in this way, it is evident that the property may be resorted to as a means of detecting it, and especially of distinguishing it from cinchonia and quinidia. (*Pharm. Journ. and Trans.*, xi. 448 and 449, and xiii. 378. See also *Am. Journ. of Pharm.*, xxvi. 18.)—*Note to the tenth edition.*

furnishes a precipitate with a solution of sulphate of cinchonia, yields none with a solution of sulphate of quinia. (*Journ. de Pharm.*, 3e *sér.*, ii. 394.)* The Edinburgh College gives the following mode of testing the purity of sulphate of quinia. "A solution of ten grains in a fluidounce of distilled water and two or three drops of sulphuric acid, if decomposed by a solution of half an ounce of carbonate of soda in two waters [twice its weight of water], and heated till the precipitate shrinks and fuses, yields on cooling a solid mass, which when dry weighs 7·4 grains, and in powder dissolves entirely in solution of oxalic acid." According to the London College, "100 grains dissolved in diluted hydrochloric acid, yield, on the addition of chloride of barium, 26·6 grains of sulphate of baryta, dried at a red heat."

Medical Properties and Uses. Sulphate of quinia produces upon the system, so far as we are enabled to judge by observation, the same effects with Peruvian bark, without being so apt to nauseate and oppress the stomach. (See *Cinchona.*) Its effects upon the brain are even more striking than those of cinchona, probably because it is given in larger proportional doses. Even in ordinary doses, it often produces considerable cerebral disturbance, evinced by a feeling of tightness or distension in the head, ringing, buzzing, or roaring in the ears, hardness of hearing, &c. Some individuals are more liable to these effects than others, and in some even small doses produce them. A certain degree of this observable action on the brain is rather desirable than otherwise, as the evidence that the medicine is affecting the system. In very large quantities, as from a scruple to a drachm or more, besides the phenomena mentioned, it has been observed to occasion severe headache, vertigo, deafness, diminution or loss of sight, dilated and immovable pupil, loss of speech, general tremblings, intoxication or delirium, coma, and great prostration. In some instances the pulse has been remarkably diminished in frequency, down to fifty or even less in the minute. In an instance recorded by Giacomini, in which a man took by mistake about three drachms, the patient became insensible, and some hours afterwards was found by the physician in a state of general prostration, from which he recovered under the use of laudanum and aromatic waters. (*Ann. de Thérap.*, A. D. 1843, p. 176.) Besides its effects on the brain, sulphate of quinia sometimes occasions great gastric and intestinal irritation, marked by oppression at stomach, nausea, abdominal pains, vomiting, and purging. In general these effects of excessive doses gradually pass off, although partial deafness often continues for several days, and sometimes much longer. It is even said that permanent deafness has resulted. Though sulphate of quinia has been proved by the experiments of Dr. Baldwin, of Montgomery, Alabama, to be fatal to dogs, if prevented from being vomited by a ligature round the œsophagus, in quantities varying from fifteen or twenty grains to two drachms, with the symptoms of narcotic poisoning; yet we have seen no well authenticated case of death from its direct action on the healthy human subject. Given largely in disease, it has repeatedly

* Liebig's test of the presence of cinchonia is perhaps the simplest. Rub together fifteen grains of the suspected salt and two ounces of solution of ammonia, put the mixture into a flask, add two ounces of ether, and shake frequently. The quinia liberated by the ammonia is dissolved by the ether, while any cinchonia that may be present remains undissolved, floating between the ethereal solution above and the ammoniacal beneath. But M. O. Henry has shown that cinchonia is slightly soluble in ammonia, so that a small portion might escape detection. It has, therefore, been proposed to modify the test by heating the mixture of the suspected salt and ammonia, so as almost entirely to drive off the excess of this alkali, and then to add the ether. If the liquid now remain quite transparent, without any turbid layer between the upper and lower stratum, it may be inferred that no cinchonia is present. For papers on this subject, see the *Journ. de Pharm.* (3e *sér.* xiii. 102, xvi. 327, and xxi. 284), and *Am. Journ. of Pharm.* (xx. 231, and xxiv. 166). For a method of detecting the presence of *quinidia* also in sulphate of quinia, the reader is referred to a note in the first part of this work, *page* 258.

caused fatal results, not so much however by its peculiar action, as by co-operating with the disease in establishing intense local irritation or inflammation, especially in the brain. Though capable, therefore, of doing mischief if improperly used, sulphate of quinia can scarcely be ranked among the poisons.

From its occasional effect in diminishing the frequency of the pulse and the general strength, it has been supposed to be essentially sedative in large doses. Such an opinion, unless well founded, might lead to hazardous practice. The probability is that the apparently sedative effect upon the circulation arises from an overwhelming stimulant influence upon the cerebral centres, whereby the system is deprived of the support of these centres, and the heart's action is depressed with other organic functions. Similar effects may be obtained from excessive doses of most of the cerebral stimulants. Examination of the brain in the lower animals, after death from quinia, has shown great congestion of that organ and its membranes, and even meningitis. (See *Am. Journ. of Med. Sci.*, xix. 197.) In the present state of our knowledge, therefore, it is safest to consider sulphate of quinia as a direct and powerful stimulant to the brain. It probably operates through the circulation, as there is no doubt that it is absorbed, the alkaloid having been found unchanged in the urine.

Sulphate of quinia may be substituted for cinchona in all diseases to which the latter is applicable; and, in the treatment of intermittents, has almost entirely superseded the bark. It has the advantage over that remedy, not only that it is more easily administered in large doses, and more readily retained by the stomach, but that, in cases which require an impression to be made through the rectum or the skin, it is much more effectual; because, from the smallness of its bulk, it is more readily retained in the former case, and more speedily absorbed in the latter. Still we cannot be certain that there are not other active principles in bark besides the quinia and cinchonia, the latter of which possesses properties analogous to those of the former; nor that the mode of combination in which these principles exist, may not in some measure modify their therapeutic effects. The question can be solved only by careful and long-continued observation. In the mean time, we may resort to the bark if the sulphate of quinia should not answer the ends in view; and instances have occurred, under our own notice, in which it has proved successful in intermittents after the salt has failed.

Sulphate of quinia may be given in pill or solution, or suspended in water by the intervention of syrup and mucilage. The form of pill is usually preferred. (See *Pilulæ Quiniæ Sulphatis.*) The solution may be readily effected by the addition of a little acid of almost any kind to the water. Eight grains of the sulphate will dissolve in a fluidounce of water, acidulated with about twelve minims of the diluted sulphuric acid, or aromatic sulphuric acid of the Pharmacopœias; and this is the most eligible mode of exhibiting the medicine in the liquid form. The addition of a small proportion of sulphate of morphia or of laudanum will often be found advantageous, when the stomach is disposed to be sickened, or the bowels to be disturbed by the quinia. Dr. R. H. Thomas, of Baltimore, has found that one part of tannic acid will deprive five parts of sulphate of quinia of bitterness, without impairing its medicinal efficacy. (*Am. Journ. of Med. Sci.*, N. S., xix. 541.) It is obvious that tannate of quinia is thus formed; and as this, though insoluble in water, is readily dissolved in dilute acids, and consequently in the gastric liquor when acid, there can be no doubt that it will generally prove efficacious. It may, however, happen that the stomach may be quite free from acid, and that the operation of this salt may prove less certain than that of the sulphate; and such is asserted to have been the case in some instances. But a little lemonade taken after the medicine would probably obviate the difficulty.

Twelve grains of sulphate of quinia are equivalent to about an ounce of good bark. The dose varies exceedingly, according to the circumstances of the

patient and the object to be accomplished. As a tonic simply, a grain may be given three or four times a day, or more frequently in acute cases. In intermittents, from twelve to twenty-four grains should be given between the paroxysms, divided into smaller or larger doses according to the condition of the stomach, or the length of the intermission. From one to four grains may be given at once, and some even advise the whole amount. In malignant intermittents and remittents, the quantity may be increased to thirty grains or even a drachm between the paroxysms. M. Maillot gave one hundred and twenty-eight grains, in the course of a few hours, in a case of malignant fever occurring in Northern Africa, with the happiest results. The caution, however, is necessary, not to employ this heroic practice against easily conquerable diseases. Very large doses of the sulphate have recently been given in acute rheumatism, and with great asserted success; but the occurrence of at least one fatal case from inflammation of the brain should lead to some hesitation in this employment of the remedy. When the stomach will not retain the medicine, it may be administered with nearly as much efficacy by enema; from six to twelve grains, with two fluidounces of liquid starch, and from twenty to forty drops of laudanum, being injected into the rectum, in ordinary cases, every six hours. Should circumstances render this mode of application impracticable, an equal quantity, diluted with arrow-root or other mild powder, may be sprinkled, at the same intervals, upon a blistered surface denuded of the cuticle. The epigastrium, or the inside of the thighs and arms, would be the proper place for the blister. The sulphate has also been employed by friction in the form of ointment, in cases of malignant intermittent. The ointment should be made by incorporating a saturated alcoholic solution of the salt with lard, and should be applied to the inside of the thighs and arms. It is said that quinia is more readily absorbed when united with a fatty acid. This union may be effected by mixing solutions of soap and of a salt of quinia. The quinia soap is precipitated.

Solutions of sulphate of quinia have been advantageously employed as local applications to indolent ulcers, and chronic mucous inflammations. (Wedderburn and Fearn, *New Orleans Med. and Surg. Journ.*, iii. 161 and 341.)

QUINÆ MURIAS. *Dub.* *Muriate of Quinia.*

"Take of Sulphate of Quinia *one ounce* [avoirdupois]; Chloride of Barium *one hundred and twenty-three grains;* Distilled Water *thirty-two* [*fluid*] *ounces.* Dissolve the Chloride of Barium in two [fluid] ounces of the Water, and the Sulphate of Quinia in the remainder, raised to the temperature of ebullition. Mix the two solutions, evaporate to one-half, filter, and continue the evaporation by means of a steam or water heat, until crystalline spicula begin to appear. The solution is now to be permitted to cool, and the crystals which separate to be dried on blotting paper. The liquor decanted off the crystals will, by further concentration and cooling, yield an additional product." *Dub.*

The only advantage of this salt of quinia over the sulphate is its greater solubility; and this is scarcely worth the trouble of the process, especially as the latter salt may be so readily rendered soluble by the addition of an acid. The dose is the same as that of the sulphate, to which the reader is referred. (See *Quiniæ Sulphas.*)

Off. Prep. Quinæ Valerianas. W.

QUINÆ VALERIANAS. *Dub.* *Valerianate of Quinia.*

"Take of Muriate of Quinia *seven drachms* [Dub. weight]; Valerianate of Soda *one hundred and twenty-four grains;* Distilled Water *sixteen* [*fluid*] *ounces.* Dissolve the Valerianate of Soda in two ounces, and the Muriate of Quinia in the remainder of the Water, and, the temperature of each solution being raised

to 120°, but not higher, let them be mixed, and let the mixture be set by for twenty-four hours, when the valerianate of quinia will have become a mass of silky acicular crystals. Let these be pressed between folds of blotting paper, and dried without the application of artificial heat." *Dub.*

This is a case of double decomposition between the two salts employed, resulting in the production of chloride of sodium which remains in solution, and of valerianate of quinia which crystallizes. This salt has a strong and adhesive odour of valerianic acid, which is very repulsive, and quite distinct from that of oil of valerian. It is soluble in water, more so in that liquid at a somewhat elevated temperature than when cold, and is deposited from its warm solution in fine crystals on cooling. In boiling water it melts into oily globules, and undergoes decomposition, with the escape of valerianic acid; and the Dublin College directs that its solution shall not be heated above 120°. Even at common temperatures it is probably undergoing a constant, though slow loss of the acid, of which it smells so strongly. It is soluble in alcohol. We are unacquainted with any special virtues in this salt. It may, however, be given in the dose of a grain or two repeated several times a day, in cases of debility attended with nervous disorder. A combination of Peruvian bark and valerian has long been known as peculiarly efficacious in hemicrania. Perhaps the valerianate of quinia may be used advantageously in the same affection. W.

SODA.

Preparations of Soda.

LIQUOR SODÆ. *Lond.* SODÆ CAUSTICÆ LIQUOR. *Dub. Solution of Soda. Solution of Caustic Soda.*

"Take of Carbonate of Soda *thirty-one ounces;* Lime *nine ounces;* boiling Distilled Water *a gallon* [Imp. meas.]. Prepare this Solution in the manner directed for Liquor Potassæ." *Lond.* The specific gravity of this Solution is 1·061.

The *Dublin College* takes *two pounds* [avoirdupois] of crystallized carbonate of soda, *ten ounces* [avoird.] of fresh burnt lime, and *a gallon and seven fluid-ounces* [Imp. meas.] of distilled water, and proceeds precisely in the manner directed for obtaining solution of potassa. The phraseology of the two formulæ is the same. The resulting Solution is stated to have the specific gravity of 1·056.

Solution of soda is prepared in the same way as solution of potassa. By a double decomposition between carbonate of soda and hydrate of lime, there are formed hydrate of soda in solution, and carbonate of lime which precipitates. In both the processes an excess of lime is used, which is necessary to insure a full decomposition of the carbonate.

Properties, &c. Solution of soda, commonly called solution of *caustic* soda, is a new officinal of the Dublin Pharmacopœia of 1850, and the London of 1851. It is a colourless liquid, having a caustic taste and alkaline reaction. Its properties and tests are the same as those of solution of potassa, with the exception that no precipitate is produced by chloride of platinum or tartaric acid. The London solution is somewhat stronger than the Dublin, and contains four per cent. of soda. The alkali dissolved must be viewed as hydrate of soda, consisting of one eq. of soda 31·3, and one of water 9=40·3.

Solution of soda is used by the London College as a chemical agent for preparing oxysulphuret of antimony, and by the Dublin College for saturating valerianic acid in forming valerianate of soda.

Off. Prep. Sodæ Valerianas. B.

SODÆ CARBONAS EXSICCATUS. *U. S.* SODÆ CARBONAS EXSICCATA. *Lond.* SODÆ CARBONAS SICCATUM. *Ed., Dub. Dried Carbonate of Soda.*

"Take of Carbonate of Soda *a convenient quantity.* Expose it to heat, in a clean iron vessel, until it is thoroughly dried, stirring constantly with an iron spatula; then rub it into powder." *U. S.*

The *London College* takes *a pound* of the salt, exposes it to heat until the crystals fall to pieces, then subjects it to a red heat, and finally rubs it to powder. The *Edinburgh College* heats any convenient quantity in a shallow vessel till it is dry, then urges it with a red heat in a crucible, and reduces it to powder when cold.

"Take of Crystallized Carbonate of Soda of Commerce *any convenient quantity.* Expose it in a porcelain capsule to a pretty strong sand heat, until the liquid which first forms is converted into a dry cake, and having rubbed this to powder, enclose it in a bottle." *Dub.*

Carbonate of soda contains ten equivalents of water of crystallization, and when heated, readily undergoes the watery fusion. Upon continuing the heat, the water is dried off, and a white porous mass remains, which is easily reduced to powder. The London and Edinburgh Colleges expose the dry mass to a red heat before powdering it. Dried carbonate of soda is in the form of a white powder, and differs in no respect from the crystallized carbonate, except in being devoid of water of crystallization. (See *Sodæ Carbonas.*) When decomposed by dilute sulphuric acid, it evolves 40·7 per cent. of carbonic acid. (*Lond. Pharm.*)

Medical Properties and Uses. This preparation was introduced into practice by Dr. Beddoes, who extolled its virtues in calculous complaints. It is applicable to the cure of such affections, only when dependent on a morbid secretion of uric acid. Its advantage over the common carbonate is that it admits of being made into pills, in consequence of being in the dried state. As the water of crystallization forms more than half of the carbonate, the dose of the dried salt must be reduced in proportion. From five to fifteen grains may be given three times a day in the form of pill, prepared with soap and aromatics. The general medical properties of this salt have been given under the head of *Sodæ Carbonas.*

Off. Prep. Sodæ Bicarbonas. B.

SODÆ CARBONATIS LIQUOR. *Dub. Solution of Carbonate of Soda.*

"Take of Crystallized Carbonate of Soda of Commerce *one ounce and a half* [avoirdupois]; Distilled Water *one pint* [Imp. meas.]. Dissolve and filter. The specific gravity of this Solution is 1·026." *Dub.*

This preparation furnishes a solution of carbonate of soda of determinate strength, each Imperial fluidounce of which contains nearly thirty-three grains of the salt. It is convenient for prescribing the alkali in solution, and for forming effervescing draughts, each fluidounce being saturated, on an average, by half a fluidounce of lemon juice. The dose is from one to two tablespoonfuls, sufficiently diluted with water, and given two or three times a day. B.

SODÆ BICARBONAS. *U.S., Lond., Ed., Dub. Bicarbonate of Soda.*

"Take of Carbonate of Soda, in crystals, *a convenient quantity.* Break the crystals in pieces, and put them into a wooden box, having a transverse partition near the bottom pierced with numerous small holes, and a cover which can be tightly fitted on. To a bottle having two tubulures, and half filled with water,

adapt two tubes, one connected with an apparatus for generating carbonic acid and terminating under the water in the bottle, the other commencing at the tubulure in which it is inserted, and entering the box by an opening near the bottom, beneath the partition. Then lute all the joints, and cause a stream of carbonic acid to pass through the water into the box until the carbonate of soda is fully saturated. Carbonic acid is obtained from Marble by the addition of dilute sulphuric acid." *U. S.*

In the *London Pharmacopœia* of 1851, bicarbonate of soda has been transferred from the Preparations to the list of Materia Medica.

"Fill with fragments of Marble a glass jar, open at the bottom and tubulated at the top; close the bottom in such a way as to keep in the Marble without preventing the free passage of a fluid; connect the tubulature closely by a bent tube and corks with an empty bottle, and this in like manner with another bottle, filled with one part of Carbonate of Soda and two parts of Dried Carbonate of Soda well triturated together; and let the tube be long enough to reach the bottom of the bottle. Before closing the last cork closely, immerse the jar to the top in diluted muriatic acid, contained in any convenient vessel; when the whole apparatus is thus filled with carbonic acid gas, secure the last cork tightly; and let the action go on till next morning, or till the gas is no longer absorbed by the salt. Remove the damp salt which is formed, and dry it, either in the air without heat, or at a temperature not above 120°." *Ed.*

"Take of Crystallized Carbonate of Soda of Commerce *two pounds* [avoirdupois]; Distilled Water *one quart* [two pints Imp. meas.]; Muriatic Acid of Commerce *one pint and a half* [Imp. meas.]; Water *three pints* [Imp. meas.]; Chalk, in fragments, *one pound* [avoird.], or *a sufficient quantity*. Having diluted the Muriatic Acid with the Water, and dissolved the Carbonate of Soda in the Distilled Water, manipulate with these solutions, and with the Chalk, as directed in the formula for *Potassæ Bicarbonas*, employing also the arrangement of apparatus there described. With the view, however, of obtaining from the mother liquor an additional quantity of Bicarbonate, it is not necessary that the evaporation shall be preceded by a filtration." *Dub.*

The object of these processes is to unite the soda with an additional equivalent of carbonic acid, whereby it becomes converted into the bicarbonate.

The process adopted in the U. S. Pharmacopœia since 1840, is that which has been practised for many years in the United States, and which was described in 1830, by Dr. Franklin R. Smith, in the first volume of the Journal of the Philadelphia College of Pharmacy. This process is attributed to Dr. Smith by Soubeiran, who characterizes it as the best that can be employed. (*Nouv. Traité de Pharm.*) It was adopted in the French Codex on its revision of 1837. A stream of carbonic acid is passed into a suitable vessel, containing the crystallized carbonate placed on a diaphragm, pierced with numerous holes. As the bicarbonate combines with much less water of crystallization than is contained in the carbonate, it follows that, during the progress of the saturation of the carbonate, a considerable quantity of water is liberated. This water would finally dissolve the bicarbonate formed, were it not for the pierced diaphragm, through which it is allowed to drain off, holding in solution a part of the carbonate. When the saturation is completed, the pieces of crystals, still supported on the diaphragm, are found to have retained their original form, but to have become opaque and of a porous texture. The necessary carbonic acid for forming the bicarbonate may be economically obtained from other processes in which this acid is evolved; as, for example, from the process for making tartaric acid, in which tartrate of lime is formed from cream of tartar by the addition of carbonate of lime.

The process adopted in the last Edinburgh Pharmacopœia is that of Berzelius.

In the U.S. process, the excess of water over the quantity necessary for the bicarbonate is allowed to drain off; but it holds a certain portion of carbonate in solution, which thus escapes the action of the carbonic acid. To avoid this result it is only necessary to prepare a carbonate containing just sufficient water of crystallization to accommodate the bicarbonate; and the process recommended by Berzelius accomplishes that purpose. Thus, the salt which he prepares to be submitted to the carbonic acid, is an intimate mixture, in fine powder, of four parts of effloresced carbonate, with one of the crystallized salt. The proportion adopted by the Edinburgh College is different, namely, two parts of the dried carbonate to one of the crystallized carbonate; and is such as to afford a slight excess of water over that required to constitute the bicarbonate. Hence the Edinburgh process furnishes a damp salt, which is dried in the air without heat, or at a temperature not exceeding 120°. The apparatus employed by the College for obtaining the carbonic acid is precisely the self-regulating generator, devised by Dr. Hare on the principle of Gay-Lussac's. The empty bottle, placed between the generating apparatus and that containing the salt, is intended to detain any impurity which may be carried over with the stream of carbonic acid.

The Dublin College, in its Pharmacopœia of 1850, has adopted the process of dissolving the carbonate in water before submitting it to the action of the carbonic acid. The solution, when saturated, lets fall the sparingly soluble bicarbonate in minute crystals, which are washed, drained, and dried as directed for bicarbonate of potassa. A second crop of crystals is obtained from the mother water without filtration, by evaporating it to one-half by a heat not exceeding 110°.

Artus has given a process for obtaining bicarbonate of soda, similar to that of Wöhler for forming the corresponding salt of potassa. (See *Potassæ Bicarbonas.*) In this process, the effloresced carbonate, mixed with half its weight of freshly ignited and finely powdered charcoal, is saturated by a stream of carbonic acid, derived from the fermentation of sugar. The presence of the charcoal greatly promotes the absorption. (*Pharm. Cent. Blatt*, 1843, p. 254.)

Properties, &c. As obtained by the U.S. formula, bicarbonate of soda is in opaque, porous masses, made up of numerous, aggregated crystalline grains, and having a snow-white colour. For the convenience of the apothecary these masses are reduced to powder. As procured by the Edinburgh process, it is in small, white, opaque, irregular scales. The Dublin preparation is in minute, colourless, indistinct crystals. Bicarbonate of soda is permanent in the air, and slightly alkaline to the taste and to turmeric paper. It is soluble in thirteen parts of cold water. When the solution is exposed to heat, the salt gradually parts with carbonic acid, and, at the temperature of 212°, is converted into sesquicarbonate. At a red heat, the water of crystallization and the second equivalent of carbonic acid, amounting together to 37 per cent., are expelled, and the anhydrous carbonate is left. One eq., or 84·3 parts of the crystallized bicarbonate should lose, on complete decomposition by dilute sulphuric acid two eqs. or 44 parts of carbonic acid, equal to 52·1 per cent. The salt is seldom so perfect as to satisfy this test; as good commercial samples generally contain from two to three per cent. of carbonate. The note of tests of the London Pharmacopœia calls for the presence of 51·7 per cent. of carbonic acid, which is very near the theoretical quantity. The presence of carbonate may be known by a decided alkaline taste and reaction, by a cold solution of the salt yielding a precipitate with sulphate of magnesia, and by a solution in 40 parts of water, affording, without agitation, an orange-coloured or reddish-brown precipitate with corrosive sublimate; whereas the pure salt produces a slight opalescence only with this test. The corrosive sublimate test is adopted in the Edinburgh Pharmacopœia, and, according to Dr. Christison, readily detects one per cent. of carbonate. The pure bicarbonate is

not precipitated by chloride of platinum, or, when supersaturated with nitric acid, by chloride of barium or nitrate of silver. The non-action of these tests shows the absence of salts of potassa, and of sulphates and chlorides. The incompatibles of this salt are the same as those of the carbonate, except sulphate of magnesia in the cold, which decomposes the carbonate, but not the bicarbonate.

Composition. Bicarbonate of soda, when perfect, consists of two eqs. of carbonic acid 44, one of soda 31·3, and one of water 9=84·3. The London College formerly prepared this salt by a faulty process, and gave it the name of sesquicarbonate. In its Pharmacopœia of 1851, it has placed the salt, under the correct name of bicarbonate, in the catalogue of Materia Medica; where, perhaps, it properly stands, as it is now prepared in great perfection on a large scale.

Medical Properties. This salt has the general medical properties of the carbonate; but, from its mild taste and less irritating qualities, proves more acceptable to the palate and stomach. It is often resorted to in calculous cases, characterized by predominant uric acid. When the carbonate is given in these cases, its continued use is liable to induce phosphatic deposits, after the removal of the uric acid. According to D'Arcet, who made the observation at the springs of Vichy, this objection does not lie to the bicarbonate, especially when taken in carbonic acid water; for this salt, by its superabundant acid has the power of maintaining the phosphates in solution, even after the alkali has caused the uric acid to disappear. The same remark is applicable to the bicarbonate of potassa. Bicarbonate of soda has been given in infantile croup, with apparent advantage in promoting the expulsion of the false membrane, in the dose of a grain every five minutes, dissolved in milk and water. Dr. Lemaire has proposed it as an antiphlogistic remedy in the treatment of pneumonia, membranous angina, and croup, supposing it to act on the principle of removing from the blood the excess of fibrin, a morbid condition which is supposed to characterize that liquid in local inflammations. The dose for an adult is from ten grains to a drachm, and is taken most conveniently in a glass of carbonic acid water. This salt is principally consumed in making soda and Seidlitz powders. (See *pages* 53 and 54.) It is sometimes made into lozenges. (See *Trochisci Sodæ Bicarbonatis.*)

Off. Prep. Pulveres Effervescentes; Pulveres Effervescentes Citrati; Sodæ Aqua Effervescens; Trochisci Sodæ Bicarbonatis. B.

SODÆ AQUA EFFERVESCENS. *Ed.* *Effervescing Water of Soda.*

"Take of Bicarbonate of Soda *one drachm;* Water *one pint* [Imp. meas.]. Dissolve the Bicarbonate in the Water, and saturate it with carbonic acid under strong pressure. Preserve the liquid in well closed vessels." *Ed.*

This is a solution of bicarbonate of soda in carbonic acid water, in the proportion of three grains to the Imperial fluidounce. The name given to it is incorrect. The reason is not obvious why this solution is made with water, and the corresponding one of potassa with distilled water. B.

LIQUOR SODÆ CHLORINATÆ. *U.S., Lond.* SODÆ CHLORINATÆ LIQUOR. *Dub.* *Solution of Chlorinated Soda.* *Solution of Chloride of Soda.* *Labarraque's Disinfecting Liquid.*

"Take of Chlorinated Lime *a pound;* Carbonate of Soda *two pounds;* Water *a gallon and a half.* Dissolve the Carbonate of Soda in three pints of the Water, with the aid of heat. To the remainder of the Water add, by small portions at a time, the Chlorinated Lime previously well triturated, stirring the mixture after each addition. Set the mixture by for several hours that the dregs may subside; then decant the clear liquid, and mix it with the solution of Carbonate of Soda. Lastly, decant the clear liquor from the precipitated carbonate

of lime, pass it through a linen cloth, and keep it in bottles secluded from the light." *U. S.*

"Take of Carbonate of Soda *a pound;* Distilled Water *forty-eight fluidounces* [Imp. meas.]; Chloride of Sodium *four ounces;* Binoxide of Manganese *three ounces;* Sulphuric Acid *two fluidounces and a half.* Dissolve the Carbonate in two pints [Imp. meas.] of Water. Then put the Chloride and Binoxide, rubbed to powder, into a retort; and add to them the Acid, previously mixed with three fluidounces of Water, and cooled. Heat the mixture, and pass the chlorine first through five fluidounces of Water, and afterwards into the solution of the Carbonate above directed." *Lond.*

"Take of Chlorinated Lime *half a pound* [avoirdupois]; Water *half a gallon* [Imp. meas.]; Crystallized Carbonate of Soda of Commerce *seven ounces* [avoird.]. Blend well by trituration in a mortar the Chlorinated Lime with three pints of the Water, and, having transferred the mixture to a stoppered bottle, let this be well shaken several times for the space of three hours. Pour out the contents of the bottle on a calico cloth, and to the filtered solution add the Carbonate of Soda, dissolved in the remaining pint of Water. Having stirred the mixture well for ten minutes, separate the liquid by a second filtration, and preserve it in a well stopped bottle. The specific gravity of this liquid is 1·034." *Dub.*

This solution was first brought into notice as a disinfecting agent by Labarraque, an apothecary of Paris. It was afterwards found to possess valuable therapeutic properties. The process of the *U. S.* Pharmacopœia is that of Payen, adopted in the French Codex of 1837. It consists in decomposing a solution of carbonate of soda by one of chlorinated lime. Carbonate of lime is precipitated and the chlorinated soda remains in solution. The proportion employed gives an excess of carbonate of soda, the presence of which renders the solution more permanent. The process of the Dublin College for this newly adopted officinal is the same in principle as that of the U. S. Pharmacopœia; but the proportions employed are different. While the U. S. process gives an excess of carbonate of soda, the Dublin formula orders a proportion so small as not to be sufficient to decompose the whole of the chlorinated lime, even assuming this to be of inferior quality. The water taken is not much more than half that ordered in the U. S. Pharmacopœia; from which it follows that the Dublin solution is denser. In consequence of the chlorinated lime being taken in excess, the Dublin preparation must be a mixed aqueous solution of chlorinated soda and chlorinated lime. The London process is that of Labarraque. All the chlorine generated from the prescribed quantity of materials for forming that gas, is passed into the solution of carbonate of soda; and when the chlorine gas is limited to this quantity, no carbonic acid is disengaged. The chlorine is first passed through water to free it from muriatic acid, which, if suffered to come over, would convert the alkali into common salt.

Properties. The *U. S.* solution is a colourless liquid, having an alkaline reaction, and a faint smell of chlorine. With lime-water it yields a precipitate of carbonate of lime, known as a carbonate by its dissolving with effervescence in an acid. This precipitate is caused by the excess of carbonate of soda. Owing to the presence of loosely combined chlorine, it rapidly destroys the colour of sulphate of indigo. The *London* solution has a pale-yellow colour, and a sharp saline, astringent taste. The colour of turmeric is first rendered brown, and afterwards destroyed. When it is boiled, chlorine is not given off, nor is its bleaching property sensibly impaired; and, when carefully evaporated, a mass of damp crystals is obtained, which, when redissolved in water, possess the properties of the original liquid. Upon the addition of muriatic acid, both these solutions emit carbonic acid and chlorine together, the former known by its pre-

cipitating lime from lime-water, the latter by its decolorizing power on sulphate of indigo. The *Dublin* solution is peculiar in containing no undecomposed carbonate of soda. It therefore has not an alkaline reaction, is not precipitated by lime-water, and does not emit carbonic acid on the addition of an acid. All three solutions, when exposed to the air, absorb carbonic acid, and slowly evolve chlorine. It is on this property of gradually evolving chlorine that their disinfecting power depends.

Nature and Composition. The chemical nature of these solutions is different. Assuming the chlorinated lime to be essentially hypochlorite of lime with chloride of calcium (see *page* 156), the U. S. solution will contain *hypochlorite of soda* with *chloride of sodium*. Besides these there will be present more or less *carbonate of soda*, according as there happens to be in the chlorinated lime less or more chlorine to decompose it. In all cases, however, there will be an excess of carbonate; as the best chlorinated lime does not contain sufficient chlorine to effect its entire decomposition, in the proportion in which it is taken in the formula. The constitution of the London preparation is more complicated. As it is a peculiarity in its formation that no carbonic acid is evolved, it is necessary to assume the presence of all the carbonic acid of the carbonate of soda; and hence it is considered to be a combination of *hypochlorite of soda*, *chloride of sodium*, and *bicarbonate of soda*. The reaction is supposed to take place between four eqs. of carbonate of soda and two of chlorine. By a transfer of carbonic acid from two eqs. of carbonate to the remaining two eqs. of the same salt, two eqs. of bicarbonate are formed, and two of soda left. The sodium and oxygen of one eq. of soda, unite, each, with one eq. of chlorine, so as to form one eq. of chloride of sodium, and one of hypochlorous acid. This acid then unites with the remaining eq. of soda to form hypochlorite of soda. The view here taken makes the U. S. and London solutions analogous in constitution; but differing in one containing the carbonate, the other the bicarbonate of soda. In the London preparation, half the soda is bicarbonated; in the U. S. solution, from a half to a third is monocarbonated, according to the quality of the chlorinated lime used. The Dublin may be supposed to be the same as the U. S. preparation, with the exception that, instead of having an excess of carbonate of soda, it contains an excess of undecomposed chlorinated lime. According to Millon's views, all these solutions contain *oxychloride of sodium*, $Na_2 \left\{ \begin{matrix} O_2 \\ Cl \end{matrix} \right.$, or, which is the same thing, chloride of soda, containing two eqs. of soda to one of chlorine ($2NaO,Cl$); thus making the compound assimilate in constitution to the sesquioxide of sodium (Na_2O_3). On Millon's supposition, two eqs. of carbonate of soda would be necessary to decompose one of chlorinated lime, with the result of forming one eq. of chlorinated soda, one of carbonate of lime, and one of free carbonic acid. Mr. B. Kavanagh, of Dublin, finds that a solution of alum has its alumina precipitated upon being added to the London chlorinated soda liquid, without effervescence of carbonic acid, but with the evolution of chlorine on the application of heat. Hence he infers that the soda, not combined with carbonic acid in the preparation, is united with chlorine and not with hypochlorous acid, and, accordingly, conceives that he has proved the correctness of Millon's views. Upon the whole, analyses are wanting before we can determine the true constitution of the officinal solutions of chlorinated soda. The London solution, though made on Labarraque's plan, is considerably stronger than his preparation; for the London College dissolves the carbonate in about three times its weight of water, before transmitting the chlorine; whereas Labarraque dissolved it in four times its weight.

Medical Properties and Uses. Solution of chlorinated soda is stimulant, antiseptic, and resolvent. Internally it has been employed in diseases termed *putrid*

or *malignant*, as typhus fever, scarlatina maligna, &c. The conditions which indicate the propriety of its use are great prostration of strength, fetid evacuations, and dry and furred tongue. Under these circumstances it promotes urine, creates a moisture on the skin, and improves the secretions and evacuations. It has also been given in dysentery accompanied with peculiarly fetid stools, in dyspepsia attended with putrid eructations, and in glandular enlargements and chronic mucous discharges. Other diseases in which it has been recommended, are secondary syphilis, scrofula, bilious disorders, and chronic diseases of the skin. M. Chailly speaks in praise of it in suppressed or deficient menstruation. In asphyxia from sulphuretted hydrogen it forms, like chlorinated lime, an efficacious antidote. The dose is from thirty drops to a teaspoonful, given in a cupful of water or mild aqueous liquid, and repeated every two or three hours.

As a local remedy it is found useful in all affections attended with fetor, such as gangrenous, cancerous, scrofulous, and syphilitic ulcers, ulceration of the gums, carbuncle, ozæna, mortification, putrid sorethroat, &c. In these cases it is applied as a gargle, wash, ingredient of poultices, or imbibed by lint. In the sloughing of the fauces attendant upon severe cases of scarlatina, Dr. Jackson, late of Northumberland, found it efficacious, used as a gargle, or injected into the throat. In the sore mouth from ptyalism, it forms a good mouth-wash, when diluted with eight parts or more of water. In fetid discharges from the vagina, uterus, and bladder, it has been employed with advantage as an injection, diluted with from fifteen to thirty parts of water for the vagina and uterus, and with sixty parts when the object is to wash out the bladder by means of a double cannula. The solution of chlorinated soda has also been applied successfully to burns, and to cutaneous eruptions, particularly psoriasis, tinea capitis, scabies, and obstinate herpetic affections. In these cases it is diluted with from ten to thirty parts of water, the strength varying according to circumstances. For the cure of sore nipples, Dr. Chopin found nothing so successful as frequently repeated lotions with this solution.

Solution of chlorinated soda is a powerful disinfectant, better suited for disinfecting operations on a small scale than chlorinated lime. In the bed-chambers of the sick, especially with infectious diseases, it will be found highly useful, sprinkled on the floor or bed, and added to the vessels intended to receive the excretions.

SODÆ ET POTASSÆ TARTRAS. *U. S.*, *Dub.* Sodæ Potassio-tartras. *Lond.* Potassæ et Sodæ Tartras. *Ed.* *Tartrate of Potassa and Soda.* *Tartarized Soda.* *Rochelle Salt.*

"Take of Carbonate of Soda *a pound;* Bitartrate of Potassa [cream of tartar], in powder, *sixteen ounces;* Boiling Water *five pints.* Dissolve the Carbonate of Soda in the Water, and gradually add the Bitartrate of Potassa. Filter the solution, and evaporate until a pellicle forms; then set it aside to crystallize. Pour off the liquor, and dry the crystals on bibulous paper. Lastly, again evaporate the liquor, that it may furnish more crystals." *U. S.*

The *Edinburgh* and *Dublin* processes correspond with the above. The *London College* has transferred this salt to the list of Materia Medica.

This is a double salt, consisting of tartrate of potassa combined with tartrate of soda. The theory of its formation is exceedingly simple, being merely the saturation of the excess of acid in the bitartrate of potassa by carbonate of soda, the carbonic acid of which is extricated with effervescence. The proper quantities of the materials for mutual saturation are 143·3 parts of carbonate and 188·2 of bitartrate, or one eq. of each. This gives the ratio of 3 to 3·95. The proportion adopted in the U. S., Edinburgh, and Dublin Pharmacopœias is as 3 to 4, which is very near the theoretical quantities. As the salts employed are

apt to vary in composition and purity, the carbonate from the presence of more or less water of crystallization, and the bitartrate from containing tartrate of lime, it is, perhaps, best in all cases, after indicating the nearest average proportion as a general guide, to present to the operator the alternative of using the cream of tartar to the point of exact saturation.

Properties. Tartrate of potassa and soda is in the form of colourless, transparent, slightly efflorescent crystals, often very large, and having the shape, when carefully prepared, of right prisms, with ten or twelve unequal sides. As ordinarily crystallized, they are generally in half prisms, as if split in the direction of their axis. The salt is of a saline and slightly bitter taste. It dissolves in five times its weight of cold water, and in much less boiling water. Any undissolved residue is impurity, probably tartrate of lime or bitartrate of potassa, or both. Its solution is neutral to test paper, and yields no precipitate with chloride of barium or a dilute solution of nitrate of silver. The non-action of these tests shows the absence of sulphates and chlorides. When the salt is exposed to a strong heat, the tartaric acid is destroyed, and a mixture of the carbonates of potassa and soda is left. It sometimes contains tartrate of lime, which may be removed by solution and crystallization; but, when the crystals are large and well defined, it may be assumed to be pure. It is incompatible with most acids, and with all acidulous salts except bitartrate of potassa. It is also decomposed by the acetate and subacetate of lead, by the soluble salts of lime, and by those of baryta, unless the solution of the tartrate be considerably diluted. The way in which acids act in decomposing it, is by combining with the soda, and throwing down bitartrate of potassa as a crystalline precipitate. This double salt was discovered by Seignette, an apothecary of Rochelle; and hence it is frequently called *Seignette's salt*, or *Rochelle salt.*

Composition. Tartrate of potassa and soda consists of two eqs. of tartaric acid 132, one of potassa 47·2, one of soda 31·3, and eight of water 72=282·5; or, considered as a double salt, of one eq. of tartrate of potassa 113·2, and one of tartrate of soda 97·3, with the same quantity of water.

Medical Properties and Uses. This salt is a mild, cooling purgative, well suited to delicate and irritable stomachs, being among the least unpalatable of the neutral salts. As it is not incompatible with tartar emetic, it may be associated with that salt in solution. It is an ingredient in the effervescing aperient called Seidlitz powders. (See *page* 54.) The dose as a purge is from half an ounce to an ounce. Given in small and repeated doses it does not purge, but is absorbed, and renders the urine alkaline. (Millon and Laveran, *Journ. de Pharm.*, 3e *sér.*, vi. 222.)

Tartrate of potassa and magnesia, formed by saturating cream of tartar with carbonate of magnesia, has been proposed by M. Maillier as a safe and pleasant purgative. (*Journ. de Pharm.*, xiii. 252.) B.

SODÆ MURIAS PURUM. *Ed.* *Pure Muriate of Soda.* *Pure Chloride of Sodium.*

"Take *any convenient quantity* of Muriate of Soda; dissolve it in boiling water; filter the solution, and boil it down over the fire, skimming off the crystals which form. Wash the crystals quickly with cold water, and dry them." *Ed.*

This formula of the Edinburgh College is unnecessary. If commercial samples of chloride of sodium cannot be found pure enough to form muriatic acid, the salt may be purified as a preparatory step to the process for obtaining that acid; as is ordered by the College in the formula for *Acidum Muriaticum Purum*, where the directions for purifying the salt are unnecessarily repeated, after the admission of a distinct formula for that purpose. Pure muriate of soda is ordered by the College, with needless refinement, as an ingredient in the compound saline powder.

Off. Prep. Pulvis Salinus Compositus. B.

SODÆ PHOSPHAS. *U. S., Lond., Ed., Dub. Phosphate of Soda. Tribasic Phosphate of Soda.*

"Take of Bone, burnt to whiteness and powdered, *ten pounds;* Sulphuric Acid *six pounds;* Carbonate of Soda *a sufficient quantity.* Mix the powdered Bone with the Sulphuric Acid in an earthen vessel; then add a gallon of water, and stir them well together. Digest for three days, occasionally adding a little water to replace that which is lost by evaporation, and frequently stirring the mixture. At the expiration of this time, pour in a gallon of boiling water, and strain through linen, gradually adding more boiling water until the liquid passes nearly tasteless. Set by the strained liquor that the dregs may subside, from which pour off the clear solution, and boil it down to a gallon. To this solution, poured off from the dregs and heated in an iron vessel, add by degrees the Carbonate of Soda, previously dissolved in hot water, until effervescence ceases, and the phosphoric acid is completely neutralized; then filter the liquor, and set it aside to crystallize. Having removed the crystals, add, if necessary, a small quantity of Carbonate of Soda to the liquor, so as to render it slightly alkaline; then alternately evaporate and crystallize, so long as crystals are produced. Lastly, preserve the crystals in a well stopped bottle." *U. S.*

The *Edinburgh College* takes the same materials and in the same proportion, and proceeds substantially as above. The two pints and four fluidounces (Imperial measure) of sulphuric acid ordered by the College weigh six pounds. The *Dublin* takes *ten avoirdupois pounds* of calcined bone, *fifty-six Imperial fluidounces* (six and a half avoird. pounds nearly) of acid, *four and a half Imperial gallons* or *sufficient* distilled water, and *twelve avoird. pounds* or *sufficient* crystallized carbonate of soda, and makes the salt in the usual way.

The *London College* places this salt in the list of Materia Medica.

The incombustible part of bones is obtained by burning them to whiteness, and consists of a peculiar phosphate of lime, called bone-phosphate, associated with some carbonate of lime, &c. (See *Os.*) When this is mixed with sulphuric acid, the carbonate of lime is entirely decomposed, giving rise to effervescence. The phosphate of lime undergoes partial decomposition; the greater part of the lime, being detached, precipitates as sulphate of lime, while the phosphoric acid, set free, combines with the undecomposed portion of the phosphate, and remains in solution as a superphosphate of lime, holding dissolved a small portion of the sulphate of lime. In order to separate the superphosphate from the precipitated mass of sulphate of lime, boiling water is added to the mixture, the whole is strained, and the sulphate washed as long as superphosphate is removed, which is known by the water passing through in an acid state. The different liquids which have passed the strainer, consisting of the solution of superphosphate of lime, are mixed and allowed to stand, and by cooling a portion of sulphate of lime is deposited, which is got rid of by decantation. The bulk of the liquid is now reduced by evaporation, and, in consequence of the diminution of the water, a fresh portion of sulphate of lime is deposited, which is separated by subsidence and decantation as before. The superphosphate of lime solution being heated, is now saturated by means of a hot solution of carbonate of soda. The carbonic acid is extricated with effervescence, and the alkali, combining with the *excess* of acid of the superphosphate, generates that variety of phosphate of soda, called the tribasic phosphate; while the superphosphate of lime, by the loss of its excess of acid, becomes the neutral phosphate, and precipitates. It is recommended by the editor of the Dublin Hospital Gazette to have both solutions *boiling hot*, in order to insure the full extrication of the carbonic acid, and the complete precipitation of the phosphate of lime; and this plan is adopted in the Dublin formula. The phosphate of lime is separated by a new filtration;

and the filtered liquor, consisting of the solution of phosphate of soda, is evaporated so as to crystallize.

In the U. S. and Edinburgh processes, the calcined bone is to the acid as 10 to 6; in the Dublin process as 10 to 6½ nearly. The proportion recommended by Berzelius is as 10 to 6·66. The acid, in the officinal processes, is added to the calcined bone in the concentrated state, and afterwards diluted with more or less water. In the process given by Berzelius it is first diluted with twelve times its weight of water. All the writers state that phosphate of soda crystallizes more readily by allowing its solution to be slightly alkaline; and a remarkable fact is that a neutral solution, when it crystallizes, leaves a supernatant liquid which is slightly acid and uncrystallizable. Hence it is necessary, after getting each successive crop of crystals, to render the mother water neutral or slightly alkaline, before it will furnish an additional quantity.

M. Funcke, a German chemist, has given the following cheap and expeditious method for obtaining phosphate of soda. Add to the powdered calcined bone, diffused in water, sufficient dilute sulphuric acid to decompose all the carbonate of lime which it contains. As soon as the effervescence has ceased, the matter is acted on with nitric acid, which dissolves the phosphate of lime, and leaves the sulphate. The nitric solution of the phosphate is then treated with sulphate of soda, equal in quantity to the bone employed; and, after the reaction is completed, the nitric acid is recovered by distillation. In consequence of a double decomposition, sulphate of lime and phosphate of soda are formed; and the latter is separated from the former by the action of water, and crystallized in the usual manner.

Properties, &c. The medicinal phosphate of soda is in large colourless crystals, which are transparent at first, but speedily effloresce and become opaque when exposed to the air, and which have the shape of oblique rhombic prisms. It possesses a pure saline taste, resembling that of common salt. With tests it displays a slight alkaline reaction. It dissolves in four parts of cold, and in two of boiling water, but is insoluble in alcohol. Before the blowpipe it first undergoes the aqueous fusion, and afterwards, at a red heat, melts into a globule of limpid glass, which becomes opaque on cooling. It is not liable to any adulterations, but sometimes contains carbonate of soda, from this salt being added in excess; in which case it will effervesce with acids. If it contain sulphate of soda, or any other soluble sulphate, the precipitate caused by chloride of barium will be a mixture of sulphate and phosphate of baryta, and will not be totally soluble in nitric acid. Chloride of barium will detect carbonate of soda also, by producing a precipitate (carbonate of baryta), soluble with effervescence in nitric acid. If a chloride be present, the *yellow* precipitate caused by nitrate of silver will be a mixed one of chloride and phosphate of silver, not entirely soluble in the same acid. It is incompatible with soluble salts of lime, with which it gives a precipitate of phosphate of lime, and with neutral metallic solutions. This salt is found in several of the animal secretions, particularly the urine.

The medicinal phosphate of soda is the tribasic phosphate, consisting, when crystallized, of one eq. of phosphoric acid 72, two of soda 62·6, one of basic water 9, and twenty-four of water of crystallization 216=359·6. Its formula is, therefore, $2NaO,HO,PO_5+24HO$. When gently heated it loses its water of crystallization; and at a red heat its basic water is driven off, and the salt is converted into *pyrophosphate of soda*, or the *bibasic phosphate*, which has the formula $2NaO,PO_5$, and is characterized by giving a *white* precipitate with nitrate of silver. When the tribasic salt is thus dried and ignited, it loses 62·3 per cent. of water. (*Lond. Pharm.*)

Medical Properties and Uses. This salt was introduced into practice about the year 1800, by Dr. Pearson, of London. It is a mild purgative, and, from

its pure saline taste, is well adapted to the cases of children, and of persons of delicate stomach. The dose is from one to two ounces, and is best given in gruel or weak broth, to which it communicates a taste, as if seasoned with common salt.

SODÆ VALERIANAS. *Dub. Valerianate of Soda.*

"Take of Bichromate of Potash, reduced to powder, *nine ounces* [avoirdupois]; Fusel Oil *four fluidounces* [Imp. meas.]; Oil of Vitriol of Commerce *six fluidounces and a half* [Imp. meas.]; Water *half a gallon* [Imp. meas.]; Solution of Caustic Soda *one pint* [Imp. meas.], or *as much as is sufficient.* Dilute the Oil of Vitriol with ten [fluid] ounces, and dissolve with the aid of heat the Bichromate of Potash in the remainder of the Water. When both solutions have cooled to nearly the temperature of the atmosphere, place them in a matrass, and, having added the Fusel Oil, mix well by repeated shaking, until the temperature of the mixture, which first rises to about 150°, has fallen to 80° or 90°. The matrass having been now connected with a condenser, heat is to be applied, so as to distil over about half a gallon of liquid. Let this, when exactly saturated with the Solution of Caustic Soda, be separated from a little oil that floats on its surface, and evaporated down until, the escape of aqueous vapour having entirely ceased, the residual salt is partially liquefied. The heat should now be withdrawn, and when the Valerianate of Soda has concreted, it is, while still warm, to be divided into fragments, and preserved in a well stopped bottle." *Dub.*

This is a new officinal of the Dublin Pharmacopœia of 1850. The process for making it consists essentially of two steps; first, the artificial formation of valerianic acid, and, secondly, the saturation of this acid with caustic soda. By distilling fusel oil with a mixture of sulphuric acid and bichromate of potassa, valerianic acid is formed, and passes over with water. The change is effected by the oxidizing agency of the chromic acid of the bichromate; for when fusel oil loses two eqs. of hydrogen by oxidation into water, and gains two of oxygen, it is converted into valerianic acid. Thus, $C_{10}H_{11}O + HO$ and $4O = C_{10}H_9O_3 + HO$ and $2HO$. (See *Potassæ Bichromas* and *Alcohol Amylicum.*) The distillate, by being exactly saturated with the solution of caustic soda, is converted into a solution of valerianate of soda, which, by the application of heat until the water is driven off, and the residual matter is partially liquefied, furnishes, on cooling, the concrete salt. The small portion of oil that floats on the surface of the solution of valerianate of soda is valerianate of amylic ether ($C_{10}H_{11}O$, $C_{10}H_9O_3$).

Properties, &c. Valerianate of soda is a deliquescent very soluble salt, in snow-white masses, having the odour of valerian, and a taste at first styptic, and afterwards sweetish. When heated to 285°, it fuses without loss of acid, and, upon cooling, concretes into a white solid. The salt, as ordered by the Dublin College, is in the form produced by partial fusion. It consists of one eq. of valerianic acid and one of soda ($NaO,C_{10}H_9O_3$). It has no medical applications; having been introduced into the Dublin officinal catalogue for the sole purpose of forming, by double decomposition, the valerianates of iron, quinia, and zinc.

SPIRITUS. *U.S., Lond.*
Spirits. Ed., Dub.

Spirits, as the term is here used, are alcoholic solutions of volatile principles, formerly procured by distillation, but now frequently prepared by simply dissolving the volatile principle in alcohol or diluted alcohol. The distilled spirits are prepared chiefly from aromatic vegetable substances, the essential oils of

which rise with the vapour of alcohol, and condense with it in the receiver. Some of the oils, however, will not rise at the temperature of boiling alcohol, but may be distilled with water. In this case it is necessary to employ proof spirit or diluted alcohol, with the water of which the oil comes over in the latter part of the process. As the proof spirit of the shops is often impregnated with foreign matters, which give it an unpleasant flavour, it is better to use alcohol which has been carefully rectified, and to dilute it with the due proportion of water, as directed by the U. S. Pharmacopœia. In preparing the spirits, care should be taken to avoid the colour and empyreumatic flavour arising from the decomposition of the vegetable matter by heat. Sufficient water must, therefore, be added to cover the vegetable matter after the alcohol shall have been distilled; and, as a general rule, the heat should be applied by means of a water-bath, or of steam. The aromatic should be macerated for some days with the alcohol, before being submitted to distillation; as the oil, being thus dissolved, rises more readily with the spirituous vapour than when confined in the vegetable tissue. It is necessary, during the process, frequently to renew the water in the refrigeratory; as otherwise much of the vapour will escape condensation. A good apparatus for the purpose is described and figured in *page* 793.

The aromatic spirits are used chiefly to impart a pleasant odour and taste to mixtures, and to correct the nauseating and griping effects of other medicines. They serve also as carminatives in flatulent colic, and agreeable stimulants in debility of stomach; but their frequent use may lead to the formation of intemperate habits, and should, therefore, be avoided. W.

SPIRITUS ANISI. *Lond.* *Spirit of Aniseed.*

"Take of Oil of Anise *three fluidrachms;* Proof Spirit *a gallon* [Imperial measure]. Dissolve." *Lond.*

The dose of this preparation, as a stomachic and carminative, is one or two fluidrachms. W.

SPIRITUS ARMORACIÆ COMPOSITUS. *Lond.* *Compound Spirit of Horse-radish.*

"Take of Horse-radish [root], sliced, Dried Orange Peel, each, *twenty ounces;* Nutmeg, bruised, *five drachms;* Proof Spirit *a gallon* [Imperial measure]; Water *two pints* [Imp. meas.]. Mix them; then, with a slow fire, distil a gallon." *Lond.*

This may be used advantageously as an addition to diuretic remedies, in dropsy attended with debility, especially in the cases of drunkards. The dose is from one to four fluidrachms.

Off. Prep. Infusum Armoraciæ Compositum. W.

SPIRITUS CARUI. *Lond., Ed.* *Spirit of Caraway.*

"Take of Oil of Caraway *two fluidrachms;* Proof Spirit *a gallon* [Imperial measure]. Dissolve." *Lond.*

"Take of Caraway, bruised, *half a pound;* Proof Spirit *seven pints* [Imperial measure]. Macerate for two days in a covered vessel; add a pint and a half [Imp. meas.] of water; and distil off seven pints." *Ed.*

The dose as a carminative is one or two fluidrachms. W.

SPIRITUS CASSIÆ. *Ed.* *Spirit of Cassia.*

"Take of Cassia in coarse powder, *one pound.* Proceed as for the Spirit of Caraway." *Ed.* (See *Spiritus Carui.*)

This is essentially the same as the spirit of cinnamon. W.

SPIRITUS CINNAMOMI. *Lond., Ed.* *Spirit of Cinnamon.*

"Take of Oil of Cinnamon *two fluidrachms;* Proof Spirit, *a gallon* [Imperial measure]. Dissolve." *Lond.*

The *Edinburgh College* prepares it from *a pound* of cinnamon, in coarse powder, in the same manner as spirit of caraway. (See *Spiritus Carui.*)

The spirit of cinnamon is an agreeable aromatic cordial, and may be given in debility of the stomach in the dose of one or two fluidrachms.

Off. Prep. Infusum Digitalis; Infusum Rhei; Mistura Cretæ. W.

SPIRITUS JUNIPERI COMPOSITUS. *U. S.*, *Lond.*, *Ed.*, *Dub.* *Compound Spirit of Juniper.*

"Take of Oil of Juniper *a fluidrachm and a half;* Oil of Caraway, Oil of Fennel, each, *ten minims;* Diluted Alcohol *a gallon.* Dissolve the Oils in the Diluted Alcohol." *U. S.*

"Take of Oil of Juniper *a fluidrachm and a half;* Oil of Caraway, Oil of Fennel, each, *twelve minims;* Proof Spirit *a gallon* [Imperial measure]. Dissolve." *Lond.*

"Take of Juniper Berries, bruised, *a pound;* Fennel [seed], bruised, and Caraway, bruised, of each, *an ounce and a half;* Proof Spirit *seven pints* [Imp. meas.]; Water *two pints.* Macerate the fruits in the Spirit for two days, add the Water, and distil off seven pints." *Ed.*

"Take of Juniper Berries, bruised, *eight ounces* [avoirdupois]; Caraway Seed, bruised, Fennel Seed, bruised, of each, *one ounce* [avoird.]; Proof Spirit *half a gallon* [Imp. meas.]. Macerate the Berries and the Seeds in the Spirit for twenty-four hours; then add the Water, and with a slow fire distil off half a gallon." *Dub.*

This spirit is a useful addition to diuretic infusions and mixtures in debilitated cases of dropsy. The dose is from two to four fluidrachms.

Off. Prep. Mistura Creasoti. W.

SPIRITUS LAVANDULÆ. *U. S.*, *Ed.* *Spirit of Lavender.*

"Take of Fresh Lavender [flowers] *two pounds;* Alcohol *a gallon;* Water *two pints.* Mix them, and with a slow fire distil a gallon." *U. S.*

The *Edinburgh College* takes *two pounds and a half* of the fresh flowers, and *a gallon* [Imperial measure] of rectified spirit; mixes them, and with the heat of a vapour-bath distils seven pints.

Mr. Brande asserts that the dried flowers produce as fragrant a spirit as the fresh. Spirit of lavender is used chiefly as a perfume, and as an ingredient in other preparations. The perfume usually sold under the name of *lavender water* is not a distilled spirit, but an alcoholic solution of the oil, with the addition of other odorous substances. The following is given by Mr. Brande as one of the most approved recipes for preparing it. "Take of rectified spirit of wine five gallons, essential oil of lavender twenty ounces, essential oil of bergamot five ounces, *essence of ambergris* [made by digesting one drachm of ambergris and eight grains of musk in half a pint of alcohol] half an ounce. Mix."

Off. Prep. Mistura Ferri Composita; Spiritus Lavandulæ Comp. W.

SPIRITUS LAVANDULÆ COMPOSITUS. *U. S.*, *Ed.*, *Dub.* TINCTURA LAVANDULÆ COMPOSITA. *Lond.* *Compound Spirit of Lavender.*

"Take of Spirit of Lavender *three pints;* Spirit of Rosemary *a pint;* Cinnamon, bruised, *an ounce;* Cloves, bruised, *two drachms;* Nutmeg, bruised, *half an ounce;* Red Saunders, rasped, *three drachms.* Macerate for fourteen days, and filter through paper." *U. S.*

The *London College* takes *a fluidrachm and a half* of oil of lavender, *ten minims* of oil of rosemary, *two drachms and a half* of bruised cinnamon, *the same quantity* of bruised nutmeg, *five drachms* of sliced red saunders, and *two pints* [Imp. meas.] of rectified spirit; macerates the solids in the spirit for seven days; then expresses, filters, and dissolves the oils. The *Edinburgh College*

takes *two pints* [Imp. meas.] of spirit of lavender, *twelve fluidounces* of spirit of rosemary, *an ounce* of cinnamon in coarse powder, *two drachms* of bruised cloves, *half an ounce* of bruised nutmeg, and *three drachms* of red saunders; macerates for seven days, and then strains the liquor through calico.

"Take of Oil of Lavender *three fluidrachms;* Oil of Rosemary *one fluidrachm;* Cinnamon, bruised, *one ounce* [avoirdupois]; Nutmeg, bruised, *half an ounce* [avoird.]; Cloves, bruised, Cochineal in powder, each, *two drachms* [Dub. weight]; Rectified Spirit *two pints* [Imp. meas.]. Macerate for fourteen days, strain, express, and filter." *Dub.*

Many druggists prepare this spirit with a spirit of lavender, made by dissolving the oil of lavender in alcohol in the proportion of a fluidounce to a gallon. Mr. Coggeshall, of New York, states that it is seldom made according to the U. S. formula, in consequence of the difficulty of procuring the distilled spirit of lavender, and that the oil dissolved in spirit yields an inferior preparation. He proposes the following formula, which he has employed with entire satisfaction. "Take of Lavender flowers *twelve ounces;* Rosemary leaves, Cinnamon, bruised, each, *four ounces and a half;* Nutmegs, bruised, Cloves, bruised, each, *six drachms;* Coriander, bruised, Red Saunders, each, *three ounces;* powdered Turmeric *one drachm;* Alcohol *six pints,* and Water *five pints and a quarter.* Mix, digest for fourteen days, and filter." (*N. Y. Journ. of Pharm.*, i. 99.)

When properly made, this is a delightful compound of spices. It is much employed as an adjuvant and corrigent of other medicines, and as a remedy for gastric uneasiness, nausea, flatulence and general languor or faintness. The dose is from thirty drops to a fluidrachm, and is most conveniently administered on a lump of sugar.

Off. Prep. Aqua Lauro-cerasi; Liquor Potassæ Arsenitis. W.

SPIRITUS MENTHÆ PIPERITÆ. *Lond.* SPIRITUS MENTHÆ. *Ed.* *Spirit of Peppermint.*

"Take of Oil of Peppermint *three fluidrachms;* Proof Spirit *a gallon* [Imperial measure]. Dissolve." *Lond.*

The *Edinburgh College* prepares this spirit from *a pound and a half* of fresh peppermint, in the same manner as spirit of caraway. (See *Spiritus Carui.*)

The distilled spirit of peppermint has no advantage over a simple solution of the oil in alcohol; and the London College has adopted this mode of preparing it. The U. S. Pharmacopœia has a preparation consisting of the oil dissolved in alcohol, such as has long been used under the name of *essence of peppermint.* But this is much stronger than the Spirits, and has been placed among the tinctures in our officinal code. (See *Tinctura Olei Menthæ Piperitæ.*) W.

SPIRITUS MENTHÆ VIRIDIS. *Lond.* *Spirit of Spearmint.*

This is prepared by the *London College* from the oil of spearmint, in the manner directed for the preparation of the spirit of peppermint. (See *Spiritus Menthæ Piperitæ.*)

The two spirits are used for the same purposes, in the dose of from thirty drops to a fluidrachm. They are employed chiefly as carminatives. W.

SPIRITUS MYRISTICÆ. *U. S., Lond., Ed.* *Spirit of Nutmeg.*

"Take of Nutmeg, bruised, *two ounces;* Diluted Alcohol *a gallon;* Water *a pint.* Mix them, and with a slow fire distil a gallon." *U. S.*

The *London* and *Edinburgh Colleges* take *two ounces and a half* of bruised nutmeg, *a gallon* [Imp. meas.] of proof spirit, and *a pint* [Imp. meas.] of water; mix them; and distil a gallon.

The spirit of nutmeg is used chiefly for its flavour, as an addition to other medicines. The dose is one or two fluidrachms.

Off. Prep. Mistura Ferri Composita. W.

SPIRITUS PIMENTÆ. *U. S., Lond., Ed. Spirit of Pimento.*

"Take of Oil of Pimento *two fluidrachms;* Diluted Alcohol *a gallon.* Dissolve the Oil in the Diluted Alcohol." *U. S.*

The *London College* prepares it as above, using an Imperial gallon of proof spirit; the *Edinburgh*, from *half a pound* of bruised pimento, in the same manner as spirit of caraway.

This preparation may be used for the general purposes of the aromatic spirits, in the dose of one or two fluidrachms. W.

SPIRITUS PULEGII. *Lond. Spirit of European Pennyroyal.*

"Take of Oil of Pennyroyal *three fluidrachms;* Proof Spirit *a gallon* [Imperial measure]. Dissolve." *Lond.*

This is never used in this country. W.

SPIRITUS ROSMARINI. *U. S., Lond., Ed. Spirit of Rosemary.*

"Take of Oil of Rosemary [by weight] *four drachms;* Alcohol *a gallon.* Dissolve the Oil in the Alcohol." *U. S.*

The *London College* dissolves *two drachms* of oil of rosemary in *a gallon* [Imperial measure] of rectified spirit. The *Edinburgh College* takes *two pounds and a half* of rosemary, and proceeds as for the spirit of lavender.

Spirit of rosemary is a grateful perfume, and is used chiefly as an ingredient in lotions and liniments.

Off. Prep. Linimentum Ammoniæ Compositum; Linimentum Saponis; Spiritus Lavandulæ Compositus. W.

SPONGIA.

Preparation of Sponge.

SPONGIA USTA. *U. S. Burnt Sponge.*

"Take of Sponge *a convenient quantity.* Cut it into pieces, and beat it, that any extraneous matters may be separated; then burn it in a close iron vessel until it becomes black and friable; lastly, rub it into very fine powder." *U. S.*

The sponge is decomposed, the volatile matters being driven off by the heat, and a black friable coal remaining. Preuss found that, of 1000 parts of sponge submitted to calcination, 343·848 were dissipated; and the residue consisted of 327·0 parts of carbon and insoluble matters, 112·08 of chloride of sodium, 16·43 of sulphate of lime, 21·422 of iodide of sodium, 7·57 of bromide of magnesium, 103·2 of carbonate of lime, 35·0 of phosphate of lime, 4·73 of magnesia, and 28·72 of protoxide of iron. (*Pharm. Cent. Blatt*, 1837, 169.) Herberger found in burnt sponge one per cent. of iodide of potassium, and 0·5 per cent. of bromide of potassium. (*Annal. der Pharm.*, xx. 204.) As the remediate value of burnt sponge depends chiefly upon the presence of iodine, it cannot be esteemed good unless it affords purple fumes when acted on by sulphuric acid assisted by heat. It is said that the preparation is most efficient as a remedy, when the sponge is kept on the fire no longer than is necessary to render it friable. The powder is then of a much lighter colour. Guibourt recommends that the sponge selected for burning should be unwashed, of a strong odour, firm, and compact, that it should be put into a roaster similar to that sometimes used for coffee, and heated over a moderate fire till it becomes of a blackish-brown colour, that it should then be removed, powdered, and enclosed in a well stopped glass bottle. It is best when recently prepared; as the iodine is dissipated by time, and the specimens, at first richest in this principle, contain little of it at the end of a year. (*Journ. de Chim. Méd.*, Dec. 1831.) According to Herberger, the fine and coarse sponges do not materially differ in the proportion of their organic constituents; so that the coarse may be selected for this operation.

Burnt sponge has been highly recommended in goitre, glandular swellings of a scrofulous character, and obstinate cutaneous eruptions. It is most conveniently administered mixed with syrup or honey, in the form of an electuary, with the addition of some aromatic, as powdered cinnamon. The dose is from one to three drachms. W.

STANNUM.

Preparation of Tin.

STANNI PULVIS. *U. S.*, *Ed.*, *Dub.* *Powder of Tin.*

"Take of Tin *a convenient quantity.* Melt it in an iron vessel over the fire, and, while it is cooling, stir it until it is reduced to a powder, which is to be passed through a sieve." *U. S.*

"Melt Tin in an iron vessel; pour it into an earthenware mortar, heated a little above the melting point of the metal; triturate briskly as the metal cools, ceasing as soon as a considerable proportion is pulverized; sift the product, and repeat the process with what remains in the sieve." *Ed.*

"Take of grain Tin *a convenient quantity.* Melt the Tin in a black lead crucible, and, while it is cooling, stir it with a rod of iron until it is reduced to powder. Let the finer particles be separated by means of a sieve, and when, after having been several times in succession shaken with distilled water, the decanted liquor appears quite clear, let the product be dried and preserved for use." *Dub.*

Tin, being a very fusible metal, is easily granulated by fusion, and subsequent agitation in the act of congealing. On a small scale, the process is most conveniently performed in a wooden box, the inside of which has been well rubbed with chalk. This should be afterwards washed away by water; and, as the granulated powder is of unequal fineness, the coarser particles must be separated by a sieve. For the properties of this metal and the tests of its purity, see *Stannum.*

Medical Properties and Uses. Powder of tin is used exclusively as an anthelmintic, and is supposed to act by its mechanical properties. It is considered particularly adapted to the expulsion of *Ascaris lumbricoides*, and is sometimes employed to expel the tapeworm. For internal exhibition it should be free from oxidation. The dose is half an ounce, mixed with molasses, given for several successive mornings, and then followed by a brisk cathartic. Dr. Alston was in the habit of administering larger doses for the expulsion of the tapeworm. He began by giving an ounce on an empty stomach, which was followed, for two successive days, by half an ounce each day, and finally by a brisk purge. B.

STRYCHNIA.

Preparations of Strychnia.

STRYCHNIA. *U. S.*, *Lond.*, *Ed.*, *Dub.* *Strychnia.*

"Take of Nux Vomica, rasped, *four pounds;* Lime, in powder, *six ounces;* Muriatic Acid *three fluidounces;* Alcohol, Diluted Sulphuric Acid, Solution of Ammonia, Purified Animal Charcoal, Water, each, *a sufficient quantity.* Digest the Nux Vomica in two gallons of Water, acidulated with a fluidounce of the Muriatic Acid, for twenty-four hours; then boil for two hours, and strain with expression through a strong linen bag. Boil the residuum twice successively in the same quantity of acidulated Water, each time straining as before. Mix the decoctions and evaporate to the consistence of thin syrup; then add the Lime previously mixed with a pint of Water, and boil for ten minutes, frequently

stirring. Pour the mixture into a double linen bag, and, having washed the precipitate well with water, press, dry, and powder it. Treat the powder repeatedly with boiling Alcohol, until deprived of its bitterness; mix the liquors; and distil off the Alcohol by means of a water-bath. Mix the residue with Water, and, having applied heat, drop in sufficient Diluted Sulphuric Acid to neutralize and dissolve the Strychnia; then add Purified Animal Charcoal, boil for a few minutes, filter, evaporate, and crystallize. Dissolve the crystals in Water, and add sufficient Solution of Ammonia to precipitate the Strychnia. Lastly, dry the precipitate on bibulous paper." *U. S.*

The *London College* has transferred strychnia to its Materia Medica list.

"Take of Nux Vomica *one pound;* Quicklime *one ounce and a half;* Rectified Spirit *a sufficiency.* Subject the Nux Vomica for two hours to the vapour of steam, chop or slice it, dry it thoroughly in the vapour-bath, or hot air-press, and immediately grind it in a coffee-mill. Macerate it for twelve hours in two pints [Imperial measure] of water, and boil it; strain through linen or calico, and squeeze the residuum; repeat the maceration and decoction twice with a pint and a half of water. Concentrate the decoctions to the consistence of thin syrup; add the Lime in the form of milk of lime; dry the precipitate in the vapour-bath; pulverize it, and boil it with successive portions of Rectified Spirit till the Spirit ceases to acquire a bitter taste. Distil off the Spirit till the residuum be sufficiently concentrated to crystallize on cooling. Purify the crystals by repeated crystallizations." *Ed.*

"Take of Nux Vomica, in powder, *one pound* [avoirdupois]; Water *one gallon and a half;* Oil of Vitriol of Commerce *half a fluidounce;* Slaked Lime *one ounce* [avoird.]; Rectified Spirit *one quart;* Dilute Sulphuric Acid, Solution of Ammonia, of each, *a sufficient quantity;* Prepared Animal Charcoal *half an ounce* [avoird.]. Macerate the Nux Vomica for twenty-four hours with half a gallon of the Water, acidulated with two [fluid]drachms of the Acid, and, having boiled for half an hour, decant. Boil the residuum with a second half gallon of the Water, acidulated with one [fluid]drachm of the acid; decant, and repeat this process with the remaining Water and Acid, the undissolved matter being finally submitted to strong expression. The decanted and expressed liquors having been passed through a filter, and then evaporated to the consistence of a syrup, let this be boiled with the Rectified Spirit for twenty minutes, the Lime being added in successive portions during the ebullition, until the solution becomes decidedly alkaline. Filter through paper, and, having drawn off by distillation the whole of the spirit, let the residuum be dissolved in the Dilute Sulphuric Acid, and to the resulting liquid, after having been cleared by filtration, add the Solution of Ammonia in slight excess, and let the precipitate which forms be collected upon a paper filter, dried, and then dissolved in a minimum of boiling rectified spirit. Into this solution introduce the Animal Charcoal, digest for twenty minutes, then filter, and allow the residual liquor to cool, when the strychnia will separate in crystals." *Dub.*

It should be recollected that the British Imperial measure is employed by the Edinburgh and Dublin Colleges throughout these processes.

In preparing strychnia, the first step is properly to comminute the nux vomica. This may be done by rasping the seeds, or, as directed in the Edinburgh Pharmacopœia, by first softening them by steam, then slicing, drying, and grinding them. The next object is to extract the strychnia. For this purpose water is employed, acidulated in the U. S. process with muriatic acid, in the Dublin with sulphuric acid, in the Edinburgh without addition. In the last, the native igasurate of strychnia is taken up; in the first the muriate, which is a very soluble salt, and in the second the sulphate. In the U. S. and Edinburgh processes, after a concentration of the infusion, the salt of strychnia is

decomposed by lime, which precipitates the strychnia along with the excess of lime employed and impurities. The strychnia is extracted from the precipitate by boiling alcohol, and may be obtained in crystals by the concentration of the solution. But in this state it is much coloured and impure. The Edinburgh College contents itself with directing it to be purified by repeated solution in alcohol and crystallization. In the U. S. process, the impure strychnia is converted into a sulphate by the addition of sulphuric acid, and precipitated again by ammonia; being, while in the state of the sulphate, decolorized by means of animal charcoal. The Dublin College adds the rectified spirit before adding the lime, so that the separated strychnia is held in solution; then, having got rid of the insoluble impurities by filtration, it distils off the spirit, and proceeds to purify the residue by dissolving it in sulphuric acid, precipitating with ammonia, redissolving the precipitated strychnia in boiling alcohol, decolorizing by animal charcoal, and crystallizing by refrigeration. Throughout the process, the brucia contained in the nux vomica attends the strychnia, and is only left behind in the mother liquors, when the latter alkali crystallizes from the alcoholic solution upon cooling; brucia being much more soluble than strychnia in cold alcohol. It would, therefore, be better to conclude the U. S. process by one or more solutions and crystallizations in alcohol, as directed by the Edinburgh and Dublin Colleges. To free the strychnia entirely from brucia requires repeated crystallizations, and a little of the latter principle is consequently almost always retained; but the impurity is not injurious, as the effects of the two alkalies upon the system are very similar. The bean of St. Ignatius yields strychnia more easily and more largely than nux vomica, but is less plentiful.*

If thought desirable, brucia may be in great measure separated from the strychnia of the shops, by dissolving the latter in very dilute nitric acid, filtering, and concentrating to the point of crystallization. The nitrate of brucia crystallizes in short, thick, dense prisms, grouped together; the nitrate of strychnia in radiated tufts of long, light, capillary needles. By gentle agitation with water, the latter salt is suspended and may be poured off, leaving the former. The alkalies may be obtained by dissolving the salts separately in water, and precipitating with ammonia. (*Christison.*)

As usually kept in the shops, strychnia is a grayish-white powder. When rapidly crystallized from its alcoholic solution, it has the form of a white, granular powder; when slowly crystallized, that of elongated octohedra, or quadrilateral prisms with quadrilateral terminations. It is permanent in the air, inodorous, but excessively bitter, with a metallic after taste. So intense is its bitterness, that one part of it is said to communicate a sensible taste to 600,000 parts of water. It melts like a resin, but is not volatile, being decomposed at a comparatively low temperature, and entirely dissipated at a red heat. It is soluble in 6667 parts of water at 50°, and about 2000 at the boiling point. Boiling officinal alcohol dissolves it without difficulty, and deposits it upon cool-

* M. J. F. Molyn proposes, previously to the extraction of strychnia, to subject nux vomica to fermentation, by which the saccharine and gummy matters of the seeds are decomposed, and lactic acid is formed, which decomposes the igasurate of strychnia and brucia, producing with these bases very soluble lactates. For the particulars of his process, see the *Am. Journ. of Pharm.* (xix. 99).

We are informed that none of the officinal processes are followed exactly by the large manufacturers in reference to the preliminary comminution of the nux vomica. The plan most approved is to macerate the whole seeds in dilute sulphuric acid, and to pass steam through them, under pressure, in a covered vat, lined with lead. The seeds softened in this way are then ground, and the pulp lixiviated or expressed. One advantage of the sulphuric acid, employed in this way, is thought to be the conversion of the bassorin, which impedes the process, into soluble dextrin. The liquors are precipitated with lime, and the process completed as officinally directed.—*Note to the tenth edition.*

ing. In absolute alcohol and in ether it is very sparingly soluble. The volatile oils dissolve it freely. It has an alkaline reaction on test paper, and forms salts with the acids. Nitric acid does not redden it if perfectly pure, but almost always reddens it as found in the shops, in consequence of the presence of brucia. M. Eugene Marchand proposes the following test, by which a very minute proportion of strychnia may be detected. If a little of the alkali be rubbed with a few drops of concentrated sulphuric acid containing one-hundredth of nitric acid, it will be dissolved without change of colour; but if the least quantity of peroxide of lead be added to the mixture, a magnificent blue colour will be instantly developed, which will pass rapidly into violet, then gradually to red, and ultimately become yellow. (*Journ. de Pharm.*, 3e *sér.*, iv. 200.) Professor Otto recommends as a test a minute quantity of solution of bichromate of potassa, which, added to the solution of strychnia in concentrated sulphuric acid, produces a splendid violet colour. (*Am. Journ. of Pharm.*, xix. 77.) A similar change of colour is produced, according to Dr. E. W. Davy, by substituting a strong solution of ferrocyanuret of potassium for that of bichromate of potassa. (*Ibid.*, xxv. 414.) Strychnia consists of nitrogen, carbon, hydrogen, and oxygen; but the proportion of its constituents is very differently given by different authors. Liebig states the composition to be $N_2C_{44}H_{23}O_4$. The salts of strychnia are for the most part soluble and crystallizable. Their solution is decomposed by the alkalies and their carbonates, and by tannic, but not by gallic acid; and is not affected by the salts of sesquioxide of iron. Strychnia is apt to contain impurities, of which the chief, besides brucia, are colouring matter, and lime or magnesia. The Edinburgh College gives the following test of its purity. "A solution of 10 grains in 4 fluidrachms of water by means of a fluidrachm of pyroligneous acid, when decomposed by one fluidounce of concentrated solution of carbonate of soda, yields on brisk agitation a coherent mass, weighing when dry 10 grains, and entirely soluble in solution of oxalic acid."

Medical Properties and Uses, &c. The effects of strychnia upon the system are identical in character with those of nux vomica, and it is employed for the same purposes as a medicine. (See *Nux Vomica*, page 491.) It operates in the same way by whatever avenue it may enter into the circulation; but is said to act most powerfully when injected into the veins, or applied to a fresh wound. The blood of an animal under its influence produces similar effects in another if transfused into its veins. In over-doses it is a most violent poison. Pelletier and Caventou killed a dog in half a minute with one-sixth of a grain of the pure alkali. One grain or even less might prove fatal in the human subject. A case, however, is recorded in which recovery took place after seven grains had been swallowed; but the medicine was probably impure. (See *Am. Journ. of Med. Sci.*, N. S., xxx. 562.) According to M. Duclos, the poisonous effects of strychnia upon animals subside under the application of negative electricity, while they are aggravated by the positive. (See *Am. Journ. of Pharm.*, xvi. 154.) M. Boudet has found that chlorine water alternated with tartar emetic, so as to produce vomiting, obviates these effects in dogs. (*Arch. Gén.*, Feb. 1853, p. 222.) Kermes mineral has been recommended by M. Thorel as an antidote, being thought by him to form with strychnia an insoluble sulphuret, at the same time aiding any other emetic which may be administered in its expulsion. In cases of poisoning with strychnia he recommends fifteen grains of kermes and one and a half grains of tartar emetic. MM. Bouchardat and Gobley state that, out of the body, the iodurettted iodide of potassium acts far more powerfully in producing an absolutely insoluble compound. (See *Am. Journ. of Pharm.*, xxiii. 84.) Chloroform by inhalation, has been found to correct the poisonous effects of strychnia, and the same is said of camphor taken internally. The indications

are to evacuate the stomach, and to relieve the spasms by opiates or other narcotics. Different persons are very differently susceptible to its action, and some are powerfully affected by the smallest doses. Besides, being more or less impure as kept in the shops, it cannot be relied on with certainty. Hence the necessity of great caution in prescribing it, and of carefully watching the patient during its use. The best plan is always to begin with very small doses, and gradually increase till its effects are observed. From one-twelfth to one-sixth of a grain internally, and from a quarter to half a grain externally, upon a blistered surface, may be employed at first; but, if the alkali is very pure, the dose may be still further reduced with propriety. It is most conveniently administered in the form of pill. It may be given also in the saline state, which is produced by dissolving it in water acidulated with sulphuric, muriatic, nitric, or acetic acid.

Off. Prep. Strychniæ Murias. W.

STRYCHNIÆ MURIAS. *Dub. Muriate of Strychnia.*

"Take of Strychnia *one ounce* [avoirdupois]; Dilute Muriatic Acid *one fluidounce* or *a sufficient quantity;* Distilled Water *two* [*fluid*]*ounces and a half.* Pour the Acid upon the Strychnia, and, adding the Water, apply heat until a perfect solution is obtained. Let this cool, and let the crystals which form be dried upon bibulous paper. By evaporating the residual liquid to one-third of its bulk, and then allowing it to cool, an additional quantity of the salt will be obtained." *Dub.*

The only advantage of this preparation is that, in consequence of its solubility in water, it affords the means of administering strychnia in the dissolved state; but this end, when desired, is so easily obtained by adding a few drops of an acid to strychnia, that it seems scarcely an object of sufficient importance to call for a distinct officinal preparation, especially as the intensely bitter taste of strychnia renders its administration in the form of pill generally preferable. Perhaps, in consequence of its solubility, muriate of strychnia may be preferable to the uncombined alkaloid for application to a blistered surface, with a view to its effects on the system. W.

SULPHUR.

Preparations of Sulphur.

SULPHUR PRÆCIPITATUM. *U. S., Lond.* Lac Sulphuris. *Precipitated Sulphur. Milk of Sulphur.*

"Take of Sulphur [sublimed] *a pound;* Lime *a pound and a half;* Water *two gallons;* Muriatic Acid *a sufficient quantity.* Slake the Lime with a small portion of the Water, and, having mixed it with the Sulphur, add the remainder of the Water, boil for two or three hours, occasionally adding water so as to preserve the measure, and filter. Dilute the filtered liquor with an equal bulk of water; then drop into it sufficient Muriatic Acid to precipitate the Sulphur. Lastly, wash the precipitate repeatedly with water till the washings are tasteless, and dry it." *U. S.*

This preparation, after having been dismissed from the London Pharmacopœia of 1836, has been restored in that of 1851, being placed in the list of Materia Medica with this definition: "Sulphur precipitated from sulphuret of calcium by hydrochloric acid."

In the U. S. process two eqs. of lime react with six of sulphur, so as to form two eqs. of bisulphuret of calcium, and one of hyposulphurous acid, which latter then unites with one eq. of lime to form hyposulphite of lime. On the addition of the muriatic acid, six eqs. of sulphur are precipitated (four from the two eqs. of bisulphuret of calcium and two from the one eq. of hyposulphurous acid),

and the calcium and oxygen unite with the muriatic acid, so as to form chloride of calcium and water. This acid is the most eligible precipitant for the sulphur; as it gives rise to chloride of calcium, which is a very soluble salt, and easily washed away. Sulphuric acid is wholly inadmissible; as it generates sulphate of lime, which, from its sparing solubility, becomes necessarily intermingled with the precipitated sulphur. According to Schweitzer, the best material from which to precipitate the sulphur is the sulphuret of potassium, formed by boiling sulphur with caustic potassa. Dr. Otto, of Brunswick, finds that sulphuret of potassium is apt to contain sulphuret of copper, and therefore prefers sulphuret of calcium. (*Pharm. Cent. Blatt*, Jan. 1845.)

Properties, &c. Precipitated sulphur is in friable lumps having a white colour, with a pale yellowish-green tint, and consisting of finely divided particles, slightly cohering together. Water boiled upon it should not redden litmus. When recently prepared, it is devoid of taste, but possesses a peculiar smell. When long exposed, in a moist state, to the air, it becomes strongly contaminated with sulphuric acid. (*Annalen der Pharm.*, xx. 151.) From its colour it was formerly called *lac sulphuris*, or *milk of sulphur*. It is insoluble in water, but dissolves in a boiling solution of caustic potassa, and in oil of turpentine by the aid of heat. When of a brilliant white colour, the presence of sulphate of lime may be suspected; in which case the preparation will not be wholly volatilized by heat. If pure it communicates a harsh feel when rubbed between the fingers, owing to the friction between the crystalline particles. (*Dr. Bridges.*) We have seen a sample of so-called precipitated sulphur, which consisted almost entirely of sulphate of lime. Precipitated sulphur differs from sublimed sulphur, in being in a state of more minute division, and in presenting, after fusion, a softer and less brittle mass. Its peculiarities are supposed to depend upon the presence of water, which, however, is found in too small a quantity to constitute a regular *hydrate*. According to Rose, its white colour is occasioned by the presence of a small proportion of bisulphuretted hydrogen. Soubeiran states that it always contains some sulphuretted hydrogen, which causes it to differ as a therapeutic agent from sublimed sulphur.

Medical Properties and Uses. Precipitated sulphur possesses similar medical properties to those of sublimed sulphur. Its state of extreme division renders it more readily suspended in liquids; but its liability to become acid by keeping is an objection to it. It is sometimes selected for forming ointments, which have the advantage to the eye of being of a lighter colour than when made with sublimed sulphur. The dose is from one to three drachms. (See *Sulphur.*) B.

SULPHURIS IODIDUM. *U. S.*, *Lond.* Sulphur Iodatum. *Dub.* *Iodide of Sulphur. Bisulphuret of Iodine.*

"Take of Iodine *four ounces;* Sulphur *an ounce.* Rub the Iodine and Sulphur together in a glass, porcelain, or marble mortar until they are thoroughly mixed. Put the mixture into a matrass, close the orifice loosely, and apply a gentle heat so as to darken the mass without melting it. When the colour has become uniformly dark throughout, increase the heat so as to melt the Iodide; then incline the matrass in different directions, in order to return into the mass any portions of Iodine which may have condensed on the inner surface of the vessel; lastly, allow the matrass to cool, break it, and put the Iodide into bottles, which are to be well stopped." *U. S.*

"Take of Sulphur *an ounce;* Iodine *four ounces.* Put the Sulphur into a glass vessel, and place the Iodine upon it. Hold the vessel in boiling water until they unite. Then break the vessel when the Iodide has become cold, and reduce this to pieces, which are to be kept in another vessel, well stopped." *Lond.*

The *Dublin College* takes *an ounce* of its pure iodine and *two drachms* of sublimed sulphur, and proceeds as in the U.S. formula.

The U.S. and Dublin process is that of the French Codex. The combination may be conveniently effected in a Florence flask. The London formula is peculiar in directing the application of the necessary heat by means of boiling water. This is an improvement on the usual mode of proceeding; as it effectually prevents the application of too high a heat. The iodine and sulphur are taken in the same proportion in all the formulæ.

Properties, &c. Iodide of sulphur has a grayish-black colour, and radiated crystalline appearance like that of sulphuret of antimony. Its smell resembles that of iodine, and it stains the cuticle in a similar manner. It is rapidly decomposed, when in the state of powder, upon the addition of several of the volatile oils, violet vapours of iodine being evolved, and the smell of sulphur perceived. (Dr. G. W. Patterson, *Am. Journ. of Pharm.*, July, 1852, p. 203.) It is entirely volatilized by heat, and by continued boiling with water is wholly decomposed, iodine escaping with the steam, and sulphur being left nearly pure. The proportion of sulphur thus obtained is about 20 per cent. (*Lond Pharm.*) This analysis shows that the compound is a bisulphuret. Iodide of sulphur has been used by Biett, Rayer, Lugol, and others as an external application in various skin diseases, such as tinea capitis, lupus, lepra, &c., applied in the form of ointment. (See *Unguentum Sulphuris Iodidi.*)

Off. Prep. Unguentum Sulphuris Iodidi. B.

SYRUPI.

Syrups.

Syrups are concentrated solutions of sugar in watery fluids, either with or without medicinal impregnation. When the solution is made with pure water, it is named *syrup* or *simple syrup*, when with water charged with one or more medicinal agents, it is called in general terms a *medicated syrup*, and receives its particular designation from the substance or substances added.

Medicated syrups are usually prepared by incorporating sugar with vegetable infusions, decoctions, expressed juices, fermented liquors, or simple aqueous solutions. When the active matter of the vegetable is not readily soluble in water, is associated with soluble matter which it is desirable to avoid, or is volatilized or decomposed by a heat of 212°, it is sometimes extracted by diluted alcohol, the spirituous ingredient of which is subsequently driven off. Medicated syrups are also occasionally prepared by adding a tincture to simple syrup, and evaporating the alcohol. Another and better mode of effecting the same object, when aromatic or other volatile substances are concerned, is to mix the tincture with sugar in coarse powder, expose the mixture to a very gentle heat or in the sun till the alcohol has evaporated, and then prepare the syrup from the impregnated sugar by dissolving it in the requisite proportion of water. Since the introduction into use of the process of percolation or filtration by displacement, it has been applied very advantageously to the preparation of various syrups, especially of those made from vegetables of which the active principle is injured or dissipated by decoction. But, unless the operator be at once skilful and very careful, there will be great danger of imperfectly extracting the active matters, and thus making a feeble preparation. One practical rule of importance, when the liquid obtained by percolation requires concentration, is to set aside the first portions of percolated liquor, which are usually strongly impregnated, and to subject only the subsequent weaker portions to evaporation. For the mode of properly conducting this process the reader is referred to *pages* 782 and 789.

The quality and quantity of the sugar employed are points of importance. Refined sugar should always be preferred, as it often saves the necessity of clarification, and makes a clearer and better flavoured syrup than the impure kinds. The U.S. Pharmacopœia simply directs sugar, but explains that it is the purified or refined sugar which is indicated by that term. In relation to the quantity of sugar, if in too small proportion, fermentation is apt to occur; if too abundant, crystallization. The proper proportion is about two parts to one of the liquid. A somewhat smaller quantity will answer where an acid, such as lemon juice or vinegar, is used.

As it is desirable, in many instances, that the active matters should be in as concentrated a state as possible in the syrup, it is often necessary to evaporate a large proportion of the watery fluid in which they are dissolved. This may be done either before the addition of the sugar or afterwards. In either case, care is requisite not to apply a heat too great or too long continued, lest the active principles should be injured. When these are very volatile or easily decomposed by heat, it is necessary to dispense with concentration altogether. Some substances which are volatilized or decomposed at the temperature of boiling water, remain fixed and unaltered at that which is necessary for the evaporation of alcohol. These, as before observed, may be dissolved in diluted alcohol, and the concentration effected by evaporating the spirituous part of the solvent. Independently of the injury which the medicinal ingredient of the syrup may sustain, the syrup itself is apt to become brown by a long-continued application of heat, even when the degree is not excessive. It is recommended, therefore, that syrups which admit of concentration should be boiled briskly over a lively fire, so as to accomplish the object as quickly as possible. It is important to be able to ascertain positively when they have attained the due consistence. An operator skilled in their preparation can judge with sufficient accuracy by various familiar signs; such as the slowness with which the parts of a drop of syrup coalesce, when previously separated by the edge of a blunt instrument; and the receding of the last portion of each drop, when the syrup, after being cooled, is poured out drop by drop. A pellicle forming upon the surface of the syrup when it cools, indicates that it has been too much boiled. But these signs are not to be relied on except by those who have acquired much experience. The easiest method of ascertaining the proper point of concentration is by the use of that variety of Baumé's hydrometer, called a *saccharometer;* an instrument almost indispensable to the apothecary. This should stand at 30° in boiling syrup (30½ in hot weather) and at 35° in the syrup when it is cool. Another very accurate though less ready method is to ascertain the sp. gr. by weighing a portion of the liquid. Syrup when boiling should have a sp. gr. of about 1·261; when cold, about 1·319. Thomson and Duncan are mistaken in giving the proper sp. gr. of cold syrup as 1·385. We found that of a specimen of simple syrup made with two pounds and a half of sugar to a pint of water, to be 1·326 at 68° F.; and this consistence is rather too great for practical convenience in cold weather. A third method of ascertaining the proper point of concentration is by the thermometer, which, in boiling syrup of the proper consistence, stands at 221° F. This indication is founded on the fact, that the boiling point of syrup rises in proportion to the increase of its density.

When carefully prepared with the best double refined sugar, syrups usually require no other clarification than to remove any scum which may rise to their surface upon standing, and to pour them off from any dregs which may subside. But as the sugar employed is seldom free from impurities, it may be best, as a general rule, to remove the scum as it rises during the heating process, and to strain them while hot through muslin or flannel. Should they at any time want

the due degree of clearness, they may be filtered through flannel, or, when not likely to be injured by the treatment, may be clarified by means of the white of eggs or animal charcoal, as mentioned under the head of *syrupus*. But the active principles of vegetables are so apt to be absorbed by the charcoal along with impurities, that this agent should be resorted to with great caution.

The medicated syrups are liable to undergo various alterations, according to their nature and mode of preparation. The acid syrups, when too much boiled, often let fall a copious white precipitate, which is said to be a saccharine matter analogous to the sugar of grapes, produced by the reaction of the acid upon the sugar. It has been shown that, even at ordinary temperatures, acids slowly convert common sugar into the sugar of grapes, which, being less soluble than the former, is gradually deposited in the form of crystalline grains. Syrups which contain too little sugar are apt to pass into the vinous fermentation, in consequence of the presence of matters which act as a ferment. Those which contain too much deposit a portion in the crystalline state; and the crystals, attracting the sugar remaining in solution, gradually weaken the syrup, and render it liable to the same change as when originally made with too little sugar. The want of a due proportion of saccharine matter frequently also gives rise to mouldiness, when air has access to the syrup. It is said that syrups, enclosed, while they are still hot, in bottles, are apt to ferment; because the watery vapour, rising to the surface and there condensing, diminishes the proportion of sugar, so as to produce a commencement of chemical action, which gradually extends through the whole mass; but if the bottles are well shaken this result is obviated; and the syrups will generally keep better when thus treated. When syrups undergo the vinous fermentation, they become covered at the surface with froth, produced by the disengagement of carbonic acid, and acquire a vinous odour from the presence of alcohol; while their consistence is diminished by the loss of a portion of the sugar, which has been converted into that liquid. When the quantity of alcohol has increased to a certain point, the fermentation ceases or goes on more slowly, owing to the preservative influence of that principle; and, as the active ingredient of the syrup has frequently undergone no material change, the preparation may often be recovered by boiling so as to drive off the alcohol and carbonic acid, and concentrate the liquid sufficiently. A syrup thus revived is less liable afterwards to undergo change, because the principles which acted as ferments have been diminished or consumed. It is obvious that syrups which depend for their virtues upon a volatile ingredient, or one readily changeable by heat, cannot be restored to their original condition.

At best, syrups are too apt to change, and various measures have been proposed for their preservation. According to Dr. Macculloch, the addition of a little sulphate of potassa or of chlorate of potassa which is tasteless, prevents their fermentation. M. Chereau has found sugar of milk effectual to the same end, in the instance of the syrup of poppies; and it may prove useful in others. The proportion which he employs is 32 parts of the sugar of milk to 1000 of the syrup. Mr. E. Durand has found that 1·3 per cent. of Hoffmann's anodyne (*Spiritus Ætheris Compositus*), added to syrups, has the property of completely arresting or preventing fermentation, probably through the agency chiefly of the oil of wine which it contains. (*Am. Journ. of Pharm.*, xiii. 185.) But the best plan is to make small quantities of syrups at a time, and to keep them, unless when wanted for immediate use, in bottles quite full and well stopped, which should be put in the cellar or other cool place.

The following general officinal directions are given in relation to syrups.

"Syrups whose density is not precisely determined by the process, should have the specific gravity 1·261 when boiling, and about 1·319 at ordinary temperatures." *U. S.*

"Let the syrups be preserved in vessels well closed, and in a place where the heat never exceeds 55°." *Lond.* It would be difficult to comply exactly with such a rule in this country. W.

SYRUPUS. *U.S.*, *Lond.* SYRUPUS SIMPLEX. *Ed.*, *Dub.* *Syrup. Simple Syrup.*

"Take of Sugar [refined] *two pounds and a half;* Water *a pint.* Dissolve the Sugar in the Water with the aid of heat, remove any scum which may form, and strain the solution while hot." *U. S.*

"Take of Sugar [refined] *three pounds;* Distilled Water *a pint* [Imperial measure]. Dissolve with a gentle heat." *Lond.*

"Take of Pure Sugar *ten pounds;* boiling Water *three pints* [Imperial measure]. Dissolve the Sugar in the Water with the aid of a gentle heat." *Ed.*

"Take of Refined Sugar, in powder, *five pounds* [avoirdupois]; Distilled Water *two pints* [Imp. meas.]. Dissolve the Sugar in the Water with the aid of a steam or water heat. The sp. gr. of this Syrup is 1·330." *Dub.*

This syrup, when properly prepared, is inodorous, of a sweet taste without peculiar flavour, thick, viscid, nearly colourless, and perfectly transparent. If somewhat turbid, as it is apt to be when made with sugar not well refined, it may be clarified by beating the white of an egg to a froth with three or four ounces of water, mixing this with the syrup, boiling the mixture for a short time that the albumen may coagulate, and taking off the scum which rises to the surface, or separating it by filtration through paper or flannel. Two gallons of the syrup may be thus clarified. Any colour and peculiar flavor which it may possess may be removed by treating it, at the same time, with a small proportion (about 5 per cent.) of animal charcoal.

The white of egg is beaten to a froth in order that, when it coagulates, it may be rendered by the air which it contains specifically lighter than the syrup, and thus rise to the surface. If not thus treated, it floats, when coagulated, in the syrup, or sinks to the bottom. Now it is obvious that, if the syrup and albumen be heated together, the latter must be deprived of a portion of the air which it contains, before the point of coagulation is attained, and thus be rendered less disposed to rise to the surface. Guibourt, therefore, recommends that the albumen should not be added till the syrup is boiling hot, and should then be poured into it from a height, in order to increase the quantity of air entangled in it.

M. Salles, an apothecary of Clermond-Ferrand, in France, recommends that syrups which require clarification should be treated in the following manner. Allow the liquor with which the syrup is to be prepared, without previously decanting or filtering it, to become quite cold; then mix with it the white of eggs unbeaten, in the proportion of one egg for every five or six pounds (avoirdupois) of sugar employed; and, having added the sugar or honey, boil the whole for half an hour, or until a portion of the syrup upon cooling exhibits flocculi of albumen floating in a transparent medium. During the ebullition care must be taken to agitate the syrup in such a manner as to prevent the formation of foam upon its surface. When allowed to cool, the coagulated albumen with the impurities subsides, and the clear syrup floats above, and may be drawn off or decanted. In this process the albumen sinks because not incorporated with air. M. Salles calls it clarification *per descensum*, and states that it is applicable to all syrups of a density below 30° Baumé at the boiling point. (*Journ. de Pharm.*, xxiv. 490.)

Syrup is very useful in the formation of pills and mixtures, and in various other pharmaceutical operations in which sugar in solution is required.

Off. Prep. Confectio Aromatica; Confectio Catechu Composita; Confectio Opii; Confectio Scammonii; Infusum Catechu; Mistura Creasoti; Mistura

Cretæ; Pilulæ Ferri Compositæ; Syrupus Acidi Citrici; Syrupus Ferri Iodidi; Syrupus Ipecacuanhæ; Syrupus Morphiæ Acetatis; Syrupus Morphiæ Muriatis; Syrupus Rhei Aromaticus; Syrupus Tolutanus. W.

SYRUPUS ACACIÆ. *U.S.* *Syrup of Gum Arabic.*

"Take of Gum Arabic [in lumps] *two ounces;* Sugar [refined] *fifteen ounces;* Water *eight fluidounces.* Dissolve first the Gum in the Water without heat, then the Sugar with a gentle heat, and strain." *U. S.*

The gum should be carefully selected; and if its solution contain impurities, it should be strained before the addition of the sugar. This syrup is useful in the preparation of mixtures, pills, and troches, and is a good demulcent; but unfortunately the proportion of the gum to the sugar is too small to meet all the indications calling for the conjoint use of these two substances, and could not be much increased without endangering the stability of the preparation. W.

SYRUPUS ACETI. *Ed.* *Syrup of Vinegar.*

"Take of Vinegar, French in preference, *eleven fluidounces;* Pure Sugar *fourteen ounces.* Boil them together." *Ed.*

Syrup of vinegar forms with water a refrigerant and grateful drink in fevers. It may be added to barley water and other farinaceous and mucilaginous beverages and mixtures, when a vegetable acid is not contra-indicated. W.

SYRUPUS ACIDI CITRICI. *U.S., Dub.* *Syrup of Citric Acid.*

"Take of Citric Acid, in powder, *two drachms;* Oil of Lemons *four minims;* Syrup *two pints.* Rub the Citric Acid and Oil of Lemons with a fluidounce of the Syrup, then add the mixture to the remainder of the Syrup, and dissolve with a gentle heat." *U. S.*

"Take of Citric Acid, in powder, Distilled Water, of each, *two and a half ounces* [avoirdupois]; Tincture of Lemon Peel *five fluidrachms;* Simple Syrup *three pints* [Imperial measure]. Dissolve the Acid in the Water with the aid of heat; then add the solution and Tincture of Lemon Peel to the Syrup, and mix with agitation." *Dub.*

This is more uniform in its character, keeps better, and is more readily prepared than lemon syrup, but does not equal it in flavour, if the latter is well made. It is much employed as an agreeable and refrigerant addition to drinks, especially carbonic acid water. Tartaric acid, on account of its greater cheapness, is not unfrequently substituted for the citric; but the syrup made with it does not keep so well, and, moreover, is more apt to irritate the stomach.

Off. Prep. Liquor Magnesiæ Citratis. W.

SYRUPUS ALLII. *U.S.* *Syrup of Garlic.*

"Take of Fresh Garlic, sliced and bruised, *six ounces;* Diluted Acetic Acid *a pint;* Sugar [refined], in coarse powder, *two pounds.* Macerate the Garlic in ten fluidounces of the Diluted Acetic Acid, in a glass vessel, for four days, and express the liquor. Then mix the residue with what remains of the Acid, and again express until sufficient has passed to make the whole, when filtered, measure a pint. Lastly, pour the filtered liquor on the Sugar contained in a quart bottle, and agitate till it is dissolved." *U. S.*

This preparation is made upon correct principles, as vinegar is a much better solvent of the active matter of garlic than water. The syrup is given in chronic catarrhal affections of the lungs, and is particularly beneficial in infantile cases, by the stimulus which it affords to the nervous system. A teaspoonful may be given for a dose to a child a year old. W.

SYRUPUS ALTHÆÆ. *Lond., Ed.* *Syrup of Marshmallow.*

"Take of Marshmallow [root], sliced, *an ounce and a half;* Sugar [refined] *three pounds,* or *a sufficient quantity;* Distilled Water *a pint* [Imperial measure]; Rectified Spirit *two fluidounces and a half,* or *a sufficient quantity.* Macerate

the Marshmallow in the Water for twelve hours. Express the liquor and strain through linen. Then add a weight of the Sugar double that of the strained liquor, and dissolve with a gentle heat. Finally, when the Syrup has cooled, mix with each fluidounce of it half a fluidrachm of the Spirit." *Lond.*

"Take of Althæa Root, fresh and sliced, *eight ounces;* Boiling Water *four pints* [Imp. meas.]; Pure Sugar *two pounds and a half.* Boil the Althæa Root with the Water down to two pints; strain and express strongly through calico; let the impurities subside; and dissolve the Sugar in the clear liquor with the aid of heat." *Ed.*

This syrup made according to the directions of the former London, and of the present Edinburgh Pharmacopœia, contains a considerable quantity of starch, besides mucilage, and is very liable to ferment. The French prepare it with cold water, and thus avoid the starch; and the London College has adopted this method in the last edition of the Pharmacopœia. The syrup is simply demulcent; but is not much used in this country. W.

SYRUPUS AMYGDALÆ. *U. S.* *Syrup of Almonds.* *Syrup of Orgeat.*

"Take of Sweet Almonds *a pound;* Bitter Almonds *four ounces;* Water *three pints;* Sugar [refined] *six pounds.* Having blanched the Almonds, rub them in a mortar to a very fine paste, adding, during the trituration, three fluidounces of the Water and a pound of the Sugar. Mix the paste thoroughly with the remainder of the Water, strain with strong expression, add the remainder of the Sugar to the strained liquor, and dissolve it with the aid of a gentle heat. Strain the Syrup through fine linen, and, having allowed it to cool, put it into bottles, which must be well stopped, and kept in a cool place." *U. S.*

This process corresponds closely with that of the French Codex. Orange-flower water, however, which is an ingredient of the French preparation, is wanting in ours. It may be added to the syrup in the quantity of half a pint immediately after the sugar is dissolved.

This is an elegant syrup much employed in Europe, and occasionally in this country. It is demulcent, nutritive, and, in consequence of the hydrocyanic acid of the bitter almonds, somewhat sedative. It is said to impair greatly the odour of musk and assafetida, when mixed with them. It may be added to cough mixtures, or used for flavouring drinks in complaints of the chest. W.

SYRUPUS AURANTII CORTICIS. *U. S.* SYRUPUS AURANTII. *Lond., Ed., Dub.* *Syrup of Orange Peel.*

"Take of Orange Peel, bruised, *two ounces;* Boiling Water *a pint;* Sugar [refined] *two pounds and a half.* Macerate the Orange Peel in the Water, in a covered vessel, for twelve hours, and strain; then add the Sugar, and proceed in the manner directed for Syrup." *U. S.*

The *London College* takes *two ounces and a half* of the dried peel, *a pint* [Imperial measure] of boiling distilled water, *three pounds,* or *a sufficient quantity* of refined sugar, and *two fluidounces and a half,* or *a sufficient quantity* of rectified spirit; macerates the peel in the water for twelve hours, in a covered vessel; then expresses the liquor, and boils for ten minutes; lastly, strains, and completes the process as directed for the syrup of marshmallow. The *Edinburgh College* takes the same materials in the same quantities, excepting the spirit; infuses the peel in the water for twelve hours in a covered vessel, pours off the liquor, filters if necessary, adds the sugar, and dissolves it with the aid of heat. The *Dublin College* employs *two ounces and a half* [avoirdupois] of dried bitter orange peel, *a pint* [Imp. meas.] of boiling distilled water, and *a sufficiency* of powdered refined sugar; infuses the peel in the water for twelve hours, and strains without expression; then adds to the liquor twice its weight of sugar, and dissolves with a steam or water heat.

In the preparation of this syrup, the solution of the sugar in the infusion of orange peel should be effected with as little heat as possible, in consequence of the volatile nature of the active principle of the peel; and, to facilitate the solution, the sugar should be previously powdered.

The syrup has an agreeable flavour, for which alone it is employed. Prepared according to the U. S. process, it is apt to ferment in warm weather. To obviate this result, a syrup may be made by adding a fluidounce of the tincture of orange peel to a pint of simple syrup. This preparation is little inferior to the officinal, though the presence of the spirit may in some instances be objectionable. Professor Procter proposes to prepare the syrup in the following manner. Two ounces of recently dried sweet orange peel, in powder, is subjected to percolation with a mixture of two parts of alcohol and one of water until six fluidounces are obtained; the tincture is mixed with about two and a half pounds of sugar, in coarse powder, which is then spread on paper until the alcohol has evaporated; and, finally, the sugar thus prepared is dissolved in a pint of water at a boiling heat. (*Am. Journ. of Pharm.*, xix. 97.)

Off. Prep. Confectio Aromatica. W.

SYRUPUS COCCI. *Lond.* *Syrup of Cochineal.*

"Take of Cochineal, bruised, *four scruples;* boiling Distilled Water *a pint* [Imperial measure]; Sugar [refined] *three pounds*, or *a sufficient quantity;* Rectified Spirit *two fluidounces and a half*, or *a sufficient quantity*. Boil the Cochineal in the Water for fifteen minutes, in a covered vessel, occasionally stirring, then strain and complete the preparation as directed for Syrup of Marshmallow." *Lond.* (See *Syrupus Althææ.*)

This syrup is used chiefly for imparting colour to mixtures. W.

SYRUPUS CROCI. *Lond.*, *Ed.*, *Dub.* *Syrup of Saffron.*

"Take of Saffron *five drachms;* boiling Distilled Water *a pint* [Imperial measure]; Sugar [refined] *three pounds*, or *a sufficient quantity;* Rectified Spirit *two fluidounces and a half*, or *a sufficient quantity*. Macerate the Saffron in the Water for twelve hours, in a covered vessel; then strain the liquor, and finish in the manner directed for Syrup of Marshmallow." *Lond.* (See *Syrupus Althææ.*)

The *Edinburgh College* takes *ten drachms* of saffron, an *Imperial pint* of boiling water, and *three pounds* of sugar, and proceeds in the manner directed for syrup of orange peel. The *Dublin College* infuses *half an ounce* [avoirdupois] of saffron for twelve hours in *a pint* [Imp. meas.] of boiling distilled water, boils for five minutes, strains with expression through calico, sets aside to settle, decants the clear liquor, adds twice its weight of sugar, and dissolves with a steam or water heat.

This is slightly stimulant, but is valued chiefly for its fine colour.

Off. Prep. Confectio Sulphuris. W.

SYRUPUS HEMIDESMI. *Dub.* *Syrup of Indian Sarsaparilla.*

"Take of Indian Sarsaparilla, bruised, *four ounces* [avoirdupois]; Boiling Distilled Water *one pint* [Imperial measure]; Refined Sugar, in powder, *as much as is sufficient*. Infuse the Sarsaparilla in the Water for four hours, in a covered vessel, and strain; set it by until the sediment subsides, then decant the clear liquor, and, having added to it twice its weight of sugar, dissolve with the aid of a steam or water heat." *Dub.*

This is a very weak preparation, and may be taken almost ad libitum. (See *Hemidesmus*.) W.

SYRUPUS IPECACUANHÆ. *U. S.*, *Ed.* *Syrup of Ipecacuanha.*

"Take of Ipecacuanha, in coarse powder, *an ounce;* Diluted Alcohol *a pint;* Sugar *two pounds and a half;* Water *a sufficient quantity*. Macerate the Ipecacuanha in the Alcohol for fourteen days, and filter. Evaporate the filtered

liquor to six fluidounces, again filter, and add sufficient Water to make the liquid measure a pint. Lastly, add the Sugar, and proceed in the manner directed for Syrup.

"Syrup of Ipecacuanha may also be prepared by putting the Ipecacuanha, previously moistened with Diluted Alcohol, into a percolator; pouring upon it gradually Diluted Alcohol until a pint of filtered liquor is obtained; then evaporating to six fluidounces, and completing the process as above directed." *U. S.*

"Take of Ipecacuanha, in coarse powder, *four ounces;* Rectified Spirit *one pint* [Imperial measure]; Proof Spirit and Water, of each, *fourteen fluidounces;* Syrup *seven pints.* Digest the Ipecacuanha in fifteen fluidounces of the Rectified Spirit at a gentle heat for twenty-four hours; strain, squeeze the residuum, and filter. Repeat this process with the residuum and Proof Spirit, and again with the Water. Unite the fluids, and distil off the Spirit, till the residuum amount to twelve ounces; add to the residuum five fluidounces of the Rectified Spirit, and then the Syrup." *Ed.*

By the U. S. process, a tincture of ipecacuanha is first formed with diluted alcohol, then reduced by evaporation so as to drive off the alcohol, and afterwards diluted with water and made into a syrup with sugar. The alternative of preparing the tincture by maceration or percolation is allowed; but the latter mode should be resorted to only by those experienced in the process. The French Codex dissolves the alcoholic extract of ipecacuanha in water, and then mixes it with syrup; but it is obvious that the U. S. process is preferable, as it spares the continued heat requisite to reduce the tincture to dryness. The Edinburgh process is unnecessarily complex; and the addition of the rectified spirit to the syrup, if thought necessary for its preservation, might have been dispensed with, had the direction been given to concentrate the syrup.

Mr. Laidley, of Richmond, Va., having found this syrup as ordinarily made to spoil by keeping, recommends the preparation of a fluid extract from the root by means of alcohol, and the addition of this to simple syrup in such proportion as to have the due officinal strength. It is probably owing to the substances extracted by the water of the diluted alcohol employed in the officinal process, that the syrup is liable to change. (*Am. Journ. of Pharm.*, xxvi. 103.)

This syrup is chiefly applicable to the cases of children. One fluidounce of it, prepared according to the U. S. formula, should contain the virtues of fifteen grains of ipecacuanha. The dose of it, as an emetic, is for an adult from one to two fluidounces, for a child a year or two old, from one to two fluidrachms, repeated every fifteen or twenty minutes till it acts. As an expectorant, the dose for an adult is one or two fluidrachms, for a child from five to twenty minims. The Edinburgh syrup is somewhat, but not materially weaker. W.

SYRUPUS KRAMERIÆ. *U. S.* *Syrup of Rhatany.*

"Take of Rhatany, in coarse powder, *a pound;* Sugar [refined] *two pounds and a half;* Water *a sufficient quantity.* Mix the Rhatany with a pint of Water, and, having allowed the mixture to stand for twenty-four hours, introduce it into a percolator, and gradually pour Water upon it, until four pints of filtered liquor are obtained. Evaporate this, by means of a water-bath, to seventeen fluidounces; then add the Sugar, and proceed in the manner directed for Syrup. This Syrup may also be prepared in the following manner.

"Take of Extract of Rhatany *two ounces;* Water *a pint;* Sugar *two pounds and a half.* Dissolve the extract in the Water and filter; then add the Sugar, and proceed in the manner directed for Syrup." *U. S.*

As rhatany yields a variable proportion of extract, it follows that the syrup resulting from these two modes of preparation must differ. To obviate this evil as far as possible, care should be taken, in following the first process, to select

the best rhatany, and preferably the small roots, as it is these only which will yield two ounces of good extract to the pound.

In the second process extract of rhatany as free as possible from insoluble matter should be chosen; and that prepared according to the U. S. directions will be found the best. (See *Extractum Krameriæ.*) This preparation affords a convenient mode of exhibiting rhatany to infants. The dose for an adult is half a fluidounce, for a child a year or two old, twenty or thirty minims. W.

SYRUPUS LIMONIS. *U. S.* SYRUPUS LIMONUM. *Lond., Ed. Lemon Syrup.*

"Take of Lemon-juice, strained, *a pint;* Sugar [refined] *two pounds.* Add the Sugar to the Juice, and proceed in the manner directed for Syrup." *U. S.*

"Take of Juice of Lemons, strained, *a pint* [Imp. meas.]; Sugar [refined] *two pounds and a half;* Rectified Spirit *two fluidounces and a half.* Boil the Juice for ten minutes, and strain. Add the Sugar, and dissolve. Lastly, when the Syrup has cooled, mix the Spirit with it." *Lond.*

"Take of Lemon-juice, freed from impurities by subsidence and filtration, *a pint* [Imp. meas.]; Sugar [refined] *two pounds and a half.* Dissolve the Sugar in the Lemon-juice with the aid of a gentle heat, and after twenty-four hours' rest remove the scum, and pour the clear liquor from the dregs." *Ed.*

This syrup forms a cooling and grateful addition to beverages in febrile complaints, and serves to conceal the taste of saline purgatives in solution. W.

SYRUPUS MORI. *Lond. Syrup of Mulberries.*

"Take of Mulberry Juice, strained, *a pint* [Imperial measure]; Sugar [refined] *two pounds and a half;* Rectified Spirit *two fluidounces and a half.* Dissolve the Sugar in the Mulberry Juice, with a gentle heat, and set aside for twenty-four hours; then remove the scum, and pour off the clear liquor from the dregs, if there be any. Lastly, mix the Spirit with it." *Lond.*

This may be used for the same purposes with lemon syrup. In like manner syrups may be prepared from various succulent fruits, such as *strawberries, raspberries, blackberries, currants, pineapples, &c.* When the juice is thick, it may be diluted with from one-third of its bulk to an equal bulk of water, previously to the addition of the sugar. In the preparation of *raspberry syrup,* which, as ordinarily made, is apt to gelatinize, M. Blondeau recommends that the strained juice be allowed to stand from eight to fifteen hours, according to the temperature, in order to ferment. The juice separates into two portions, the upper thick, the lower clear. The latter is to be separated by straining, and made into a syrup with the usual proportion of sugar. The new process of the London College for Syrupus Mori is in accordance with this recommendation. These syrups are employed to flavour drinks, and are much used as grateful additions to carbonic acid water.* W.

* Some practical remarks in relation to these syrups, so much used with artificial mineral water, may prove useful to the inexperienced pharmaceutist. Care should be taken that the fruit employed should be fully ripe, and freed from all its natural attachments, as calyx, stem, &c., and from all other impurities. Without being previously crushed, it should be put into canvass or woollen bags, which should be about two-thirds full when placed under the press. The expressing force should be gradually increased, so as effectually to remove the juice with as little of the tissue of the fruit as possible. It is customary to make a pint of syrup from a pint measure of fruit, and, if the expressed juice is insufficient for the purpose, to dilute it with water; but this is obviously an arbitrary rule which cannot be universally applied without injuriously affecting the character of the product. The rule in the text is better; viz., to dilute the juice when too thick. In dissolving the sugar, as short an exposure to heat as possible is desirable. Some dissolve the sugar in a portion of the juice with heat, and add the remainder a few minutes before removal from the fire. Some fruits contain so much pectin that their syrups are apt to gelatinize. This is particularly the case with currants and raspberries. A mode of preventing this result has been mentioned in the text. Another method is to add to the juice

SYRUPUS MORPHIÆ ACETATIS. *Dub.* *Syrup of Acetate of Morphia.*

"Take of Solution of Acetate of Morphia *one fluidounce;* Simple Syrup *fifteen fluidounces.* Mix with agitation." *Dub.*

SYRUPUS MORPHIÆ MURIATIS. *Dub.* *Syrup of Muriate of Morphia.*

"Take of Solution of Muriate of Morphia *one fluidounce;* Simple Syrup *seventeen fluidounces.* Mix with agitation." *Dub.*

These are mere sweetened solutions of the respective salts of morphia, and were probably intended to take the place of the syrup of poppies, omitted by the Dublin College in its Pharmacopœia of 1850. About four fluidounces of the syrups contain a grain of the respective salts. The full dose, therefore, for an adult would be from half a fluidounce to a fluidounce; for a child two years old, half a fluidrachm to a fluidrachm. W.

SYRUPUS PAPAVERIS. *Lond., Ed.* *Syrup of Poppies.*

"Take of Poppy [capsules], bruised and without seeds, *three pounds;* Sugar [refined] *five pounds;* boiling Distilled Water *five gallons* [Imperial measure]; Rectified Spirit *five fluidounces.* Boil down the Capsules in the Water to two gallons, and press strongly. Boil down the strained liquor again to four pints, and strain it while hot. Set it by for twelve hours, that the dregs may subside; then boil down the clear liquor to two pints; in this dissolve the sugar; lastly, mix in the spirit." *Lond.*

"Take of Poppy-heads, without the seeds, *one pound and a half;* boiling Water *fifteen pints* [Imperial measure]; Pure Sugar *three pounds.* Slice the Poppy-heads, infuse them in the water for twelve hours, boil down to five pints, strain, and express strongly through calico, boil again down to two pints and a half; then add the Sugar, and dissolve it with the aid of heat." *Ed.*

As the capsules contain variable proportions of the narcotic principle, the syrup prepared from them is necessarily of variable strength. It is, moreover, very apt to spoil. Its place might, with great propriety, be supplied by a syrup prepared from one of the salts of morphia, which would keep well, and have the advantage of uniform strength. Four grains of the sulphate of morphia dissolved in a pint of syrup, would afford a preparation at least equal to the average strength of the syrup of poppies, and much more certain in its operation. Mr. Southall recommends that the syrup of poppies should be prepared with a cold infusion made by percolation; the same proportions being employed as directed by the London Pharmacopœia. The virtues of the capsules are thus extracted without those principles which cause the syrup to ferment speedily. (See *Am. Journ. of Pharm.*, xv. 140.) Mr. Southall after preparing the infusion evaporates it to the proper measure before adding the sugar. Mr. Stocken prefers adding the sugar before the concentration is completed, and afterwards evaporating to 32° of the saccharometer. (*Pharm. Journ. and Trans.*, xi. 299.) It is probable that a syrup prepared with diluted alcohol as the menstruum would keep better than that made on either of the above plans.

The syrup of poppies is employed, chiefly in infantile cases, to allay cough,

after expression one-tenth of its bulk of the juice of sour cherries, allow the mixture to stand for fifteen hours, and then separate the coagulated pectin by very gentle pressure in a cloth. *Pineapple* syrup may be made either in the ordinary mode, or by slicing the fruit, alternating the slices with layers of powdered sugar, permitting them to stand twenty-four hours, and then expressing the syrup formed. Each pound of the pared fruit, with thirty ounces of sugar, should yield with the requisite quantity of water two pints of syrup. For some further practical remarks on the preparation of particular syrups, the reader is referred to a paper by Mr. Ambrose Smith in the *American Journal of Pharmacy* (xxii. 212).—*Note to the ninth edition.*

quiet restlessness, relieve pain, and promote sleep. The dose is from half a fluidrachm to a fluidrachm for an infant, from half a fluidounce to a fluidounce for an adult. W.

SYRUPUS PRUNI VIRGINIANÆ. *U. S.* *Syrup of Wild-cherry Bark.*

"Take of Wild-cherry Bark, in coarse powder, *five ounces;* Sugar [refined] *two pounds;* Water *a sufficient quantity.* Moisten the Bark thoroughly with Water, let it stand for twenty-four hours in a close vessel, then transfer it to a percolator, and pour Water upon it gradually until a pint of filtered liquor is obtained. To this add the Sugar, in a bottle, and agitate occasionally until it is dissolved." *U. S.*

This process affords a handsome syrup with the virtues of the bark unimpaired by the injurious effects of heat. It is based upon a formula proposed by Messrs. Procter and Turnpenny in the *American Journal of Pharmacy* (xiv. 27). The dose is half a fluidounce. W.

SYRUPUS RHAMNI. *Lond., Ed.* *Syrup of Buckthorn.*

"Take of Juice of Buckthorn [berries] *four pints* [Imperial measure]; Ginger, sliced, Pimento, in powder, each, *six drachms;* Sugar [refined] *four pounds;* Rectified Spirit *six fluidounces.* Set by the Juice for three days that the dregs may subside, and then strain it. To a pint of the clear Juice add the Ginger and Pimento; then macerate for four hours with a gentle heat, and strain. Boil down the remainder of the Juice to a pint and a half. Mix the liquors, and dissolve the Sugar in them. Finally, mix in the Spirit." *Lond.*

The *Edinburgh* process is the same as the above, omitting the spirit.

The syrup of buckthorn is a brisk cathartic, but, having an unpleasant taste, and being apt to gripe violently, is seldom employed. In Europe it is used occasionally with other medicines in cathartic and diuretic mixtures. The dose is from half a fluidounce to a fluidounce. The patient should drink freely of thin gruel, or other demulcent beverage, during its operation. W.

SYRUPUS RHEI. *U. S.* *Syrup of Rhubarb.*

"Take of Rhubarb, in coarse powder, *two ounces;* Alcohol *half a pint;* Water *a pint and a half;* Sugar [refined] *two pounds.* Mix the Alcohol and Water, pour four fluidounces of the liquid on the Rhubarb previously mixed with an equal bulk of sand, and allow the whole to stand four hours; then transfer the mass to a percolator, and gradually pour upon it the remainder of the mixed Alcohol and Water. When the liquor has ceased to pass, evaporate it by means of a water-bath to thirteen fluidounces, and, having added the Sugar, proceed in the manner directed for Syrup." *U. S.*

This is a mild cathartic, adapted to the cases of infants, to whom it may be given in the dose of one or two fluidrachms. W.

SYRUPUS RHEI AROMATICUS. *U. S.* *Aromatic Syrup of Rhubarb.*

"Take of Rhubarb, bruised, *two ounces and a half;* Cloves, bruised, Cinnamon, bruised, each, *half an ounce;* Nutmeg, bruised, *two drachms;* Diluted Alcohol *two pints;* Syrup *six pints.* Macerate the Rhubarb and Aromatics in the Diluted Alcohol for fourteen days, and strain; then, by means of a water-bath, evaporate the liquor to a pint, and, while it is still hot, mix it with the Syrup previously heated.

"Aromatic Syrup of Rhubarb may also be prepared by putting the Rhubarb and Aromatics, previously reduced to coarse powder and moistened with Diluted Alcohol, into an apparatus for displacement; pouring upon them gradually Diluted Alcohol until two pints of filtered liquor are obtained; then evaporating to a pint, and completing the process as above directed." *U. S.*

Of these two modes of proceeding, the first should always be preferred by those not experienced in conducting the process of filtration by displacement. In preparing the syrup, the apothecary should be careful to employ aromatics of the best quality, and to effect the evaporation of the tincture, according to the officinal direction, by means of a water-bath.

The aromatic syrup of rhubarb is a warm stomachic laxative, too feeble for adult cases, but well calculated for the bowel-complaints of infants, which are so frequent in our cities during the summer season, and as a remedy for which this preparation, or one analogous to it, has been long in use under the name of *spiced syrup of rhubarb*. The dose for an infant with diarrhœa is a fluidrachm, repeated every two hours till the passages indicate by their colour that the medicine has operated. W.

SYRUPUS RHŒADOS. *Lond., Ed. Syrup of Red Poppy.*

"Take of Red Poppy [petals] *a pound;* boiling Water *a pint* [Imperial measure]; Sugar [refined] *three pounds*, or *a sufficient quantity;* Rectified Spirit *two fluidounces and a half*, or *a sufficient quantity*. To the Water heated by a water-bath, gradually add the Petals, occasionally stirring; then, having removed the vessel, macerate for twelve hours; express the liquor with the hand, and strain, and complete the process as directed for Syrup of Marshmallow." *Lond.* (See *Syrupus Althææ*.)

The *Edinburgh* process differs from the London only in using *two pounds and a half* of sugar, and not using rectified spirit.

The object of introducing the petals into water heated by a water-bath is that they may shrink by being scalded, as otherwise they could not be completely immersed in the quantity of water directed. After this has been accomplished, they should be immediately removed from the fire, lest the liquor should become too thick and ropy. The fine red colour of this syrup is its only recommendation. It has no medical virtues, and is very liable to ferment. W.

SYRUPUS ROSÆ. *Lond.* SYRUPUS ROSÆ CENTIFOLIÆ. *Ed. Syrup of Roses.*

"Take of Hundred-leaved Roses *seven ounces;* Sugar [refined] *six pounds;* boiling Distilled Water *three pints* [Imperial measure]; Rectified Spirit *five fluidounces and a half*. Macerate the Roses in the Water for twelve hours, and strain. Evaporate the strained liquor, by means of a water-bath, to two pints; in this dissolve the Sugar. Lastly, mix in the Spirit." *Lond.*

"Take of fresh Damask-rose Petals *one pound;* boiling Water *three pints* [Imp. meas.]; Pure Sugar *three pounds*. Infuse the Petals in the Water for twelve hours, strain the liquor, and dissolve the Sugar in it with the aid of heat." *Ed.*

This syrup is gently laxative, and, on account of its mildness, may be given with advantage to infants and persons of delicate habit. It is without the fragrance of the rose; but has a reddish colour which is rendered bright red by acids, and green or yellow by alkalies. The dose is from two fluidrachms to one or two fluidounces.

Off. Prep. Confectio Cassiæ; Confectio Scammonii. W.

SYRUPUS ROSÆ GALLICÆ. *Ed., Dub. Syrup of Red Roses.*

"Take of dried Red-rose Petals *two ounces;* boiling Water *one pint;* Pure Sugar *twenty ounces*. Proceed as for the Syrup of Damask-rose." *Ed.*

The *Dublin College* boils *two ounces* [avoirdupois] of the dried petals in *a pint* [Imperial measure] of boiling distilled water, in a glass or porcelain vessel, until their colour is completely extracted; strains with expression, and allows the decoction to settle; then, having decanted the supernatant liquor, adds to it twice its weight of sugar, and dissolves with a steam or water heat.

The syrup of red roses is mildly astringent; but is valued more for its fine red colour, on account of which it is occasionally added to mixtures.

Off. Prep. Electuarium Catechu. W.

SYRUPUS SARSÆ. *Lond.* SYRUPUS SARZÆ. *Ed.* *Syrup of Sarsaparilla.*

"Take of Sarsaparilla *three pounds and a half;* Distilled Water *three gallons* [Imperial measure]; Sugar [refined] *eighteen ounces;* Rectified Spirit *two fluid-ounces.* Boil the Sarsaparilla with two gallons of the Water to a gallon; pour off the liquor, and strain it while hot. Again boil the Sarsaparilla with the rest of the Water to one-half, and strain. Mix the liquors, evaporate to two pints, and in these dissolve the Sugar. Lastly, when they have cooled, mix in the Spirit." *Lond.*

The *Edinburgh College* infuses *fifteen ounces* of the sarsaparilla in *a gallon* [Imp. meas.] of boiling water for twenty-four hours; boils down to four pints, and strains the liquor while hot; and, lastly, adds *fifteen ounces* of pure sugar, and evaporates to the consistence of syrup.

This syrup is necessarily a weak if not inert preparation; the virtues of sarsaparilla being only partially extracted by water, at least by the quantity ordinarily employed, and being injured or destroyed by long boiling. It is scarcely used in this country, our own compound syrup being preferred. W.

SYRUPUS SARSAPARILLÆ COMPOSITUS. *U.S.* *Compound Syrup of Sarsaparilla.*

"Take of Sarsaparilla, bruised, *two pounds;* Guaiacum Wood, rasped, *three ounces;* Hundred-leaved Roses, Senna, Liquorice Root, bruised, each, *two ounces;* Oil of Sassafras, Oil of Anise, each, *five minims;* Oil of Partridgeberry *three minims;* Diluted Alcohol *ten pints;* Sugar [refined] *eight pounds.* Macerate the Sarsaparilla, Guaiacum Wood, Roses, Senna, and Liquorice Root in the Diluted Alcohol for fourteen days; then express and filter. Evaporate the tincture by means of a water-bath to four pints, filter, add the Sugar, and proceed in the manner directed for Syrup. Lastly, having rubbed the Oils with a small quantity of the Syrup, mix them thoroughly with the remainder.

"Compound Syrup of Sarsaparilla may also be prepared by mixing the solid materials, excepting the Sugar, in coarse powder, with three pints of Diluted Alcohol, allowing the mixture to stand for twenty-four hours, then transferring it to a percolator, gradually pouring upon it Diluted Alcohol until ten pints have passed, and proceeding with the tincture as in the above process." *U. S.*

In the original edition of the U.S. Pharmacopœia published in 1820, a process for a syrup of sarsaparilla was adopted, intended to represent the famous French *sirop de Cuisinier.* This was very much improved in the revised edition published in 1830; and the amended process has been retained with little alteration in the subsequent editions, being the first of the two quoted above. In the original process, the sarsaparilla was subjected to long decoction with water. Now it has been proved that diluted alcohol more thoroughly extracts the acrid principle of the root, upon which its activity probably depends, than water, and that this principle is either dissipated or destroyed by the long-continued application of a boiling heat.* In the present formula, therefore, which employs diluted alcohol as the menstruum, the root is more completely exhausted of its active matter; while the heat applied to the concentration, being no higher than is requisite for the evaporation of the alcohol, is insufficient to injure the pre-

* See a paper by J. Hancock, M. D., republished in the *Journ. of the Phil. Col. of Pharm.* (i. 295); a communication by M. Béral to the *Journal de Pharmacie* (xv. 657); another by M. Soubeiran in the same Journal (xvi. 38); and a paper by T. J. Husband in the *American Journ. of Pharm.* (xv. 6).

paration. The spirituous menstruum has, moreover, the advantage of not dissolving the inert fecula, which encumbers the syrup prepared by decoction, and renders it liable to spoil. In the Pharmacopœia of 1840, the pale or hundred-leaved roses were very properly substituted for the red; as their slightly laxative property accords better with the character of the preparation. The operator should be careful to comply exactly with the directions of the Pharmacopœia in relation to the period of maceration, and the use of the water-bath. The essential oils, being intended solely to communicate an agreeable flavour, are used in very small proportion. The only objection to this process is that a portion of the resin, extracted by the alcohol from the guaiacum wood, is deposited during the evaporation of the tincture; but this is separated by the filtration directed, and is therefore of no disadvantage to the preparation.

The second process above quoted differs from the first only in preparing the tincture for evaporation by percolation instead of maceration, having been very properly substituted, at the last revision of the Pharmacopœia, for the process by percolation in the edition of 1840, in which water was employed as the menstruum, and which was found to yield a syrup having less of the sensible properties of the root than that made with diluted alcohol.* But the practitioner should be aware that much of the sarsaparilla as it exists in the market is nearly or quite inert, and should be prepared to meet with disappointment in the use of this or any other preparation, unless satisfied of the good quality of the drug from which it is made.

Corrosive sublimate, which is often given in connexion with this syrup, is said to be completely decomposed by it, being converted into calomel. M. Lepage, of Gisors, proposes as a substitute the iodohydrargyrate of potassium (see *Appendix*), which he has found not to undergo decomposition. (*Journ. de Pharm.*, 3*e sér.*, viii. 63.)

The dose of the syrup is half a fluidounce, equivalent to somewhat less than a drachm of the root, to be taken three or four times a day. W.

SYRUPUS SCILLÆ. *U.S.*, *Ed.*, *Dub.* *Syrup of Squill.*

"Take of Vinegar of Squill *a pint;* Sugar [refined] *two pounds.* Add the Sugar to the Vinegar of Squill, and proceed in the manner directed for Syrup." *U. S.*

"Take of Vinegar of Squill *three pints;* Pure Sugar, in powder, *seven pounds.* Dissolve the Sugar in the Vinegar of Squill, with the aid of a gentle heat and agitation." *Ed.*

"Take of Vinegar of Squill *eight fluidounces;* Refined Sugar, in powder, *one pound* [avoirdupois]. Dissolve the Sugar in the Vinegar of Squill with the aid of a steam or water heat." *Dub.*

This syrup is much employed as an expectorant, especially in combination with a solution of tartarized antimony. The dose is about a fluidrachm. In infantile cases of catarrh and other pectoral complaints, it is sometimes given in the same dose as an emetic. W.

SYRUPUS SCILLÆ COMPOSITUS. *U.S.* *Compound Syrup of Squill.* *Hive-syrup.*

"Take of Squill, bruised, Seneka, bruised, each, *four ounces;* Tartrate of Antimony and Potassa *forty-eight grains;* Water *four pints;* Sugar [refined] *three pounds and a half.* Pour the Water upon the Squill and Seneka, and, having

* By an unfortunate error of the press in the edition of the Pharmacopœia for 1850, in a few of the earlier sold volumes, the word *two* was substituted for *ten* in the seventh line of the second process. This was corrected as soon as discovered, and in by far the greater number of copies the sentence is properly printed. The mistake is here referred to, in order to guard as far as possible against any embarrassment, in the execution of the process, by those who may have the uncorrected volume.

boiled to one-half, strain, and add the Sugar; then evaporate to three pints, and, while the Syrup is still hot, dissolve in it the Tartrate of Antimony and Potassa.

"Compound Syrup of Squill may be advantageously prepared in the following manner by those familiar with the process of displacement.

"Take of Squill, in coarse powder, Seneka, in coarse powder, each, *four ounces;* Tartrate of Antimony and Potassa *forty-eight grains;* Alcohol *half a pint;* Water *a sufficient quantity;* Sugar *three pounds and a half.* Mix the Alcohol with two pints and a half of Water, and macerate the Squill and Seneka in the mixture for twenty-four hours. Put the whole into a percolator, and add as much Water as may be necessary to make the filtered liquor amount to three pints. Boil the liquor for a few minutes, evaporate to one-half, and strain; then add the Sugar, and evaporate until the resulting Syrup measures three pints. Lastly, dissolve the Tartrate of Antimony and Potassa in the Syrup, while it is still hot." *U. S.*

This is intended as a substitute for that very popular preparation called *Coxe's hive-syrup*, from which it differs chiefly in containing sugar instead of honey. Prepared as originally directed in the Pharmacopœia, it invariably fermented from the want of sufficient concentration. This defect was corrected at the revision of 1840, when also sugar was substituted for honey, in consequence of the uncertain consistence and constitution of the latter. It will be observed that two formulæ are given above; in the first of which the virtues of the squill and seneka are extracted by long boiling with water, in the second, by percolation with water to which a small portion of alcohol has been added. Either of them will furnish an efficient product; but the latter is preferable when skilfully performed; as it avoids in great measure the injurious influence of boiling upon the seneka, exhausts both this and the squill more readily in consequence of the addition of alcohol to the menstruum, and affords a solution of their active principles less embarrassed with inert matters calculated to favour fermentation. In this process, the filtered liquor is raised to the boiling point in order to coagulate the albumen, after which the evaporation should be conducted at a lower temperature. Mr. Laidley, of Richmond, Va., suggests that the liquor be strained immediately after the short boiling, and before the evaporation; as, if the albumen be retained in the concentrated liquor, this becomes so thick as to render filtering difficult. He also suggests that, instead of following the officinal processes, a fluid extract should be prepared from the materials with alcohol, and incorporated with simple syrup. (*Am. Journ. of Pharm.*, xxvi. 104.)*

The compound syrup of squill combines the virtues of seneka, squill, and tartar emetic, of the last of which it contains one grain in every fluidounce. It is emetic, diaphoretic, expectorant, and frequently cathartic, and may be given with advantage in mild cases of croup, in the latter stages of severe cases when the object is to promote expectoration, and in other pectoral affections in which the same indication is presented. As an emetic in inflammatory croup and infantile catarrh, we decidedly prefer a simple solution of tartar emetic in water. The dose of the compound syrup of squill is, for children, from ten drops to a fluidrachm, according to the age, and should be repeated in cases of croup every

* In the Pharmacopœia of 1830, this preparation was named *Mel Scillæ Compositum*, or compound honey of squill. The following was the officinal process: "Take of Squill, bruised, Seneka, bruised, each, *four ounces;* Tartrate of Antimony and Potassa *forty-eight grains;* Clarified Honey *two pounds.* Pour the Distilled Water upon the Squill and Seneka, and boil to one-half; strain, and add the Clarified Honey; then boil down to three pints, in which dissolve the Tartrate of Antimony and Potassa." The preparation thus made was insufficiently concentrated, measuring only 20½° Baumé, instead of 30°, which is the proper standard of density for syrup. It therefore speedily fermented. By boiling, however, down to two pints instead of three, it will have the proper consistence, and will keep much better. But in this case only 32 grains of tartar emetic should be added, so that there may still be one grain of the antimonial to each fluidounce of the syrup.

fifteen or twenty minutes till it vomits. As an expectorant for adults the dose is twenty or thirty drops. W.

SYRUPUS SENEGÆ. *U. S.* *Syrup of Seneka.*

"Take of Seneka, bruised, *four ounces;* Water *a pint;* Sugar [refined] *a pound.* Boil the Water with the Seneka to one half, and strain; then add the Sugar, and proceed in the manner directed for Syrup. Syrup of Seneka may also be prepared in the following manner.

"Take of Seneka, in coarse powder, *four ounces;* Alcohol *half a pint;* Water *a pint and a half;* Sugar [refined] *fifteen ounces.* Mix the Alcohol and Water, pour half a pint of the liquid on the Seneka, and allow the mixture to stand for twelve hours; then transfer it to a percolator, and gradually pour upon it the remainder of the menstruum. When the liquor has ceased to pass, evaporate it by means of a water-bath to half a pint, filter, and, having added the Sugar, proceed in the manner directed for Syrup." *U. S.*

The latter of these processes is preferable for an experienced operator, as it avoids the injury to the seneka resulting from long boiling, and has, moreover, the advantage of the solvent power of the alcohol added; but they who are not practically acquainted with the process of percolation should employ the former.

This is an active preparation, and affords a very convenient mode of exhibiting seneka in pectoral complaints. It may be given as a stimulant expectorant in the dose of one or two fluidrachms. W.

SYRUPUS SENNÆ. *U. S.*, *Lond.*, *Ed.* *Syrup of Senna.*

"Take of Senna *two ounces;* Fennel-seed, bruised, *an ounce;* Boiling Water *a pint;* Sugar [refined] *fifteen ounces.* Digest the Senna and Fennel-seed in the Water, with a gentle heat, for an hour; then strain, add the Sugar, and evaporate to the proper consistence." *U. S.*

"Take of Senna *three ounces and a half;* Fennel [seeds], bruised, *ten drachms;* Manna *three ounces;* boiling Distilled Water *a pint* [Imp. measure]; Molasses *three pounds.* Macerate the Senna and Fennel in the Water with a gentle heat for six hours; strongly express the liquor through linen, filter, and mix the Manna with it. Evaporate the Molasses by means of a water-bath, until a portion removed from the bath barely concretes; and to the same while yet hot add the liquor, constantly stirring, until they are mixed." *Lond.*

"Take of Senna *four ounces;* boiling Water *one pint and four fluidounces* [Imperial measure]; Treacle *forty-eight ounces.* Infuse the Senna in the Water for twelve hours; strain and express strongly through calico, so as to obtain a pint and two fluidounces at least of liquid. Concentrate the Treacle in the vapour-bath as far as possible, or till a little taken out upon a rod becomes nearly concrete on cooling; and, while the Treacle is still hot, add the infusion, stirring carefully, and removing the vessel from the vapour-bath as soon as the mixture is complete. If Alexandrian Senna be used for this preparation, it must be carefully freed of Cynanchum leaves by picking it." *Ed.*

The molasses in the Edinburgh and London syrup almost completely covers the taste of the senna; and the preparation, according to Dr. Christison, is very effectual, and seldom occasions nausea or griping. The U. S. process is liable to the objection, that considerable evaporation is necessary to bring the syrup to the proper consistence; so that, if a boiling heat be employed, the senna may be injured. This syrup is intended chiefly as a cathartic for children, to whom it may be given in the dose of one or two fluidrachms. W.

SYRUPUS TOLUTANUS. *U. S.*, *Lond.*, *Ed.*, *Dub.* *Syrup of Tolu.*

"Take of Tincture of Tolu *a fluidounce and a half;* Water *a pint;* Sugar [refined] *two pounds and a half.* Mix the Tincture with the Sugar in coarse

powder; expose the mixture, in a shallow dish, to a gentle heat until the alcohol has evaporated; then pour the Water upon it in a covered vessel, heat gradually till the Sugar is dissolved, and strain." *U. S.*

"Take of Balsam of Tolu *ten drachms;* boiling Distilled Water *a pint* [Imp. meas.]; Sugar [refined] *two pounds and a half.* Boil the Balsam in the Water for half an hour, in a covered vessel, occasionally stirring, and strain the liquor when cold; then add the Sugar and dissolve it." *Lond.*

The *Edinburgh College* prepares this syrup by adding gradually *one ounce* of the tincture of tolu to *two pounds* of simple syrup just prepared, and before it has become cold. The *Dublin College* takes *an ounce* [avoirdupois] of the balsam to *a pint* [Imp. meas.] of distilled water, and proceeds essentially as the London College.

In the U. S. and Edinburgh processes, the syrup is prepared with the tincture of tolu; in the latter by adding it to simple syrup, in the former by mixing it with the sugar employed, and evaporating the alcohol, before dissolving the sugar in the water. By the U. S. method the advantage is gained of getting rid of the alcohol with the least possible loss of volatile oil by heat. The London and Dublin process affords a syrup with a finer flavour than that prepared with the tincture, but with much waste of balsam. To obviate this waste, the same portion of balsam is, according to Mr. Braude, usually employed in successive operations, and it long continues to impart odour and taste to boiling water. The quantity of the balsam is rather more than two grains in a fluidounce of the syrup, prepared according to the U. S. Pharmacopœia, which is a little stronger than the Edinburgh, and much stronger than the London and Dublin preparation. The syrup of tolu may, therefore, be considered inert as a medicine; and its only use is to impart its agreeable flavour to mixtures.* W.

SYRUPUS VIOLÆ. *Lond., Ed. Syrup of Violets.*

"Take of fresh Violets *one pound;* Boiling Water *two pints and a half* [Imp. meas.]; Pure Sugar *seven pounds and a half.* Infuse the flowers for twenty-four hours in the Water, in a covered glass or earthenware vessel; strain without squeezing, and dissolve the Sugar in the filtered liquor." *Ed.*

"Take of Violets [recent petals] *nine ounces;* boiling Distilled Water *a pint* [Imperial measure]; Sugar [refined] *three pounds,* or *a sufficient quantity;* Rectified Spirit *two fluidounces and a half,* or *a sufficient quantity.* Macerate the Violets in the Water for twelve hours; then express, and filter. Set apart that the dregs may subside, and finish in the manner directed for Syrup of Marshmallow." *Lond.* (See *Syrupus Althææ.*)

This syrup has a deep-blue colour and an agreeable flavour. It is said that its colour is most beautiful when it is prepared in well-cleaned pewter vessels; but the action of the metal has not been satisfactorily explained. As it is apt to fade by time, it is sometimes counterfeited with materials the colour of which is more permanent. The fraud may usually be detected by the addition of an acid or alkali, the former of which reddens the syrup of violets, the latter renders it green, while they produce no such change upon the counterfeit. It should not have the smell or taste of red cabbage, a syrup from which acts in the same way with acids and alkalies.

* Mr. J. D. Finley proposes the following plan of preparing the *syrup of tolu*, which affords a syrup twice as strong as the U. S. process, and perfectly clear, whereas the officinal syrup has a somewhat milky appearance. "Take of tincture of tolu *two fluidounces*, carbonate of magnesia *two drachms*, sugar a pound and a half (Avoirdupois), water *twelve fluidounces*. Rub the tincture with the carbonate and two ounces of the sugar in powder, gradually add the water, and filter. Then dissolve the remainder of the sugar in the filtered liquid with a gentle heat." The *syrup of ginger* may be prepared in the same way. (*Am. Journ. of Pharm.*, xxiii. 220.)

The syrup acts as a gentle laxative when given to infants in the dose of one or two fluidrachms; but it is used chiefly as a test of acids and alkalies. For the latter purpose, a syrup prepared from the juice of the red cabbage may be substituted. It is very seldom kept in our shops. W.

SYRUPUS ZINGIBERIS. *U.S.*, *Lond.*, *Ed.*, *Dub.* *Ginger Syrup.*

"Take of Tincture of Ginger *four fluidounces;* Water *four pints;* Sugar [refined] *ten pounds.* Mix the Tincture with four pounds of the Sugar, in coarse powder, and expose the mixture, in a shallow dish, to a gentle heat until the alcohol has evaporated. Add the residue of the Sugar, and subsequently the Water in a covered vessel, heat gradually till the Sugar is dissolved, and strain." *U. S.*

The *London College* macerates *two ounces and a half* of sliced ginger, for four hours, in *a pint* [Imperial measure] of boiling distilled water, and, having expressed and strained the infusion, finishes the process in the manner directed for syrup of marshmallow. (See *Syrupus Althææ.*) The *Edinburgh College* infuses *two ounces and a half* of bruised ginger, for four hours, in *a pint* [Imperial measure] of boiling water, strains, adds *two pounds and a half* of pure sugar, and dissolves it with the aid of heat. The *Dublin College* mixes *a fluidounce* of tincture of ginger with *seven fluidounces* of simple syrup.

In the former U.S. process the tincture of ginger was added to syrup, as in the present Dublin process, and the alcohol was afterwards evaporated. In the late revision of the Pharmacopœia, the better plan has been adopted of adding the tincture to the sugar before its solution; as in this way the alcohol is driven off more thoroughly with less heat, and the volatile principle of the ginger is better preserved. The use of water as the menstruum in the London and Edinburgh processes encumbers the syrup with mucilage and starch, and thus renders it more liable to decomposition. (See *the note at the foot of page* 1215.)

In order that the preparation may be of the proper strength, it is necessary that the tincture should have been made with the best Jamaica ginger. The syrup of ginger is much used as a warm stomachic addition to tonic and purgative infusions or mixtures, and to impart flavour to drinks, particularly to carbonic acid water.

Off. Prep. Confectio Sulphuris; Electuarium Opii. W.

TINCTURÆ.

Tinctures.

Tinctures, in the pharmaceutical sense of the term, are solutions of medicinal substances in alcohol or diluted alcohol, prepared by maceration, digestion, or percolation. Solutions in spirit of ammonia and ethereal spirit are embraced under the same denomination, but are severally distinguished by the titles of *ammoniated tinctures* and *ethereal tinctures.* The advantages of alcohol as a menstruum are, that it dissolves principles which are sparingly or not at all soluble in water, and contributes to their preservation when dissolved; while it leaves behind some inert substances which are dissolved by water. In no instance, however, is absolute alcohol employed. The U.S. Pharmacopœia directs it of the sp. gr. 0·835; the London and Edinburgh, 0·838; and the Dublin, 0·840. When of these densities it contains water, and is capable of dissolving more or less of substances which are insoluble in anhydrous alcohol; while its solvent power, in relation to bodies soluble in that fluid, is sufficient for all practical purposes. Diluted alcohol or proof spirit is often preferable to officinal alcohol; as it is capable of extracting a larger proportion of those active principles of plants which require an aqueous menstruum, at the same time that it

is strong enough, in most instances, to prevent spontaneous decomposition, and has the advantages of being cheaper and less stimulating.* The diluted alcohol of the different Pharmacopœias is not of the same strength; that of the United States consisting of equal measures of officinal alcohol and water, and having the sp. gr. 0·935; while that of London and Dublin has the sp. gr. 0·920, and that of Edinburgh 0·912. The difference, however, is not very material. Alcohol or rectified spirit is preferred as the solvent, when the substance to be extracted or dissolved is nearly or quite insoluble in water, as in the instances of the resins, guaiac, camphor, and the essential oils. The presence of water is here injurious, not only by diluting the menstruum, but by exercising an affinity for the alcohol which interferes with its solvent power. Thus, water, added to an alcoholic solution of one of these bodies, produces a precipitate by abstracting the alcohol from it. Diluted alcohol or proof spirit is employed, when the substance is soluble both in alcohol and water, or when one or more of the ingredients are soluble in the one fluid, and one or more in the other, as in the case of those vegetables which contain extractive or tannin, or the native salts of the organic alkalies, or gum united with resin or essential oil. As these include the greater number of medicines from which tinctures are prepared, diluted alcohol is most frequently used.

In the preparation of the tinctures, the medicine should be in the dry state, and properly comminuted by being bruised, sliced, or pulverized. It is usually better in the condition of a coarse than of a very fine powder; as in the latter it is apt to agglutinate, and thus present an impediment to the penetration of the menstruum. When several substances differing in solubility are employed, they should be added successively to the spirit, those least soluble first, those most so last; as otherwise the menstruum might become saturated with the ingredient for which it has the strongest affinity, and thus be rendered incapable of dissolving a due proportion of the others.

Until recently, tinctures have been universally prepared by maceration or digestion. The Edinburgh College directs digestion to be continued usually for seven days. Our own Pharmacopœia directs maceration at ordinary temperatures, and extends the period to two weeks. The latter plan is preferable, as it is more convenient and equally effectual, the lower temperature being compensated by the longer maceration. When circumstances require that the tincture should be speedily prepared, digestion may be resorted to. Care should always be taken to keep the vessels well stopped, in order to prevent the evaporation of the alcohol. The materials should be frequently shaken during the digestion or maceration; and this caution is especially necessary when the substance acted on is in the state of powder. The tincture should not be used till the maceration is completed; when it should be separated from the dregs either by simply filtering it through paper, or, when force is requisite, by first expressing it through linen, and subsequently filtering.

The plan of preparing tinctures by percolation or displacement has recently been extensively adopted; and has been found to answer an excellent purpose, when skilfully executed. In the U. S. and Edinburgh Pharmacopœias, this mode of preparation has been given as an alternative in numerous instances; and would probably have been exclusively recommended in some, except for its

* Mr. Wm. Bastick, in a communication to the Pharmaceutical Journal and Transactions, states, as the result of his experience, that most of the tinctures prepared with proof spirit or diluted alcohol undergo deterioration by time, in consequence of acetous fermentation taking place in the alcoholic fluid. The tinctures most prone to this change are those of senna, rhubarb, columbo, henbane, digitalis, bark, hops, aloes, and the compound tincture of cinnamon. The best preventive is to keep them in full and well-closed bottles, at a low temperature. (*Am. Journ. of Pharm.*, xx. 47.)

liability to fail in the hands of inexperienced persons. The reader will find rules for the proper management of this process at *pages* 782 and 789.

Another mode of exhausting medicines by spirit has been proposed by Dr. H. Burton. It consists in suspending in the solvent, immediately under its surface, the solid matter contained loosely in a bag. The liquid in contact with the bag, becoming heavier by impregnation with the matters dissolved, sinks to the bottom; its place is supplied with a fresh portion, which in its turn sinks; and thus a current is established, which continues until the solid substance is exhausted or the liquid saturated. During the maceration, the bag should be occasionally raised above the surface of the liquor in the bottle, beneath the cover, and allowed to drain, and then again immersed. It is asserted that the period of maceration is much shortened in this way. (*Lond. Med. Gaz.*, Aug. 30, 1844.)*

Tinctures, prepared by adding alcohol to the expressed juices of plants, have been long in use on the Continent of Europe, and have been brought into notice in Great Britain. They are sometimes called in England *preserved vegetable juices.* The tinctures of some of the narcotic plants might no doubt be advantageously prepared in this way, as those of conium, hyoscyamus, and belladonna. Mr. Squire and Mr. Bentley have paid particular attention to these preparations. According to Mr. Squire, the leaves only of the plants should be used, and in the case of biennial plants those exclusively of the second year's growth; and they should always be preferably collected when the plant is in full flower. Mr. Bentley recommends the following mode of preparation. To the expressed juice, after it has stood for twenty-four hours, and deposited its feculent matter, alcohol of 0·838 is to be added in the proportion of one part by measure to four of the juice; and, after another period of twenty-four hours, the liquor is to be filtered. The proportion of alcohol mentioned has been found sufficient for the preservation of the juice, while it causes the precipitation of all the suspended mucilaginous matter.

Tinctures should be kept in bottles accurately stopped, in order to prevent evaporation, which might, in some instances, be attended with serious inconvenience, by increasing their strength beyond the officinal standard.

Medicines are most conveniently administered in tincture, which act powerfully in small doses; as the proportion of alcohol in which they are dissolved is too minute to produce an appreciable effect. Those which require to be given in large doses should be cautiously employed in this form, lest the injury done by the menstruum should more than counterbalance their beneficial operation. This remark is particularly applicable to chronic cases of disease, in which the use of tinctures is apt to result in the establishment of fatal habits of intemperance. The tinctures of the weaker medicines are more frequently given as adjuvants of other remedies than with the view of obtaining their own full effects upon the system.

The following general directions are given in the *U. S. Pharmacopœia.*

"Tinctures, when prepared by maceration, should be frequently shaken during the process, which should be conducted in glass vessels well stopped. When displacement is employed, great care should be taken to observe the directions given at page 4 [*page* 789, of this Dispensatory], so that the substances treated may be, as far as possible, exhausted of their soluble principles,

* For this mode of preparing tinctures, Mr. Samuel Gale has proposed the use of a cylindrical stoneware vessel, with a diaphragm capable of being supported at different heights by projections from the inner surface of the jar, with corresponding notches in the diaphragm, to permit its easy passage to the lower ledges. The material is to be placed upon the diaphragm and kept covered with the menstruum. (See *Am. Journ. of Pharm.*, xxii. 381, from *Pharm. Journ. and Trans.*)

and a perfectly clear tincture obtained. To those not familiar with this process, the plan of maceration is recommended."

The *London College* states that "all tinctures should be prepared in closed glass vessels, and frequently shaken during the maceration." The general directions of the *Edinburgh College*, which relate to the process of percolation, have been given at *page* 790. W.

TINCTURA ACONITI FOLIORUM. *U. S.* *Tincture of Aconite Leaves.*

"Take of Aconite Leaves *four ounces;* Diluted Alcohol *two pints.* Macerate for fourteen days, express, and filter through paper.

"This Tincture may also be prepared by thoroughly moistening the Aconite Leaves, in powder, with Diluted Alcohol, allowing the mixture to stand for twenty-four hours, then transferring it to a percolator, and gradually pouring upon it Diluted Alcohol until two pints of filtered liquor are obtained." *U. S.*

This is a good preparation of aconite when made from the recently dried leaves, and may be given in the dose of twenty or thirty drops. A saturated tincture prepared from the root is now more used. It is much stronger than the tincture of the leaves, and great care should be taken not to confound them in prescription. (See *Tinctura Aconiti Radicis.*) W.

TINCTURA ACONITI RADICIS. *U. S.* TINCTURA ACONITI. *Lond.* TINCTURA RADICIS ACONITI. *Dub.* *Tincture of Aconite Root.*

"Take of Aconite Root, well bruised, *a pound;* Alcohol *two pints.* Macerate for fourteen days, express strongly, and filter through paper.

"This Tincture may also be prepared by the process of displacement, in the following manner.

"Take of Aconite Root, in powder, *a pound;* Alcohol a *sufficient quantity.* Mix the Aconite Root with a pint of Alcohol, and allow the mixture to stand twenty-four hours; then transfer it to a percolator, and pour Alcohol gradually upon it until two pints of filtered liquor are obtained." *U. S.*

The *London College* macerates *fifteen ounces* of the coarsely powdered root in *two pints* [Imperial measure] of rectified spirit, for seven days, then expresses, and filters. The *Dublin College* takes *ten ounces* [avoirdupois] of the root, and *a pint* [Imp. meas.] of rectified spirit, and macerates for fourteen days.

This tincture, as directed in the different Pharmacopœias, may be considered of about the same strength, being probably very nearly saturated. It is much stronger than the tincture of the leaves, and too much caution cannot be observed to avoid mistaking one for the other. In preparing it, each step of the process must be carefully attended to in order to insure a favourable result. The root should be thoroughly comminuted, the maceration continued for the full period directed, and the displacing menstruum very gradually added. The dose to begin with is from five to ten drops, which may be repeated three times a day, and gradually increased, if necessary, until its peculiar effects are experienced. (See *Aconiti Radix.*) We would repeat here the caution, already given when treating of Aconite in the Materia Medica, that physicians should be careful, in prescribing either of the tinctures of aconite, to give the whole name of the one they intend, as otherwise serious consequences may ensue.* W.

* The tincture proposed by Dr. Fleming should always be expressly designated when prescribed. It is considerably stronger than the officinal; and several deaths have occurred from the use of it. The following is his formula. Take of the root, carefully dried and finely powdered, *sixteen* [troy] *ounces;* Alcohol *sixteen fluidounces.* Macerate for four days, put into a percolator, and add alcohol until twenty-four fluidounces are obtained. Not more than five drops of this should be given as a commencing dose, to be increased till its peculiar effects are experienced.

TINCTURA ALOËS: *U. S., Lond., Ed. Tincture of Aloes.*

"Take of Aloes, in powder, *an ounce;* Liquorice [extract] *three ounces;* Alcohol *half a pint;* Distilled Water *a pint and a half.* Macerate for fourteen days, and filter through paper." *U. S.*

The *London College* directs the *same quantity* of aloes (Socotrine or hepatic) and liquorice with *a pint and a half* [Imperial measure] of distilled water, and *half a pint* [Imp. meas.] of rectified spirit; macerates the aloes in the spirit for a week, then adds the liquorice, dissolves, and filters. The *Edinburgh College* takes *an ounce* of Socotrine or Indian Aloes, *three ounces* of liquorice, *twelve fluidounces* of rectified spirit, and *twenty-eight fluidounces* of water; digests for seven days; and filters the liquor, separated from the sediment.

The original tincture of aloes of the U. S. Pharmacopœia was prepared with the officinal diluted alcohol, without the addition of water. At present it corresponds with the tincture of the British Colleges. It is little more than an infusion, with the addition of sufficient alcohol to prevent spontaneous decomposition. The liquorice is added to cover the taste of the aloes; but it answers the end imperfectly; and the preparation, on account of its unpleasant bitterness, is little used, aloes being generally administered in the form of pill. The dose is from half a fluidounce to a fluidounce and a half. W.

TINCTURA ALOËS ET MYRRHÆ. *U. S., Ed.* TINCTURA ALOËS COMPOSITA. *Lond. Tincture of Aloes and Myrrh.*

"Take of Aloes, in powder, *three ounces;* Saffron *an ounce;* Tincture of Myrrh *two pints.* Macerate for fourteen days, and filter through paper." *U. S.*

The *London College* takes *four ounces* of Socotrine or hepatic aloes, *two ounces* of saffron, and *two Imperial pints* of tincture of myrrh, and proceeds as above. The *Edinburgh College* takes *four ounces* of Socotrine or Indian aloes, *two ounces* of saffron, and *two Imperial pints* of tincture of myrrh; digests for seven days; and filters the clear "superincumbent" liquor.

This tincture is a modification of the *elixir proprietatis* of Paracelsus. The saffron, which has been retained in compliance with former prejudices, can add little to the efficacy of the preparation; and, being very expensive, has with great propriety been much reduced in the U. S. formula. It serves, however, to impart a richness to the tincture, the want of which might be considered a defect by those accustomed to its use.

The tincture is purgative, tonic, and emmenagogue; and is considerably employed in chlorosis, and other disordered states of health in females, connected with suppressed, retained, or deficient menstruation, and with a constipated state of bowels. It may also be used as a stomachic laxative in cold, languid habits, independently of menstrual disorder. The dose is from one to two fluidrachms. W.

TINCTURA AMMONIÆ COMPOSITA. *Lond. Compound Tincture of Ammonia.*

"Take of Mastich *two drachms;* Rectified Spirit *nine fluidrachms;* Oil of Lavender *fourteen minims;* Stronger Solution of Ammonia *a pint* [Imperial measure]. Macerate the Mastich in the Spirit that it may be dissolved, and pour off the clear tincture; then add the other ingredients, and shake them all together." *Lond.*

This has taken the place of the *Spiritus Ammoniæ Succinatus* of the old London Pharmacopœia, and was intended as a substitute for the *eau de luce.* The oil of amber, which was retained as an ingredient with the change of name in the edition of 1836, was abandoned in that of 1851. The tincture has a milky appearance, owing to the separation of the mastich from its alcoholic solution by the water of ammonia. Its properties are essentially those of its

ammoniacal ingredient; the mastich having no medical action, and the oil of lavender being in too small proportion to serve any other purpose than that of imparting flavour. It is used chiefly as a powerful stimulant applied to the nostrils, in cases of fainting and torpor. It has considerable reputation as an antidote to the bite of venomous animals, particularly of serpents, in which it is reported to have been often used successfully. The dose for internal use is from ten to thirty drops, very largely diluted with water. W.

ESSENTIA ANISI. *Dub. Essence of Anise.*

"Take of Oil of Anise *one fluidounce;* Rectified Spirit *nine fluidounces.* Mix with agitation." *Dub.*

The Dublin College introduced into the last edition of its Pharmacopœia, under the name of *essences*, a set of preparations consisting of solutions of the aromatic volatile oils in alcohol. They are essentially tinctures, as the term is here employed; and similar preparations of the oils of peppermint and spearmint have been so named in the U.S. Pharmacopœia. They are much stronger than the spirits, which, though, like the essences, solutions of volatile oil in alcohol, are either procured by distillation, or made to imitate the distilled spirits in strength. The dose of this preparation is from twenty minims or forty drops to a fluidrachm for an adult, which may be given in sweetened water.

Off. Prep. Aqua Anisi. W.

TINCTURA ASSAFŒTIDÆ. *U.S., Lond., Ed., Dub. Tincture of Assafetida.*

"Take of Assafetida *four ounces;* Alcohol *two pints.* Macerate for fourteen days, and filter through paper." *U.S.*

The *London College* takes *five ounces* of assafetida, and *two Imperial pints* of rectified spirit, macerates for seven days, and filters. The *Edinburgh College*, with the same quantity of materials, digests for seven days, and filters the clear liquor. The *Dublin College* macerates *five ounces* [avoirdupois] with *two Imperial pints* for fourteen days, expresses, and filters.

This tincture becomes milky on the addition of water, in consequence of the separation of the resin. It possesses all the virtues of assafetida. The medium dose is a fluidrachm.

Off. Prep. Enema Fœtidum. W.

TINCTURA AURANTII. *Lond., Ed., Dub. Tincture of Orange Peel.*

"Take of dried Orange Peel *three ounces and a half;* Proof Spirit *two pints* [Imperial measure]. Macerate for seven days, then express, and filter." *Lond.*

"Take of Bitter Orange Peel, dried, *three ounces and a half;* Proof Spirit *two pints* [Imp. meas.]. Digest for seven days, strain and express strongly, and filter the liquor. This tincture may be prepared by percolation, by cutting the Peel into small fragments, macerating it in a little of the Spirit for twelve hours, and beating the mass into a coarse pulp before putting it into the percolator." *Ed.*

The *Dublin College* macerates *four ounces* [avoirdupois] of the dried bitter orange peel with *two pints* [Imp. meas.] of proof spirit, for fourteen days, strains, expresses, and filters.

It is the peel of the Seville orange which is intended by the London College; and the outer part only should be used, the inner whitish portion being inert. The tincture of orange peel is employed as a grateful addition to infusions, decoctions, and mixtures.

Off. Prep. Mistura Ferri Aromatica; Tinctura Quinæ Composita. W.

TINCTURA BELLADONNÆ. *U. S., Lond.* TINCTURA FOLIORUM BELLADONNÆ. *Dub. Tincture of Belladonna.*

"Take of Belladonna [leaves] *four ounces;* Diluted Alcohol *two pints.* Macerate for fourteen days, express, and filter through paper.

"This Tincture may also be prepared by thoroughly moistening the Belladonna, in powder, with Diluted Alcohol, allowing it to stand for twenty-four hours, then transferring it to a percolator, and gradually pouring upon it Diluted Alcohol until two pints of filtered liquor are obtained." *U. S.*

The *London College* macerates *four ounces* of dried belladonna with *two pints* [Imperial measure] of proof spirit for seven days, expresses, and filters; the *Dublin, five ounces* [avoirdupois] with *two pints* [Imp. meas.] for fourteen days, strains, expresses, and filters.

This tincture is an efficient preparation when made from the recently dried leaves; but the imported leaves are of very uncertain strength, and a tincture prepared from them is less to be relied upon than the extract. The dose is from fifteen to thirty drops. W.

TINCTURA BENZOINI COMPOSITA. *U. S., Lond., Ed. Compound Tincture of Benzoin.*

"Take of Benzoin *three ounces;* Purified Storax *two ounces;* Balsam of Tolu *an ounce;* Aloes, in powder, *half an ounce;* Alcohol *two pints.* Macerate for fourteen days, and filter through paper." *U. S.*

The *London College* takes *three ounces and a half* of benzoin, *two ounces and a half* of prepared storax, *ten drachms* of balsam of Tolu, *five drachms* of Socotrine or hepatic aloes, and *two pints* [Imperial measure] of rectified spirit, macerates for seven days, and filters. The *Edinburgh College* takes *four ounces* of benzoin, *two ounces and a half* of balsam of Peru, *half an ounce* of East India aloes, and *two pints* [Imp. meas.] of rectified spirit, digests for seven days, pours off the clear liquor, and filters it.

This tincture is a stimulating expectorant, occasionally used in chronic catarrhal affections, but more frequently as a local application to indolent ulcers. It is the *balsamum traumaticum* of the older Pharmacopœias, and may be considered as a simplified form of certain complex compositions, such as *baume de commandeur, Wade's balsam, Friar's balsam, Jesuits' drops,* &c., which were formerly in repute, and are still esteemed among the vulgar as pectorals and vulneraries. It is also an ingredient in *Turlington's balsam,* which is a popular remedy in this country for the same purposes.* It is scarcely necessary to state that the application of these preparations to fresh wounds must frequently prove injurious, by inducing too much inflammation, and thus preventing union by the first intention. The compound tincture of benzoin is decomposed by water. The dose is from thirty minims to two fluidrachms. A variety of *court plaster* is made by applying to black silk, by means of a brush, first a solution of isinglass, and afterwards an alcoholic solution of benzoin. W.

TINCTURA BUCHU. *Dub.* TINCTURA BUCKU. *Ed. Tincture of Buchu.*

"Take of Bucku *five ounces;* Proof Spirit *two pints* [Imperial measure]. Digest for seven days, pour off the clear liquor, and filter it. This tincture may be conveniently and quickly made also by the process of percolation." *Ed.*

"Take of Buchu Leaves, bruised, *five ounces* [avoirdupois]; Proof Spirit *two*

* The following is the formula for *Turlington's balsam* adopted by the Philadelphia College of Pharmacy. "Take of Alcohol Oviij., Benzoin ℥xij., Liquid Storax ℥iv., Socotrine Aloes ℥j., Peruvian Balsam ℥ij., Myrrh ℥j., Angelica Root ℥ss., Balsam of Tolu ℥iv., Extract of Liquorice Root ℥iv. Digest for ten days, and strain." (*Journ. of the Phil. Col. of Pharm.,* v. 28.)

pints [Imp. meas.]. Macerate for fourteen days, strain, express, and filter." *Dub.*

This tincture has the virtues of buchu leaves, and may be given in the dose of from one to four fluidrachms, either simply diluted with water, or as an addition to the infusion of the leaves. W.

TINCTURA CAMPHORÆ. *U. S.*, *Ed.*, *Dub.* SPIRITUS CAMPHORÆ. *Lond.* *Tincture of Camphor.*

"Take of Camphor *four ounces;* Alcohol *two pints.* Dissolve the Camphor in the Alcohol." *U. S.*

The *London College* dissolves *five ounces* of camphor in *two pints* [Imperial measure] of rectified spirit; the *Edinburgh*, *two ounces and a half* in *two pints* [Imp. meas.]; the *Dublin*, *an ounce* [avoirdupois] in *eight fluidounces.*

This is used chiefly as an anodyne embrocation in rheumatic and gouty pains, chilblains, and the inflammation resulting from sprains and bruises. It may also be employed internally, due regard being paid to the stimulant properties of the alcohol. The camphor is precipitated by the addition of water, but may be suspended by the intervention of sugar. The dose is from five drops to a fluidrachm, first added to sugar, and then mixed with water.

Off. Prep. Linimentum Ammoniæ Compositum; Mistura Camphoræ. W.

TINCTURA CANNABIS INDICÆ. *Dub.* *Tincture of Indian Hemp.*

"Take of Purified Extract of Indian Hemp *half an ounce* [avoirdupois]; Rectified Spirit *half a pint* [Imperial measure]. Dissolve the Extract in the Spirit." *Dub.*

The American reader must take care not to confound the Indian hemp, here alluded to, with the Apocynum Cannabinum known by the same name in this country. The dose, equivalent to a grain of the extract, is twenty-two minims or about forty drops, which is to be gradually increased till its effects are experienced. W.

TINCTURA CANTHARIDIS. *U. S.*, *Lond.*, *Ed.*, *Dub.* *Tincture of Spanish Flies.*

Take of Spanish Flies, bruised, *an ounce;* Diluted Alcohol, *two pints.* Macerate for fourteen days, express, and filter through paper.

"This Tincture may also be prepared by thoroughly moistening the Flies, in powder, with Diluted Alcohol, allowing them to stand for twenty-four hours, then transferring them to a percolator, and gradually pouring upon them Diluted Alcohol until two pints of filtered liquor are obtained." *U. S.*

The *London College* takes *four drachms* of the flies and *two pints* [Imperial measure] of proof spirit, macerates for seven days, expresses and filters; the *Dublin*, *half an ounce* [avoirdupois] of the former and *two pints* [Imp. meas.] of the latter, and macerates for two weeks, strains, expresses, and filters. The *Edinburgh College* takes the same proportions as the London, digests for seven days, strains, expresses the residuum strongly, and filters; or prepares the tincture by percolation, having previously moistened the coarsely powdered flies with a little of the spirit, and allowed them to stand for twelve hours.

This tincture is one of the most convenient forms for the internal use of Spanish flies, the virtues of which it possesses to their full extent. (See *Cantharis.*) It is occasionally employed externally as a rubefacient; but its liability to vesicate should be taken into consideration. The British tinctures are all too feeble; the strongest containing the virtues only of three quarters of a grain of cantharides in a fluidrachm. The dose of the U. S. tincture is from twenty drops to a fluidrachm, repeated three or four times a day. W.

TINCTURA CAPSICI. *U.S., Lond., Ed., Dub. Tincture of Cayenne Pepper.*

"Take of Cayenne Pepper *an ounce;* Diluted Alcohol *two pints.* Macerate for fourteen days, and filter through paper.

"This Tincture may also be prepared by thoroughly moistening the Cayenne Pepper, in powder, with Diluted Alcohol, putting it into a percolator, and gradually pouring upon it Diluted Alcohol until two pints of filtered liquor are obtained." *U. S.*

The *London College* takes *ten drachms* of bruised Cayenne pepper, and *two pints* (Imperial measure) of proof spirit, macerates for fourteen days, and filters; the *Dublin an ounce and a half* [avoirdupois] to *a pint* [Imp. meas.], and macerates fourteen days; the *Edinburgh* takes the same proportions as the London, digests for seven days, strains, expresses, and filters; or prepares the tincture by percolation, having previously made the capsicum into a pulp, with a little of the spirit.

This preparation of capsicum is a useful stimulant in very low states of the system with great gastric insensibility, as in malignant scarlet and typhus fevers, and in the cases of drunkards. It may also be used as a gargle, diluted with rose water or some mucilaginous fluid. (See *Capsicum.*) Applied by means of a camel's hair pencil to the relaxed uvula, it sometimes produces contraction, and relieves prolapsus of that part. The dose is one or two fluidrachms. W.

TINCTURA CARDAMOMI. *U.S., Ed. Tincture of Cardamom.*

"Take of Cardamom, bruised, *four ounces;* Diluted Alcohol *two pints.* Macerate for fourteen days, express, and filter through paper.

"This Tincture may also be prepared by thoroughly moistening the Cardamom, in powder, with Diluted Alcohol, allowing it to stand for twenty-four hours, then transferring it to a percolator, and gradually pouring upon it Diluted Alcohol until two pints of filtered liquor are obtained." *U. S.*

The *Edinburgh College* takes *four ounces and a half* of the bruised seeds, and *two pints* [Imp. meas.] of proof spirit, digests for seven days, strains, expresses, and filters; or prepares the tincture by percolation, first grinding the seeds in a coffee-mill, and making them into a pulp with a little of the spirit.

This tincture is an agreeable aromatic, and may be advantageously added to tonic and purgative infusions. The dose is one or two fluidrachms.

Off. Prep. Tinctura Conii. W.

TINCTURA CARDAMOMI COMPOSITA. *U.S., Lond., Ed., Dub. Compound Tincture of Cardamom.*

"Take of Cardamom, bruised, *six drachms;* Caraway, bruised, *two drachms;* Cinnamon, bruised, *five drachms;* Raisins, deprived of their seeds, *five ounces;* Cochineal, bruised, *a drachm;* Diluted Alcohol, *two pints and a half.* Macerate for fourteen days, express, and filter through paper." *U. S.*

"Take of Cardamom, Caraway, Cochineal, each, bruised, *two drachms and a half;* Cinnamon, bruised, *five drachms;* Raisins deprived of the seeds *five ounces;* Proof Spirit *two pints* [Imperial measure]. Macerate for seven days; then express, and filter." *Lond.*

The *Edinburgh College*, taking the same materials in the same quantities as the London, excepting cochineal, of which it takes only *a drachm*, digests for seven days, strains, expresses strongly, and filters. The same College allows the tincture to be prepared also by percolation; the solid materials being first beaten together, moistened with a little spirit, and allowed to stand for twelve hours before being introduced into the instrument. The *Dublin College* takes of cardamom and caraway, each, *half an ounce* [avoirdupois], cinnamon *an ounce* [avoird.], cochineal *two drachms* [Dub. weight], and proof spirit *two pints* [Imp. meas.], macerates for fourteen days, strains, expresses, and filters.

This is a very agreeable aromatic tincture, occasionally used as a carminative in the dose of one or two fluidrachms, but more frequently as an addition to mixtures, infusions, &c., which it renders pleasant to the taste, and acceptable to the stomach.

Off. Prep. Decoctum Aloës Compositum; Mistura Ferri Aromatica; Mistura Gentianæ Composita. W.

ESSENTIA CARUI. *Dub. Essence of Caraway.*

"Take of Oil of Caraway *one fluidounce;* Rectified Spirit *nine fluidounces.* Mix with agitation." *Dub.*

For general observations on the Dublin essences see *Essentia Anisi.* The dose of this preparation is from twenty drops to a fluidrachm.

Off. Prep. Aqua Carui. W.

TINCTURA CASCARILLÆ. *Lond., Ed., Dub. Tincture of Cascarilla.*

"Take of Cascarilla, bruised, *five ounces;* Proof Spirit *two pints* [Imperial measure]. Macerate for seven days; then express, and filter." *Lond.*

The *Edinburgh College* employs *five ounces* of the bark, in moderately fine powder, and *two pints* [Imp. meas.] of proof spirit; and proceeds by percolation or digestion as directed for the tincture of Peruvian bark. (See *Tinctura Cinchonæ.*) The *Dublin* takes *five ounces* [avoirdupois] of the bark, in coarse powder, and *two Imperial pints* of the menstruum, macerates for fourteen days, strains, expresses, and filters.

This tincture has the properties of cascarilla, but is seldom if ever used in this country. W.

TINCTURA CASSIÆ. *Ed. Tincture of Cassia.*

"Take of Cassia [Chinese cinnamon], in moderately fine powder, *three ounces and a half;* Proof Spirit *two pints* [Imperial measure]. Digest for seven days, strain, express the residuum strongly, and filter. This tincture is more conveniently made by the process of percolation, the Cassia being allowed to macerate in a little of the Spirit for twelve hours before being put into the percolator." *Ed.*

The properties of this tincture are identical with those of tincture of cinnamon. (See *Tinctura Cinnamomi.*) W.

TINCTURA CASTOREI. *U. S., Lond., Ed. Tincture of Castor.*

"Take of Castor, bruised, *two ounces;* Alcohol *two pints.* Macerate for seven days, express, and filter through paper." *U. S.*

The *London College* takes *two ounces and a half* of bruised castor, and *two Imperial pints* of rectified spirit, macerates for seven days, expresses, and filters. The *Edinburgh College* directs *two ounces and a half* of bruised castor, and *two Imperial pints* of rectified spirit, and allows the tincture to be prepared either by digestion or percolation, like the tincture of cassia.

As castor yields little if any of its virtues to water, alcohol is a better solvent than proof spirit. It is said also to form a more grateful preparation. The Russian castor should always be preferred when attainable. This tincture is used for the same purposes with castor in substance. The dose is from thirty minims to two fluidrachms. W.

TINCTURA CASTOREI AMMONIATA. *Ed. Ammoniated Tincture of Castor.*

"Take of Castor, bruised, *two ounces and a half;* Assafetida, in small fragments, *ten drachms;* Spirit of Ammonia *two pints* [Imperial measure]. Digest for seven days in a well-closed vessel; strain, and express strongly the residuum; and filter the liquor." *Ed.*

This is an active stimulant and antispasmodic, applicable to cases of severe spasm of the stomach, and to various hysterical and other nervous affections, unattended with inflammatory symptoms. The dose is from thirty minims to two fluidrachms. W.

TINCTURA CATECHU. *U. S.*, *Ed.*, *Dub.* TINCTURA CATECHU COMPOSITA. *Lond.* *Tincture of Catechu.*

"Take of Catechu *three ounces;* Cinnamon, bruised, *two ounces;* Diluted Alcohol *two pints.* Macerate for fourteen days, express, and filter through paper." *U. S.*

The *London College* takes *three ounces and a half* of powdered catechu, *two ounces and a half* of bruised cinnamon, and *two Imperial pints* of proof spirit, macerates for seven days, expresses, and filters. The *Edinburgh College* takes *three ounces and a half* of catechu, in moderately fine powder; *two ounces and a half* of cinnamon, in fine powder; and *two pints* [Imp. meas.] of proof spirit; digests for seven days, strains, expresses strongly, and filters. This College prepares the tincture also by percolation, introducing the mixed powders into the percolator without previously moistening them with spirit. The *Dublin College* macerates *four ounces* [avoirdupois] of catechu, and *two ounces* [avoird.] of cinnamon in *two Imperial pints* of proof spirit for fourteen days, strains, expresses, and filters.

This is a grateful astringent tincture, useful in all cases to which catechu is applicable, and in which small quantities of spirit are not objectionable. It may often be advantageously added to cretaceous mixtures in diarrhœa. The dose is from thirty minims to three fluidrachms, which may be given with sweetened water or some mucilaginous liquid, or in Port wine when this is not contraindicated. Like the tincture of kino, this is said sometimes to gelatinize when kept. In this state it is unfit for use. W.

TINCTURA CHIRETTÆ. *Dub.* *Tincture of Chiretta.*

"Take of Chiretta, bruised, *five ounces* [avoirdupois]; Proof Spirit *two pints* [Imperial measure]. Macerate for fourteen days, strain, express, and filter." *Dub.*

This is a tonic tincture, and may be given in the dose of one or two fluidrachms three or four times a day. W.

TINCTURA CINCHONÆ. *U. S.*, *Lond.*, *Ed.* *Tincture of Peruvian Bark.*

"Take of Yellow Bark, in powder, *six ounces;* Diluted Alcohol *two pints.* Macerate for fourteen days, express, and filter through paper.

"This Tincture may also be prepared by thoroughly moistening the Bark with Diluted Alcohol, allowing it to stand for forty-eight hours, then transferring it to a percolator, and gradually pouring upon it Diluted Alcohol until two pints of filtered liquor are obtained." *U. S.*

The *London College* orders *eight ounces* of yellow bark, and *two Imperial pints* of proof spirit, macerates for seven days, expresses, and filters.

"Take of Yellow Bark, in fine powder (or of any other species of Cinchona, according to prescription), *eight ounces;* Proof Spirit *two pints* [Imperial measure]. Percolate the Bark with the Spirit, the Bark being previously moistened with a very little Spirit, left thus for ten or twelve hours, and then firmly packed in the cylinder. This tincture may also be prepared, though much less expeditiously, and with much greater loss, by the usual process of digestion, the bark being in that case reduced to coarse powder only." *Ed.*

This tincture is very properly made with a large proportion of bark; as, in the bitter tinctures, it is important that the alcohol should bear as small a pro-

portion to the tonic principle as possible. Even when strongest, however, it cannot, in ordinary cases, be given in doses sufficiently large to obtain the full effect of the bark, without stimulating too highly. Tincture of cinchona is used chiefly as an adjunct to the infusion or decoction of bark, or the solution of sulphate of quinia, to a dose of which it may be added in the quantity of from one to four fluidrachms. W.

TINCTURA CINCHONÆ COMPOSITA. *U. S., Lond., Ed., Dub. Compound Tincture of Peruvian Bark.*

"Take of Red Bark, in powder, *two ounces;* Orange Peel, bruised, *an ounce and a half;* Virginia Snakeroot, bruised, *three drachms;* Saffron, cut, Red Saunders, rasped, each, *a drachm;* Diluted Alcohol *twenty fluidounces.* Macerate for fourteen days, express, and filter through paper.

"Compound Tincture of Peruvian Bark may be prepared from the same dry materials, by beating them well together, moistening them thoroughly with Diluted Alcohol, allowing the mixture to stand for forty-eight hours, then transferring it to a percolator, and gradually pouring upon it Diluted Alcohol until twenty fluidounces of filtered liquor are obtained." *U. S.*

"Take of Pale Bark, bruised, *four ounces;* dried Orange Peel *three ounces;* Virginia Snakeroot, bruised, *six drachms;* Saffron *two drachms;* Cochineal, bruised, *a drachm;* Proof Spirit *two pints* [Imperial measure]. Macerate for seven days, then express, and filter." *Lond.*

The *Edinburgh College* takes the same materials in the same quantities as the London, but specifies yellow bark, which it orders in coarse powder, if digestion, in fine powder, if percolation be employed. The serpentaria is directed in moderately fine powder. The process is conducted either by digesting for seven days, straining, expressing strongly, and filtering; or by percolation in the same way as compound tincture of cardamom. The *Dublin College* takes *four ounces* [avoirdupois] of pale bark, *two ounces* [avoird.] of orange peel, *six drachms* [Dub. weight] of Virginia snakeroot, *two drachms* [Dub. weight] of saffron, *one drachm* [Dub. weight] of cochineal, and *two Imperial pints* of proof spirit, macerates for fourteen days, strains, expresses, and filters.

This is the preparation commonly known by the name of *Huxham's tincture of bark.* It is unfortunate that the London and Dublin Colleges should have selected the feeblest of the officinal varieties of bark for this important tincture. The compound tincture of bark is an excellent stomachic cordial, and though too feeble in the principles of cinchona to serve as a substitute for that tonic when its full effect is required, may be very usefully employed as an addition to the decoction or infusion, or to the salts of quinia, in low forms of fever, particularly in malignant intermittents and remittents. Huxham was in the habit of uniting with it the *elixir of vitriol,* the aromatic sulphuric acid of the Pharmacopœias. The dose is from one to four fluidrachms.

Under the name of *Tinctura Cinchonæ Ferrata,* a preparation has been considerably employed in Philadelphia, of which the following formula is given by Mr. Samuel Simes, in the *Am. Journ. of Pharm.* (xxv. 402). With *one gallon* of the Edinburgh *compound tincture of bark, one ounce* of hydrated sesquioxide of iron, dried at a temperature not exceeding 130° F., is digested, and the liquor filtered. The tannic acid is removed by the iron, forming an insoluble tannate, which with the excess of oxide is separated by the filtration. In order not to lose any portion of the alkaloids which may adhere to the precipitate, this is to be well washed with boiling alcohol, the solution evaporated to dryness, the product dissolved in a little water acidulated with citric acid, and added to the filtered liquor. Lastly, *sixteen grains* of *ammonio-citrate of iron* are to be added to each fluidounce of the tincture. The dose is a fluidrachm. W.

TINCTURA CINCHONÆ PALLIDÆ. *Lond.* TINCTURA CINCHONÆ. *Dub.* *Tincture of Pale Bark.*

"Prepare this [from Pale Bark] in the manner directed for Tincture of Peruvian Bark [see *Tinctura Cinchonæ*]." *Lond.*

"Take of Crown or Pale Bark, in coarse powder, *eight ounces* [avoirdupois]; Proof Spirit *two pints* [Imperial measure]. Macerate for fourteen days, strain, express, and filter." *Dub.*

Pale bark from its general feebleness is especially inappropriate for tinctures. This preparation should be abandoned. The dose of it is one or two fluidrachms or more. W.

ESSENTIA CINNAMOMI. *Dub.* *Essence of Cinnamon.*

"Take of Oil of Cinnamon *one fluidounce;* Rectified Spirit *nine fluidounces.* Mix with agitation." *Dub.*

For general observations on the Dublin essences, see *Essentia Anisi.* The dose of this preparation is from ten to twenty drops.

Off. Prep. Aqua Cinnamomi. W.

TINCTURA CINNAMOMI. *U. S., Lond., Ed.* *Tincture of Cinnamon.*

"Take of Cinnamon, bruised, *three ounces;* Diluted Alcohol *two pints.* Macerate for fourteen days, express, and filter through paper.

"This Tincture may also be prepared by thoroughly moistening the Cinnamon, in powder, with Diluted Alcohol, allowing it to stand for forty-eight hours, then transferring it to a percolator, and gradually pouring upon it Diluted Alcohol until two pints of filtered liquor are obtained." *U. S.*

The *London College* takes *three ounces and a half* of cinnamon, and *two pints* [Imperial measure] of proof spirit, and macerates for fourteen days; the *Edinburgh, three ounces and a half* of the former, in moderately fine powder, and *two pints* [Imp. meas.] of the latter, and proceeds by percolation or digestion, as in the preparation of tincture of cassia.

This tincture has the aromatic and astringent properties of cinnamon, and may be used as an adjuvant to cretaceous mixtures, and astringent infusions or decoctions. The dose is from one to three or four fluidrachms.

Off. Prep. Infusum Digitalis. W.

TINCTURA CINNAMOMI COMPOSITA. *U.S., Lond., Ed., Dub.* *Compound Tincture of Cinnamon.*

"Take of Cinnamon, bruised, *an ounce;* Cardamom [seeds], bruised, *half an ounce;* Ginger, bruised, *three drachms;* Diluted Alcohol *two pints.* Macerate for fourteen days, express, and filter through paper.

"Compound Tincture of Cinnamon may be prepared from the same dry materials, in the state of powder, by moistening them thoroughly with Diluted Alcohol, allowing them to stand for forty-eight hours, then transferring them to a percolator, and gradually pouring upon them Diluted Alcohol until two pints of filtered liquor are obtained." *U. S.*

The *London College* orders *an ounce* of cinnamon, *half an ounce* of cardamom, *two drachms and a half* of long pepper, *the same quantity* of ginger, and *two pints* [Imperial measure] of proof spirit, macerates for a week, expresses, and filters. The *Edinburgh College* directs *an ounce* of cinnamon in coarse or fine powder, according as digestion or percolation is followed, *an ounce* of bruised cardamom seeds, *three drachms* of finely ground long pepper, and *two pints* [Imp. meas.] of proof spirit; and allows the tincture to be prepared either by digestion for seven days, straining, expressing, and filtering, or by percolation in the manner directed for compound tincture of cardamom; preferring, however,

the latter mode. The *Dublin College*, using the avoirdupois weights, takes *two ounces* of cinnamon, *an ounce* of cardamom seeds, *half an ounce* of ginger, and *two Imperial pints* of proof spirit, macerates for two weeks, strains, expresses, and filters.

This is a very warm aromatic tincture, useful in flatulence, spasm of the stomach, and gastric debility. The dose is one or two fluidrachms. W.

TINCTURA COCCI CACTI. *Dub. Tincture of Cochineal.*

"Take of Cochineal, in fine powder, *two ounces* [avoirdupois]; Proof Spirit *one pint* [Imperial measure]. Macerate for fourteen days, strain, express, and filter." *Dub.*

This is valued chiefly for imparting colour to liquid preparations. It may, however, be given internally in nervous affections in doses varying from twenty drops to a fluidrachm. W.

TINCTURA COLCHICI COMPOSITA. *Lond. Compound Tincture of Colchicum.*

"Take of Colchicum Seed, bruised, *five ounces;* Aromatic Spirit of Ammonia *two pints* [Imperial measure]. Macerate for seven days; then express, and filter." *Lond.*

This is the *Spiritus Colchici Ammoniatus* of a former London Pharmacopœia. It may be employed for the same purposes as the wine of colchicum, in cases which require or admit of an active stimulant. The dose is from thirty drops to a fluidrachm. W.

TINCTURA COLCHICI SEMINIS. *U. S.* TINCTURA COLCHICI. *Lond., Ed.* TINCTURA SEMINUM COLCHICI. *Dub. Tincture of Colchicum Seed.*

"Take of Colchicum Seed, bruised, *four ounces;* Diluted Alcohol *two pints.* Macerate for fourteen days, express, and filter through paper.

"This Tincture may also be prepared by thoroughly moistening the Colchicum Seed, in powder, with Diluted Alcohol, allowing it to stand for twenty-four hours, then transferring it to a percolator, and gradually pouring upon it Diluted Alcohol until two pints of filtered liquor are obtained." *U. S.*

The *London College* orders *five ounces* of the bruised seeds, *two Imperial pints* of proof spirit, and maceration for a week; the *Dublin*, *five avoirdupois ounces* of the former and *two Imperial pints* of the latter, and maceration for two weeks. The *Edinburgh College* takes *five ounces* of the seeds finely ground in a coffee-mill, and *two pints* [Imp. meas.] of proof spirit; and prepares the tincture in the same manner as the tincture of Peruvian bark, either by percolation or digestion; preferring, however, the former process.

It was at one time supposed that the tincture was quite as effective made from the unbruised as the bruised seeds, and corresponding advice was given under the head of Colchici Semen, in the first part of this work; but the opinion has recently been shown to have been erroneous. (*Am. Journ. of Pharm.*, xxvi. 120.)

This tincture possesses the active properties of colchicum, and may be given whenever that medicine is indicated; but the wine, which contains less alcohol, is generally preferred. The dose is from half a fluidrachm to two fluidrachms. The tincture is sometimes used as an embrocation in rheumatic, gouty, and neuralgic pains. W.

TINCTURA COLOMBÆ. *U. S.* TINCTURA CALUMBÆ. *Lond., Ed., Dub. Tincture of Columbo.*

"Take of Columbo, bruised, *four ounces;* Diluted Alcohol *two pints.* Macerate for fourteen days, express, and filter through paper.

"This tincture may also be prepared by thoroughly moistening the Columbo, in powder, with Diluted Alcohol, allowing it to stand for twenty-four hours; then transferring it to a percolator, and gradually pouring upon it Diluted Alcohol until two pints of filtered liquor are obtained." *U. S.*

The *London College* takes *three ounces* of finely sliced columbo, and *two Imperial pints* of proof spirit; the *Dublin, five avoirdupois ounces* of the former, and *two Imperial pints* of the latter; the former College macerating for seven, the latter for fourteen days. The *Edinburgh College* takes *three ounces* of columbo, in small fragments or moderately fine powder, according as digestion or percolation is followed, and *two pints* [Imp. meas.] of proof spirit; and prepares the tincture either by digesting for seven days, decanting, expressing, and filtering, or by the process of percolation, allowing the powder to be macerated with a little spirit for six hours before being put into the cylinder.

The tincture of columbo of the U. S. Pharmacopœia was, with great propriety, considerably increased in strength at the revision of 1840. The larger the proportion of the tonic is to the alcohol in these bitter tinctures, the better are they calculated to meet the indications for which they are usually prescribed. When the proportion is very small, the tonic power of the bitter is overwhelmed by the stimulant influence of the alcohol. The tincture of columbo may be added to tonic infusions or decoctions, to increase their stimulant power; but, like all the other bitter tinctures, should be used with caution. The dose is from one to four fluidrachms. W.

TINCTURA CONII. *U. S., Lond., Ed. Tincture of Hemlock.*

"Take of Hemlock Leaves *four ounces;* Diluted Alcohol *two pints.* Macerate for fourteen days, express, and filter through paper.

"This Tincture may also be prepared by thoroughly moistening the Hemlock Leaves, in powder, with Diluted Alcohol, allowing them to stand for twenty-four hours, then transferring them to a percolator, and gradually pouring upon them Diluted Alcohol until two pints of filtered liquor are obtained." *U. S.*

The *London College* takes *five ounces* of the dried leaves, and *two Imperial pints* of proof spirit, macerates for seven days, expresses, and filters.

"Take of fresh leaves of Conium *twelve ounces;* Tincture of Cardamom *half a pint* [Imp. meas.]; Rectified Spirit *one pint and a half* [Imp. meas.]. Bruise the Hemlock Leaves, express the juice strongly; bruise the residuum, pack it firmly in a percolator; transmit first the Tincture of Cardamom, and then the Rectified Spirit, allowing the spirituous liquors to mix with the expressed juice as they pass through; add gently water enough to the percolator for pushing through the Spirit remaining in the residuum. Filter the liquor after agitation." *Ed.*

The tincture of hemlock necessarily partakes of the uncertainty of the dried leaves from which it is prepared. There can be little doubt that the tincture of the Edinburgh College, made from the fresh leaves and their expressed juice, is the most efficient. Another superiority of the process of that College is the use of rectified spirit (Alcohol, U. S.), which extracts the conia, and leaves the mucilage and albumen. A preparation made by adding one measure of alcohol to four of the expressed juice, has been used in England under the name of *preserved juice of hemlock*, and is probably quite equal to the Edinburgh tincture. (See *page* 1218.) The U. S. and London Pharmacopœias have very properly excluded cardamom from this preparation; as it can have little influence upon its medical effects, and tends to obscure the odour which is an indication of the activity of the tincture. A strong odour of conia should be emitted by the tincture upon the addition of potassa. The dose is from thirty minims to a fluidrachm. W.

TINCTURA CROCI. *Ed., Dub. Tincture of Saffron.*

"Take of Saffron, chopped fine, *two ounces;* Proof Spirit *two pints* [Imperial measure]. This Tincture is to be prepared like Tincture of Cinchona, either by percolation or by digestion, the former method being the most convenient and expeditious." *Ed.*

The *Dublin College* macerates *two avoirdupois ounces* of finely chopped saffron with *an Imperial pint* of proof spirit for fourteen days, strains, expresses, and filters.

This tincture possesses all the properties of saffron; but is of little other use than to impart colour to mixtures. The dose is from one to three fluidrachms.

W.

TINCTURA CUBEBÆ. *U. S., Lond., Dub. Tincture of Cubebs.*

"Take of Cubebs, bruised, *four ounces;* Diluted Alcohol *two pints.* Macerate for fourteen days, express, and filter through paper.

"This tincture may also be prepared by thoroughly moistening the Cubebs, in powder, with Diluted Alcohol, allowing the mixture to stand for twenty-four hours, then transferring it to a percolator, and gradually pouring upon it Diluted Alcohol until two pints of filtered liquor are obtained." *U. S.*

The *London College* takes *a pound* of powdered cubebs, and *two Imperial pints* of proof spirit; the *Dublin, five avoirdupois ounces* of the former and *two Imperial pints* of the latter; the former College macerating for seven, the latter for fourteen days.

This may be used as a carminative, and has been applied with advantage to the treatment of gonorrhœa in the advanced stages. The London tincture has been greatly increased in strength, and in this respect is nearly triple that of the Dublin College. The dose of the former tincture is from half a fluidrachm to two fluidrachms or more, the larger doses being used in gonorrhœal affections.

W.

TINCTURA CUSPARIÆ. *Ed. Tincture of Angustura Bark.*

"Take of Cusparia [Angustura Bark], in moderately fine powder, *four ounces and a half;* Proof Spirit *two pints* [Imperial measure]. This Tincture is to be made like the Tincture of Cinchona, and most expeditiously by the process of percolation." *Ed.*

The tincture contains the active principles of Angustura bark, and may be given in the dose of one or two fluidrachms. W.

TINCTURA DIGITALIS. *U. S., Lond., Ed., Dub. Tincture of Foxglove.*

"Take of Foxglove *four ounces;* Diluted Alcohol *two pints.* Macerate for fourteen days, express, and filter through paper.

"This Tincture may also be prepared by thoroughly moistening the Foxglove, in powder, with Diluted Alcohol, allowing it to stand for twenty-four hours, then transferring it to a percolator, and gradually pouring upon it Diluted Alcohol until two pints of filtered liquor are obtained." *U. S.*

The *London College* directs *four ounces* of the dried leaves, *two Imperial pints* of proof spirit, and maceration for seven days; the *Dublin, five avoirdupois ounces* of the dried leaves (the larger being rejected) and *two Imperial pints* of proof spirit, and maceration for two weeks.

"Take of Digitalis, in moderately fine powder, *four ounces;* Proof Spirit *two pints* [Imp. measure]. This tincture is best prepared by the process of percolation, as directed for the Tincture of Capsicum. If forty fluidounces of Spirit be passed through, the density is 0·944, and the solid contents of a fluidounce amount to twenty-four grains. It may also be made by digestion." *Ed.*

In preparing this tincture, great attention should be paid to the selection of

the leaves, according to the rules laid down under the head of Digitalis. From a neglect of these, it is apt to be weak or inefficient. The expressed juice of the leaves, preserved by means of alcohol, would probably be found a powerful preparation. (See *page* 1218.) The tincture of foxglove possesses all the virtues of that narcotic, and affords a convenient method of administering it, especially in mixtures. The dose is from ten to twenty drops, repeated two or three times a day, and increased if necessary, but with great caution. W.

TINCTURA ERGOTÆ. *Dub. Tincture of Ergot.*

"Take of Ergot of Rye, in coarse powder, *eight ounces* [avoirdupois]; Proof Spirit *two pints* [Imperial measure]. Macerate for fourteen days, strain, express, and filter." *Dub.*

The dose of this tincture is one or two fluidrachms. W.

TINCTURA ERGOTÆ ÆTHEREA. *Lond. Ethereal Tincture of Ergot.*

"Take of Ergot, bruised, *fifteen ounces;* Ether *two pints* [Imperial measure]. Macerate for seven days, then express, and filter." *Lond.*

We doubt the propriety of this preparation. Independently of its liability to the loss of ether by evaporation, and to consequent great diversity of strength, the inert fixed oil of the ergot is extracted abundantly along with the active matter. The dose of the recently prepared tincture would be from sixty to ninety minims. W.

ESSENTIA FŒNICULI. *Dub. Essence of Fennel.*

"Take of Oil of Fennel *one fluidounce;* Alcohol *nine fluidounces.* Mix with agitation." *Dub.*

The Alcohol of the Dublin College here directed is absolute alcohol, of the sp. gr. 0·795. For general observations on the Dublin essences the reader is referred to *Essentia Anisi.* The dose of the essence of fennel is from twenty drops to a fluidrachm.

Off. Prep. Aqua Fœniculi. W.

TINCTURA GALLÆ. *U.S., Lond., Dub.* TINCTURA GALLARUM. *Ed. Tincture of Galls.*

"Take of Galls, bruised, *four ounces;* Diluted Alcohol *two pints.* Macerate for fourteen days, express, and filter through paper.

"This Tincture may also be prepared by thoroughly moistening the Galls, in powder, with Diluted Alcohol, allowing them to stand for forty-eight hours, then transferring them to a percolator, and gradually pouring upon them Diluted Alcohol until two pints of filtered liquor are obtained." *U. S.*

The *London College* directs *five ounces* of powdered galls, *two Imperial pints* of proof spirit, and maceration for seven days; the *Dublin, five avoirdupois ounces* of the galls, *two Imperial pints* of the spirit, and maceration for fourteen days. The *Edinburgh College* takes the same quantity of materials as the London, and prepares the tincture either by digestion or percolation, as directed for tincture of capsicum.

The tincture of galls is powerfully astringent; but is more used as a test than as a medicine. When long kept it ceases to evince the reactions of tannic acid, in consequence of the conversion of this into gallic acid. The dose is from one to three fluidrachms. W.

TINCTURA GENTIANÆ COMPOSITA. *U.S., Lond., Ed., Dub. Compound Tincture of Gentian.*

"Take of Gentian, bruised, *two ounces;* Orange Peel [dried] *an ounce;* Cardamom [seeds], bruised, *half an ounce;* Diluted Alcohol *two pints.* Macerate for fourteen days, express, and filter through paper.

"This Tincture may also be prepared from the same dry materials, in the state of powder, by moistening them thoroughly with Diluted Alcohol, allowing them to stand for forty-eight hours, then transferring them to a percolator, and gradually pouring upon them Diluted Alcohol until two pints of filtered liquor are obtained." *U. S.*

The *London College* takes *two ounces and a half* of sliced gentian, *ten drachms* of dried orange peel, *five drachms* of bruised cardamom, and *two Imperial pints* of proof spirit, and macerates for seven days. The *Edinburgh College* takes *two ounces and a half* of bruised gentian, *ten drachms* of bruised dried bitter orange peel, *six drachms* of canella in moderately fine powder, *half a drachm* of bruised cochineal, and *two Imperial pints* of proof spirit; digests for seven days, strains, expresses strongly, and filters; or prepares the tincture by percolation as directed for the compound tincture of cardamom. The *Dublin College*, using the avoirdupois weights, takes *three ounces* of the root, *an ounce and a half* of the peel, *half an ounce* of the seeds, and *two Imperial pints* of proof spirit, and macerates for two weeks.

This is an elegant bitter, much used in dyspepsia, and as an addition to tonic mixtures in debilitated states of the digestive organs, or of the system generally. There is, however, much danger of its abuse, especially in chronic cases. The dose is one or two fluidrachms. W.

TINCTURA GUAIACI. *U.S., Ed., Dub. Tincture of Guaiac.*

"Take of Guaiac, in powder, *half a pound;* Alcohol *two pints.* Macerate for fourteen days, and filter through paper." *U. S.*

The *Edinburgh College* takes *seven ounces* of guaiac, and *two Imperial pints* of rectified spirit; the *Dublin, eight avoirdupois ounces* of the guaiac and *two Imperial pints* of the spirit; the former digests for a week, the latter macerates for two weeks.

This tincture is given in chronic rheumatism and gout, in the dose of from one to three fluidrachms three or four times a day. As it is decomposed by water, it is most conveniently administered in mucilage, sweetened water, or milk, by which the separated guaiac is held in temporary suspension. The following is a form of tincture of guaiac which the late Dr. Dewees found very efficient in the cure of suppression of the menses, and dysmenorrhœa. "Take of the best Guaiac, in powder, *four ounces;* Carbonate of Soda or of Potassa *one drachm and a half;* Pimento, in powder, *an ounce;* Diluted Alcohol, *a pound.* Digest for a few days." Dr. Dewees directed a drachm or two of the spirit of ammonia to be added, "*pro re nata*," to four fluidounces of the tincture. (*Treat. on Dis. of Females*, A. D. 1826, p. 81.) The dose is a teaspoonful three times a day, to be gradually increased if necessary. Within our own experience, this remedy has proved highly useful in painful menstruation, given in the intervals of the attacks. The quantity of alkaline addition is too small to produce any sensible effect, and the pimento can act only as a spice; so that the virtues of the tincture reside in the guaiac, and the officinal tincture would probably be found equally effectual. W.

TINCTURA GUAIACI AMMONIATA. *U.S., Ed.* TINCTURA GUAIACI COMPOSITA. *Lond. Ammoniated Tincture of Guaiac.*

"Take of Guaiac, in powder, *four ounces;* Aromatic Spirit of Ammonia *a pint and a half.* Macerate for fourteen days, and filter through paper." *U. S.*

The *London College* takes *seven ounces* of guaiac, coarsely powdered, and *two Imperial pints* of aromatic spirit of ammonia, and macerates for seven days. The *Edinburgh College* takes *seven ounces* of guaiac and *two Imperial pints* of spirit of ammonia, and digests for seven days in a well closed vessel.

This tincture is celebrated in the treatment of chronic rheumatism. It is

more stimulating, and is thought to be more effectual than the preceding. Like that, it is decomposed by water, and should be administered in some viscid or tenacious vehicle which may hold the guaiac in suspension. The Edinburgh differs from the U. S. and London preparation in having as the menstruum the caustic "spirit of ammonia," instead of the carbonated "aromatic spirit of ammonia," and is therefore stronger in reference to the ammoniacal properties of the tincture. The dose is one or two fluidrachms. W.

TINCTURA HELLEBORI. *U. S., Lond.* *Tincture of Black Hellebore.*

"Take of Black Hellebore, bruised, *four ounces;* Diluted Alcohol *two pints.* Macerate for fourteen days, express, and filter through paper.

"This Tincture may also be prepared by thoroughly moistening the Black Hellebore, in powder, with Diluted Alcohol, allowing it to stand for forty-eight hours, then transferring it to a percolator, and gradually pouring upon it Diluted Alcohol until two pints of filtered liquor are obtained." *U. S.*

The *London College* takes *five ounces* of the bruised root, and *two Imperial pints* of proof spirit, and macerates for seven days.

This tincture, formerly called *tinctura Melampodii*, possesses the properties of black hellebore, and, upon the recommendation of Dr. Mead, has been much used in suppression of the menses. It is said to be peculiarly applicable to cases in which the grade of action is too high for the use of chalybeates. At best, however, it is an uncertain remedy, and, though frequently almost inert from the bad quality of the root, should always be administered with caution, as it is sometimes violent in its action. The dose is from thirty minims to a fluidrachm, to be taken night and morning. W.

TINCTURA HUMULI. *U. S.* Tinctura Lupuli. *Lond.* *Tincture of Hops.*

"Take of Hops *five ounces;* Diluted Alcohol *two pints.* Macerate for fourteen days, express, and filter through paper." *U. S.*

The *London College* takes *six ounces* of hops and *two Imperial pints* of proof spirit, macerates for seven days, expresses, and filters.

Hops are so light and bulky that, in the proportion directed, they absorb almost all the spirit, which, after the requisite maceration, can be separated only by strong pressure. As this absorption of the spirit obstructs its proper action on all parts of the hops, it is necessary that the mixture should be frequently stirred during the maceration. By thoroughly drying the hops and rubbing them between the hands, or by cutting and bruising them, they may be brought to a state of division which will in a great measure obviate the disadvantages alluded to. As the virtues of hops depend chiefly on the lupulin, and as the quantity of this substance is not the same in different parcels, the tincture is necessarily unequal in strength; and the tincture of lupulin itself is greatly preferable. (See *Tinctura Lupulinæ.*)

The tincture of hops is tonic and narcotic, and has been proposed as a substitute for laudanum when the latter disagrees with the patient; but little reliance can be placed upon it. The condition of disease to which it appears to be best adapted, is the wakefulness, attended with tremors and general nervous derangement, to which habitual drunkards are liable, and which frequently precedes an attack of delirium tremens. The dose is from one to three fluidrachms. W.

TINCTURA HYOSCYAMI. *U. S., Lond. Ed., Dub.* *Tincture of Henbane.*

"Take of Henbane Leaves *four ounces;* Diluted Alcohol *two pints.* Macerate for fourteen days, express, and filter through paper.

"This Tincture may also be prepared by thoroughly moistening the Henbane Leaves, in powder, with Diluted Alcohol, allowing them to stand for twenty-four hours, then transferring them to a percolator, and gradually pouring upon them Diluted Alcohol until two pints of filtered liquor are obtained." *U. S.*

The *London College* takes *five ounces* of the dried leaves, and *two Imperial pints* of proof spirit, and macerates for seven days; the *Dublin, five avoirdupois ounces* of the former and *two Imperial pints* of the latter, and macerates for two weeks. The *Edinburgh College* orders the same amount of materials as the London, the henbane being in moderately fine powder, and directs the tincture to be prepared either by digestion, or preferably, by percolation, as directed for the tincture of capsicum.

This tincture may be advantageously substituted, as an anodyne and soporific, for that of opium, when the latter disagrees with the patient, or is objectionable on account of its property of inducing constipation. When the tincture of henbane purges, as it sometimes does, it may be united with a very small proportion of laudanum. The dose is a fluidrachm. The expressed juice preserved by means of alcohol may be used for the same purposes as the tincture. (See *page* 1218.) W.

TINCTURA IODINII. *U. S.* Tinctura Iodinei. *Ed. Tincture of Iodine.*

"Take of Iodine *an ounce;* Alcohol *a pint.* Dissolve the Iodine in the Alcohol." *U. S.*

The *Edinburgh College* directs *two ounces and a half* of iodine to be dissolved, with the aid of a gentle heat and agitation, in *two Imperial pints* of rectified spirit, and the tincture to be kept in well stopped bottles.

These tinctures contain so nearly the same proportion of iodine that, for practical purposes, they may be considered identical. They have very nearly the strength of the tincture employed by Coindet, which contained one part of iodine to twelve of alcohol by weight; while the U. S. tincture contains one part of the former to about 12·7 parts of the latter. It is best to prepare the tincture in small quantities at a time; as the iodine reacts on the alcohol, especially when exposed to solar light, giving rise to chemical changes. The iodine should be thoroughly dried before being weighed out. The tincture should be kept in well stopped bottles, in order to prevent the evaporation of the alcohol, and the consequent crystallization of the iodine.

The tincture of iodine has a deep-brown colour. Sixteen minims, equal to about thirty-five drops, contain one grain of iodine. It is at present less used internally than it formerly was, in consequence of an impression that it is apt to irritate the stomach. Water decomposes the tincture, and when this is swallowed, it is supposed that the iodine is precipitated upon the mucous membrane. Besides, the tincture undergoes a gradual change when kept, owing, according to Guibourt, to the reaction between the alcohol and iodine. A portion of the latter is supposed to take hydrogen from the former, producing hydriodic acid, which combines with another portion of the iodine to form iodurettted hydriodic acid; while the place of the hydrogen in the alcohol is thought to be supplied by iodine, giving rise to another iodurettted compound. The new products are soluble in water; and consequently the tincture gradually loses by time the property of being precipitated on dilution. (*Journ. de Pharm.*, 3e *sér.*, x. 113.) Yet, from the experiments of Dr. A. Göpel, it would appear that the change is slow if the tincture is kept in the dark and at a low temperature; for in three months a specimen thus treated had lost but one per cent. of iodine. (*Pharm. Central Blatt*, No. 13, A. D. 1850.) On account of its liability to precipitation in the stomach, the tincture of iodine is now almost exclusively employed locally. Undiluted, it acts as a powerful

irritant to the skin, producing inflammation, desquamation of the cuticle, &c. Nevertheless, it is much used in this state in erysipelas, chilblains, and other cases of cutaneous and subcutaneous inflammation, and often with very happy effects. But its application requires some caution; and in erysipelas, we are in the habit rather of surrounding the inflamed surface with a border of the tincture, embracing a portion of both the sound and the diseased skin, so as to prevent the progress of the inflammation, than of attempting a complete cure by covering the whole surface affected. It has been found useful in rendering the variolous eruption abortive. It has also been employed externally in croup, the bites of serpents, and local rheumatism. It is most conveniently applied by means of a camel's hair pencil. Diluted with the camphorated tincture of soap, or other alcoholic liquid, it is sometimes employed as an embrocation in scrofulous tumours and other affections requiring the use of iodine. It is much used in the radical cure of hydrocele, as an injection into the sac; and a similar employment of it has been extended to other serous cavities morbidly distended with fluid, as in the cases of ovarian dropsy, ascites, and empyema; but in these latter affections it should be resorted to, if at all, with very great caution. In hydrocele, M. Velpeau employed it diluted with double its volume of water. In the other cases referred to it has been variously diluted with from three to ten times its bulk of water, or some demulcent liquid. To prevent the precipitation of the iodine, iodide of potassium is generally added in the proportion of from two scruples to a drachm to each fluidounce of the tincture.

The dose of the tincture is from ten to twenty drops, which may be gradually increased to thirty or forty drops, three times a day. It may be given in sweetened water, and still better in wine, when this is not contra-indicated. M. Debauque, an apothecary of Mons, has ascertained that tannic acid has the property of rendering iodine soluble in water, and states that an ounce of syrup of orange-peel in four or six ounces of water, will form a clear solution with a quantity of tincture of iodine containing five or six grains of the medicine. (*Journ. de Pharm.*, 3e *sér.*, xx. 34.) W.

TINCTURA IODINII COMPOSITA. *U.S.*, *Lond.*, *Dub.* *Compound Tincture of Iodine.*

"Take of Iodine *half an ounce;* Iodide of Potassium *an ounce;* Alcohol *a pint.* Dissolve the Iodine and Iodide of Potassium in the Alcohol." *U.S.*

The *London College* takes *an ounce* of iodine, *two ounces* of iodide of potassium, and *two Imperial pints* of rectified spirit; macerates till they are dissolved, and filters. The *Dublin College* dissolves *half an ounce* of pure iodine and *an ounce* of iodide of potassium in *an Imperial pint* of alcohol, using the avoirdupois weights.

The U. S. tincture is rather stronger than the London, the wine pint employed in the former containing about one-fifth less than the Imperial pint employed in the latter. The difference, however, is of no great practical importance. The advantage of this tincture over the simple tincture above described is, that the former may be diluted with water without decomposition; so that, when it is swallowed, iodine is not precipitated upon the mucous coat of the stomach, and will not, therefore, be so likely to produce gastric irritation. This is a good theoretical recommendation; but we are by no means confident that the difference of the two preparations in irritating properties will be found very striking in practice. The compound tincture of iodine may be given internally for all the purposes which iodine is capable of answering. The dose is from fifteen to thirty drops, to be gradually increased if necessary. W.

TINCTURA JALAPÆ. *U.S.*, *Lond.*, *Ed.*, *Dub.* *Tincture of Jalap.*

"Take of Jalap, in powder, *six ounces;* Diluted Alcohol *two pints.* Macerate for fourteen days, express, and filter through paper.

"This Tincture may also be prepared by moistening the Jalap thoroughly with Diluted Alcohol, allowing it to stand for forty-eight hours, then transferring it to a percolator, and gradually pouring upon it Diluted Alcohol until two pints of filtered liquor are obtained." *U. S.*

The *London College* takes *five ounces* of coarsely powdered jalap, and *two Imperial pints* of proof spirit; the *Dublin*, *five avoirdupois ounces* of the root and *two Imperial pints* of the spirit; the former macerates for a week, the latter for two weeks. The *Edinburgh College* orders *seven ounces* of jalap, in moderately fine powder, and *two Imperial pints* of proof spirit, and allows the tincture to be prepared either by digestion or percolation, as directed for tincture of cinchona.

This tincture possesses the medical virtues of jalap, and is sometimes added to cathartic mixtures in the quantity of one or two fluidrachms, to increase their activity. W.

TINCTURA KINO. *U. S., Lond., Ed. Tincture of Kino.*

"Take of Kino, in powder, *six drachms;* Diluted Alcohol *a sufficient quantity.* Mix the Kino with an equal bulk of sand, and, having introduced it into a percolator, pour Diluted Alcohol gradually upon it until eight fluidounces of filtered liquor are obtained.

"This Tincture should be renewed frequently, and kept in closely stopped bottles; as it is apt to deteriorate rapidly by exposure." *U. S.*

The *London College* takes *three ounces and a half* of powdered kino and *two Imperial pints* of rectified spirit, macerates for a week, and filters. The *Edinburgh College* takes the same ingredients in the same proportion, and digests for a week.

This tincture very frequently becomes gelatinous if kept, and at length almost entirely loses its astringency. The character of the chemical reaction which takes place, remains to be investigated. The air has some effect; for if this is entirely excluded the tincture keeps for a long time without undergoing the change. The apothecary should introduce it when prepared into very small bottles, which should be kept well corked, and only opened when wanted for use. It is in consequence of its tendency to gelatinize, that the U. S. Pharmacopœia directs it to be frequently renewed. The dose is one or two fluidrachms. It is used chiefly as an addition to cretaceous and other astringent mixtures in diarrhœa. W.

TINCTURA KRAMERIÆ. *U. S., Dub. Tincture of Rhatany.*

"Take of Rhatany, in powder, *six ounces;* Diluted Alcohol *two pints.* Macerate for fourteen days, express, and filter through paper.

"This Tincture may also be prepared by moistening the Rhatany thoroughly with Diluted Alcohol, allowing it to stand for forty-eight hours, then transferring it to a percolator, and gradually pouring upon it Diluted Alcohol until two pints of filtered liquor are obtained." *U. S.*

The *Dublin College* takes *eight avoirdupois ounces* of the root, and *two Imperial pints* of proof spirit; macerates for two weeks, strains, expresses, and filters.

According to F. Boudet, the tincture of rhatany sometimes gelatinizes like that of kino (*Journ. de Pharm.*, 3e *sér.*, i. 338); and the same observation has been made by others. The same precaution, therefore, should be observed, in relation to the mode of keeping it, as recommended in reference to tincture of kino. This is a good preparation of rhatany in cases which admit of the use of small quantities of alcohol. The dose is one or two fluidrachms. W.

TINCTURA LACTUCARII. *Ed. Tincture of Lactucarium.*

"Take of Lactucarium, in fine powder, *four ounces;* Proof Spirit *two pints*

[Imperial measure]. This tincture is best prepared by percolation as directed for Tincture of Myrrh; but may also be prepared by digestion with coarse powder of Lactucarium." *Ed.*

The dose of this tincture is from thirty minims to two fluidrachms. W.

TINCTURA LIMONIS. *Dub.* TINCTURA LIMONUM. *Lond.* *Tincture of Lemon Peel.*

"Take of fresh Lemon Peel *three ounces and a half;* Proof Spirit *two pints* [Imperial measure]. Macerate for seven days; then express, and filter." *Lond.*

The *Dublin College* macerates *five avoirdupois ounces* of the fresh peel, cut thin, in *an Imperial pint* of proof spirit for two weeks, strains, expresses, and filters.

This tincture forms a grateful aromatic addition to tonic and purgative infusions, mixtures, &c. It may be used in the dose of one or two fluidrachms.

Off. Prep. Syrupus Acidi Citrici. W.

TINCTURA LOBELIÆ. *U.S., Lond., Ed., Dub.* *Tincture of Lobelia.*

"Take of Lobelia [the herb] *four ounces;* Diluted Alcohol *two pints.* Macerate for fourteen days, express, and filter through paper.

"This Tincture may also be prepared by thoroughly moistening the Lobelia, in powder, with Diluted Alcohol, allowing it to stand for twenty-four hours, then transferring it to a percolator, and gradually pouring upon it Diluted Alcohol until two pints of filtered liquor are obtained." *U. S.*

The *London College* takes *five ounces* of the herb, and *two Imperial pints* of proof spirit, and macerates for a week; the *Dublin*, *five avoirdupois ounces* of the former, and *two Imperial pints* of the latter, and macerates for two weeks. The *Edinburgh College* directs the same quantities as the London; and states that the tincture is best prepared by percolation as directed for tincture of capsicum, though it may also be made by digestion.

This tincture possesses the emetic and narcotic properties of lobelia, and is sometimes used in asthma, in the dose of one or two fluidrachms, repeated every two or three hours till its effects are experienced. The emetic dose is half a fluidounce. W.

TINCTURA LOBELIÆ ÆTHEREA. *Ed., Lond.* *Ethereal Tincture of Lobelia.*

"Take of dry Lobelia, in moderately fine powder, *five ounces;* Spirit of Sulphuric Ether *two pints* [Imperial measure]. This Tincture is best prepared by percolation, as directed for Tincture of Capsicum; but it may also be obtained by digestion in a well closed vessel for seven days." *Ed.*

The *London College* orders *five ounces* of powdered lobelia, *fourteen fluidounces* of ether, and *twenty-six fluidounces* of rectified spirit, macerates for seven days, expresses, and filters.

The stimulant operation of the ether in this preparation can scarcely favour the relaxing and nauseating action for which lobelia is usually employed. The dose is the same as that of the alcoholic tincture. W.

TINCTURA LUPULINÆ. *U. S., Dub.* TINCTURA LUPULI. *Ed.* *Tincture of Lupulin.*

"Take of Lupulin *four ounces;* Alcohol *two pints.* Macerate for fourteen days, and filter through paper." *U. S.*

The *Dublin* process corresponds closely with that of the U.S. Pharmacopœia, *five avoirdupois ounces* of the lupulin, and *two Imperial pints* of rectified spirit being used.

"Take *any convenient quantity* of Hops, recently dried; separate by friction and sifting the yellowish-brown powder attached to their scales. Then take of

this powder *five ounces*, and of Rectified Spirit *two pints* [Imperial measure], and prepare the tincture by percolation or digestion, as directed for Tincture of Capsicum." *Ed.*

This is much superior to the tincture of hops of the first United States Pharmacopœia, in the place of which it was introduced into the second edition. In the original preparation, a certain quantity of hops was directed, from which the lupulin was to be separated by beating, and then digested in alcohol. As hops contain a variable proportion of lupulin, a tincture thus made must be of unequal strength; an objection to which the tincture of hops, even as now prepared, is in some measure liable. (See *Tinctura Humuli.*) Besides, the amount of lupulin contained in any quantity of hops upon which alcohol can conveniently act, is too small in proportion to the alcohol, to afford a tincture of the due strength. The tincture of lupulin is, therefore, in all respects, preferable. The dose is one or two fluidrachms, to be given in sweetened water or some mucilaginous fluid. W.

TINCTURA MATICO. *Dub.* *Tincture of Matico.*

"Take of Matico Leaves, in coarse powder, *eight ounces* [avoirdupois]; Proof Spirit *two pints* [Imperial measure]. Macerate for fourteen days, strain, express, and filter." *Dub.*

The dose of this tincture is from one to three fluidrachms. W.

ESSENTIA MYRISTICÆ MOSCHATÆ. *Dub.* *Essence of Nutmeg.*

"Take of [volatile] Oil of Nutmeg *one fluidounce;* Stronger Spirit *nine fluidounces.* Mix with agitation." *Dub.*

For general observations on the Dublin essences see *Essentia Anisi.* The stronger spirit here used is alcohol of the sp. gr. 0·818. The dose of this preparation is twenty or thirty drops. W.

TINCTURA MYRRHÆ. *U. S.*, *Lond.*, *Ed.*, *Dub.* *Tincture of Myrrh.*

"Take of Myrrh, bruised, *four ounces;* Alcohol *three pints.* Macerate for fourteen days, and filter through paper." *U. S.*

The *London College* takes *three ounces* of powdered myrrh, and *two Imperial pints* of rectified spirit, and macerates for a week. The *Dublin College* takes *four avoirdupois ounces* of bruised myrrh, *two Imperial pints* of rectified spirit, and macerates for two weeks.

"Take of Myrrh, in moderately fine powder, *three ounces and a half;* Rectified Spirit *two pints* [Imperial measure]. Pack the Myrrh very gently without any Spirit in a percolator; then pour on the Spirit, and when thirty-three fluidounces have passed through, agitate well to dissolve the oleo-resinous matter which first passes, and which lies at the bottom. This tincture is much less conveniently obtained by the process of digestion for seven days." *Ed.*

Officinal alcohol is preferable, as a solvent of myrrh, to that fluid mixed with water; because it forms a perfectly clear solution, which is not attainable with the latter menstruum. The addition of water to the tincture renders it turbid. The tincture of myrrh is scarcely ever used internally. As a local application it is employed to stimulate indolent and foul ulcers, and promote the exfoliation of bones, and, diluted with water, is applied to spongy gums, aphthous sore mouth, and ulcerations of the throat. The dose, as a stimulant expectorant and emmenagogue, is from thirty minims to a fluidrachm.

Off. Prep. Tinctura Aloës et Myrrhæ. W.

TINCTURA NUCIS VOMICÆ. *U. S.* *Tincture of Nux Vomica.*

"Take of Nux Vomica, rasped, *eight ounces;* Alcohol *two pints.* Macerate for fourteen days, express, and filter through paper.

"This Tincture may also be prepared by moistening the Nux Vomica thoroughly with alcohol, allowing it to stand for two days, then transferring it to a percolator, and very gradually pouring Alcohol upon it until two pints of filtered liquor are obtained." *U. S.*

Should the operator have recourse to the second of these processes, it is of the greatest importance that the nux vomica should be well powdered; and, in consequence of the difficult action of solvents on this substance, probably from the presence of bassorin, the preliminary maceration should be continued for at least a week.

The tincture is not an eligible form for administering nux vomica, as it is equally uncertain with the medicine in substance, and has the disadvantage of excessive bitterness. The alcoholic extract, or strychnia is preferable. The dose of the tincture is from five to twenty drops. It is sometimes employed externally in cases of local paralysis. W.

TINCTURA OLEI MENTHÆ PIPERITÆ. *U. S.* ESSENTIA MENTHÆ PIPERITÆ. *Dub.* *Tincture of Oil of Peppermint. Essence of Peppermint.*

"Take of Oil of Peppermint *two fluidounces;* Alcohol *a pint.* Dissolve the Oil in the Alcohol." *U. S.*

The *Dublin College* dissolves *a fluidounce* of the oil in *nine fluidounces* of its stronger spirit (alcohol, sp. gr. 0·818).

This is a very popular preparation, which has long been kept in the shops under the name of *essence of peppermint*, and was adopted for the first time in the U. S. Pharmacopœia of 1840. It affords a convenient method of hastily administering a dose of the oil of peppermint; being of such a strength that, when dropped on loaf sugar, it may be taken without inconvenience by the patient. The dose is from ten to twenty drops, which may be given as just mentioned, or mixed with sweetened water.

Off. Prep. Aquæ Menthæ Piperitæ. W.

ESSENTIA MENTHÆ PULEGII. *Dub.* *Essence of European Pennyroyal.*

"Take of Oil of [European] Pennyroyal *one fluidounce;* Rectified Spirit *nine fluidounces.* Mix with agitation." *Dub.*

This preparation is seldom or never used in the United States. It may be given in the dose of from fifteen to thirty drops.

Off. Prep. Aqua Menthæ Pulegii. W.

TINCTURA OLEI MENTHÆ VIRIDIS. *U. S.* ESSENTIA MENTHÆ VIRIDIS. *Dub.* *Tincture of Oil of Spearmint. Essence of Spearmint.*

"Take of Oil of Spearmint *two fluidounces;* Alcohol *a pint.* Dissolve the Oil in the Alcohol." *U. S.*

The *Dublin College* dissolves *a fluidounce* of the oil in *nine fluidounces* of its stronger spirit (alcohol of the sp. gr. 0·818).

The remarks made upon the tincture of oil of peppermint are applicable also to the present tincture. The dose of the *essence of spearmint* is from twenty to forty drops.

Off. Prep. Aqua Menthæ Viridis. W.

TINCTURA OPII. *U. S., Lond., Ed., Dub.* *Tincture of Opium. Laudanum.*

"Take of Opium, in powder, *two ounces and a half;* Diluted Alcohol *two pints.* Macerate for fourteen days, express, and filter through paper." *U. S.*

The *London College* takes *three ounces* of opium, in powder, and *two Imperial pints* of proof spirit, macerates for seven days, expresses, and filters. The *Dublin*

College macerates *three avoirdupois ounces* of coarsely powdered opium in *two Imperial pints* of proof spirit for fourteen days, strains, expresses, and filters.

"Take of Opium, sliced, *three ounces;* Rectified Spirit *one pint and seven fluidounces* [Imperial measure]; Water *thirteen fluidounces and a half.* Digest the Opium in the Water at a temperature near 212° for two hours; break down the Opium with the hand; strain, and express the infusion; macerate the residuum in the Rectified Spirit for about twenty hours, and then strain and express very strongly. Mix the watery and spirituous infusions, and filter.

"This Tincture is not easily obtained by the process of percolation; but when the Opium is of fine quality, it may be prepared thus. Slice the Opium finely; mix the Spirit and Water; let the Opium macerate in fourteen fluidounces of the mixture for twelve hours, and then break it down thoroughly with the hand; pour the whole pulpy mass and fluid into a percolator, and let the fluid part pass through; add the rest of the Spirit without packing the Opium in the cylinder, and continue the process of percolation till two pints are obtained." *Ed.*

The proportion of opium in the several officinal formulæ is so nearly the same that the resulting tinctures may be considered identical. The apparent difference between the formulæ of the London and Edinburgh Colleges and ours will vanish, when the relative value of the Imperial measure, which they employ, and the wine measure of our Pharmacopœia is estimated. The Dublin preparation is somewhat weaker than the others from the use of the avoirdupois ounce. The drying and powdering of the opium, directed in all the Pharmacopœias except the Edinburgh, is clearly a useful provision; as it ensures greater uniformity in the strength of the tincture. Crude opium contains variable proportions of moisture; and laudanum prepared from a moist specimen will obviously be weaker than that from an equal weight of the dried. The pulverization ensures the previous drying of the drug, and is thus useful independently of the greater facility which it gives to the action of the menstruum. It is troublesome, however, and is often neglected. Innovation in so important a preparation, and one in which uniformity of strength is so desirable, should be avoided, unless clearly shown to be necessary. For these reasons we object to the Edinburgh formula, and greatly prefer the old standard of the U. S., London, and Dublin Pharmacopœias.

In the United States and Great Britain, this tincture is universally known by the name of *laudanum.* As this term was formerly applied to other preparations of opium, and still continues to be so on the continent of Europe, the tincture is sometimes distinguished by the epithet *liquidum*, which, however, is seldom used in this country. *Tinctura Thebaica* is another title by which the preparation is known.

About two-thirds of the opium used in the preparation of the tincture are dissolved, the residue consisting chiefly of inert matter. Allowing the opium to be wholly exhausted of its active principles, one grain would be represented by 12·8 minims, according to the U. S. formula; but a minute quantity of morphia has been detected in the residuary matter, so that the tincture is rather weaker than the proportion of opium employed would indicate. The difference, however, is insufficient to be of any practical importance.

The tincture of opium is used for all the purposes to which opium itself is applied. (See *Opium.*) The dose, equivalent to a grain of opium, is about thirteen minims, or twenty-five drops. Mr. Phillips, in his translation of the London Pharmacopœia of 1836, states that, by evaporating the tincture, and also by determining the quantity of opium left undissolved, he found the preparation to contain one grain of opium in 19 minims; and this quantity, therefore, is given as the dose equivalent to a grain of opium. But this mode of calculation is obviously fallacious; as the portion of the drug dissolved is much

more active than that left behind by the menstruum. Indeed, so feeble is the latter, that Dr. Garrod recently gave thirty grains of the residue to a healthy adult without effect. (*Pharm. Journ. and Trans.*, xi. 252.) It should be recollected that a fluidrachm or teaspoonful of laudanum (sixty minims), will afford, on an average, about one hundred and twenty drops. Laudanum, when long kept, with occasional exposure to the air, becomes thick, in consequence of the evaporation of a portion of the alcohol, and the deposition of opium. If given in this state, it often acts with unexpected energy; and cases of death have resulted in infants from its use in doses which would have been entirely safe if the tincture had been clear.

Denarcotized laudanum may be prepared by substituting the extract of opium in half the quantity for the opium itself, and previously to the maceration in diluted alcohol, exhausting it of the narcotina by ether.*

Off. Prep. Enema Opii; Linimentum Opii. W.

TINCTURA OPII ACETATA. *U. S.* *Acetated Tincture of Opium.*

"Take of Opium, in powder, *two ounces;* Vinegar *twelve fluidounces;* Alcohol *half a pint.* Rub the Opium with the Vinegar; then add the Alcohol, and, having macerated for fourteen days, express, and filter through paper." *U. S.*

This preparation was introduced into the second edition of our Pharmacopœia as a substitute for the *Acetum Opii* or *black drop* of the original work, the advantages of which it was supposed to possess, without being liable to the same objection of uncertainty of strength. The Acetum Opii, however, having maintained its standing in the estimation of the profession, and of the public, was restored, in the edition of 1840, to its officinal rank, but so modified as to ensure a preparation as uniform as is consistent with the variable quality of the opium used. (See *page* 797.) At the same time the formula for the acetated tincture was retained, as affording a useful preparation of the drug. It was originally employed by the late Dr. Joseph Hartshorne, of Philadelphia.

The acetated tincture of opium may often be advantageously used in cases in which laudanum or opium itself produces unpleasant effects, such as nausea and vomiting, intense headache, great nervous disorder, &c.; but the introduction of the salts of morphia into use has in a great measure superseded the necessity of this preparation. The dose is ten minims, or about twenty drops, equivalent to a grain of opium. W.

* *Elixir of Opium.* Under this name have been sold different liquid preparations of opium, consisting mainly, in all probability, of an aqueous solution, with sufficient alcohol to preserve it. A formula of this kind was published by Mr. Eugene Dupuy, of New York, in the *Am. Journ. of Pharm.* (xxiii. 211). Professor Procter in the same place gives a formula, differing from that of Mr. Dupuy in the employment of ether, so as to obtain at one operation a preparation analogous to the denarcotized laudanum mentioned in the text. The following is the formula referred to:—Take of opium, in powder, *ten drachms;* ether, alcohol, each, *four fluidounces;* water *a sufficient quantity.* Macerate the opium in half a pint of water for two days and express; subject the dregs to two successive macerations, using six fluidounces of water each time, with expression; mix and strain the liquors, and evaporate to two fluidounces; agitate the liquid with ether several times during half an hour, and then separate the ether by means of a funnel; evaporate the residue to dryness, dissolve the extract in half a pint of cold water, pour the solution on a filter, and after it has passed wash the filter with sufficient water to make the filtrate measure twelve fluidounces; lastly, add the alcohol and mix. This affords a liquid preparation of about the same strength as laudanum, containing the native meconate of morphia, without narcotina, and deprived of the unpleasant odour, and perhaps other more or less offensive ingredients of opium. The dose equivalent to a grain of opium is about thirteen minims; but in drops less than that of the tincture, as the elixir is much less alcoholic. Professor Procter has found, from numerous trials made at our request, that the average number of drops equivalent to thirteen minims is seventeen.—*Note to the tenth edition.*

TINCTURA OPII AMMONIATA. *Ed. Ammoniated Tincture of Opium.*

"Take of Benzoic Acid, and Saffron, chopped, of each, *six drachms;* Opium sliced, *half an ounce;* Oil of Anise *a drachm;* Spirit of Ammonia *two pints* [Imperial measure]. Digest for seven days, and then filter." *Ed.*

This tincture is used in Scotland under the title of *paregoric elixir;* but differs both in composition and strength from the preparation known by that name in the United States. Some doubts have been entertained whether it contains morphia. It is well known that ammonia precipitates morphia from its solutions; but a great excess of ammonia redissolves the precipitate. To decide the question, Mr. Gilbert, of Nottingham, submitted several portions of the tincture to a chemical examination, and was unable to detect morphia in them. (See *Med. Exam.*, iv. 493.) But we are not informed by the experimenter, whether the tincture was prepared, as directed by the College, with the Edinburgh spirit of ammonia, which is a strong alcoholic solution of the caustic alkali, or with the London spirit, which is a comparatively feeble solution of carbonate of ammonia. In the former case the ammonia, according to Dr. Christison, is in sufficient excess to hold the morphia in solution. At best, however, the preparation is of doubtful propriety; as, if the ammoniacal spirit should not happen to have the due strength, or if the ammonia should escape or become carbonated by exposure, the strength of the tincture would be affected. It is employed in spasmodic complaints, such as hooping-cough and asthma. Eighty minims should contain about a grain of opium. W.

TINCTURA OPII CAMPHORATA. *U. S., Ed., Dub.* TINCTURA CAMPHORÆ COMPOSITA. *Lond. Camphorated Tincture of Opium. Paregoric Elixir.*

"Take of Opium, in powder, Benzoic Acid, each, *a drachm;* Oil of Anise *a fluidrachm;* Clarified Honey *two ounces;* Camphor *two scruples;* Diluted Alcohol *two pints.* Macerate for fourteen days, and filter through paper." *U. S.*

The *London College* takes *fifty grains* of camphor, *seventy-two grains* of powdered opium, *the same quantity* of benzoic acid, *a fluidrachm* of oil of anise, and *two Imperial pints* of proof spirit, macerates for seven days, and filters. The *Edinburgh College* directs *fifty grains* of camphor, *four scruples* of opium, *four scruples* of benzoic acid, *a fluidrachm* of oil of anise, and *two Imperial pints* of proof spirit, and digests for a week. The *Dublin College* takes *a drachm and a half* [Dub. weight] of coarsely powdered opium, *the same quantity* of benzoic acid, *a drachm* [Dub. weight] of camphor, *a fluidrachm* of the oil of anise, and *two Imperial pints* of proof spirit, and macerates for two weeks.

This is the well-known *paregoric elixir.* It is a very pleasant anodyne and antispasmodic, much used to allay cough in chronic catarrh, asthma, consumption, pertussis, &c.; to relieve nausea and slight pains in the stomach and bowels; to check diarrhœa; and, in infantile cases, to procure sleep. Half a fluidounce of the U. S. and London tincture contains rather less than a grain of opium; of the Edinburgh and Dublin, about a grain. Liquorice, which was directed in a former edition of the U. S. Pharmacopœia, was omitted in that of 1840, in consequence of giving to the preparation the dark colour of laudanum, and thus leading to mistake. The dose for an infant is from five to twenty drops, for an adult from one to two fluidrachms.*

Off. Prep. Mistura Glycyrrhizæ Composita. W.

* The following formulæ have been adopted by the Philadelphia College of Pharmacy for the preparation of the two compound tinctures of opium, so much used under the names of *Bateman's drops* and *Godfrey's cordial.* So long as these nostrums are employed, it is important that they should be prepared in a uniform manner, and of a certain

ESSENTIA PIMENTÆ. *Dub.* *Essence of Pimento.*

"Take of Oil of Pimento *one fluidounce;* Rectified Spirit *nine fluidounces.* Mix with agitation." *Dub.*

For general observations on the Dublin essences see *Essentia Anisi.* The dose of this preparation is from thirty to sixty drops.

Off. Prep. Aqua Pimentæ. W.

TINCTURA QUASSIÆ. *U. S., Ed.* *Tincture of Quassia.*

"Take of Quassia, rasped, *two ounces;* Diluted Alcohol *two pints.* Macerate for fourteen days, express, and filter through paper.

"This Tincture may also be prepared by moistening the Quassia thoroughly with Diluted Alcohol, allowing it to stand for forty-eight hours, then transferring it to a percolator, and gradually pouring upon it Diluted Alcohol until two pints of filtered liquor are obtained." *U. S.*

The *Edinburgh College* takes *ten drachms* of quassia, and *two Imperial pints* of proof spirit, and digests for a week.

In the edition of the U. S. Pharmacopœia of 1840, the proportion of the quassia to the menstruum was very judiciously doubled. A tonic tincture can scarcely contain too large a proportion of the active ingredient. The Edinburgh preparation is much too feeble.

This tincture may be employed as an addition to tonic infusions or mixtures in the dose of one or two fluidrachms. It is a pure and intense bitter. W.

TINCTURA QUASSIÆ COMPOSITA. *Ed.* *Compound Tincture of Quassia.*

"Take of Cardamom seeds, bruised, and Cochineal, bruised, of each, *half an ounce;* Cinnamon, in moderately fine powder, and Quassia, in chips, of each, *six drachms;* Raisins *seven ounces;* Proof Spirit *two pints* [Imperial measure]. Digest for seven days, strain the liquor, express strongly the residuum, and filter. This Tincture may also be obtained by percolation, as directed for Compound Tincture of Cardamom, provided the Quassia be rasped or in powder." *Ed.*

This is tonic and aromatic, and may be given in the dose of one or two fluidrachms. W.

TINCTURA QUINÆ COMPOSITA. *Lond.* *Compound Tincture of Quinia.*

"Take of Disulphate [Sulphate, *U. S.*] of Quinia *five drachms and a scruple;* Tincture of Orange Peel *two pints* [Imperial measure]. Digest for seven days, or until it is dissolved, and filter." *Lond.*

A fluidrachm of this preparation, containing a grain of the sulphate of quinia, may be given for a dose. W.

strength; as serious consequences may happen from diversity in the formulæ, when so active a substance as opium is the chief ingredient. Such diversity has existed to a very great extent; so much so that in one formula for Bateman's drops the quantity of opium was seven and a half grains to the pint, while in another it exceeded one hundred grains. It was in order to remedy this evil, that the College was induced to adopt the formulæ here presented.

"*Bateman's pectoral drops.* Take of Diluted Alcohol Cong. iv., Red Saunders, rasped, ℥ij. Digest for twenty-four hours, filter, and add of Opium in powder ℥ij, Catechu in powder ℥ij., Camphor ℥ij., Oil of Anise f℥iv. Digest for ten days." This preparation is about equal in strength to the camphorated tincture of opium or paregoric elixir of the U. S. Pharmacopœia, containing about two grains of opium to the fluidounce.

"*Godfrey's cordial.* Take of Tincture of Opium Oiss., Molasses (from the sugar refiners) Oxvj., Alcohol Oij., Water Oxxvj., Carbonate of Potassa ℥iiss., Oil of Sassafras f℥iv. Dissolve the Carbonate of Potassa in the Water, add the Molasses, and heat over a gentle fire till they simmer; take off the scum which rises, and add the Laudanum and Oil of Sassafras, having previously mixed them well together." This preparation contains the strength of rather more than one grain of opium in a fluidounce. (*Journ. of the Phil. Col. of Pharm.*, v. 26 and 27.)

TINCTURA RHEI. *U. S., Ed. Tincture of Rhubarb.*

"Take of Rhubarb, bruised, *three ounces;* Cardamom [seeds], bruised, *half an ounce;* Diluted Alcohol *two pints.* Macerate for fourteen days, express, and filter through paper.

"This Tincture may also be prepared by thoroughly moistening the Rhubarb and Cardamom, in powder, with Diluted Alcohol, allowing them to stand for forty-eight hours, then transferring them to a percolator, and gradually pouring upon them Diluted Alcohol until two pints of filtered liquor are obtained." *U. S.*

The *Edinburgh College* takes *three ounces and a half* of rhubarb, in moderately fine powder, *half an ounce* of bruised cardamom seeds, and *two Imperial pints* of proof spirit; and prepares the tincture, like that of cinchona, either by percolation or by digestion. W.

TINCTURA RHEI COMPOSITA. *Lond., Dub. Compound Tincture of Rhubarb.*

"Take of Rhubarb, sliced, *two ounces and a half;* fresh Liquorice Root, bruised, *six drachms;* Ginger, bruised, Saffron, each, *three drachms;* Proof Spirit *two pints* [Imperial measure]. Macerate for seven days; then express, and filter." *Lond.*

The *Dublin College* employs *three avoirdupois ounces* of bruised rhubarb, *one avoirdupois ounce* of bruised cardamom seeds, *half an avoirdupois ounce* of bruised liquorice root, *two drachms* [Dub. weight] of saffron, chopped fine, and *two Imperial pints* of proof spirit; and macerates for two weeks. W.

TINCTURA RHEI ET ALOES. *U. S., Ed. Tincture of Rhubarb and Aloes.* ELIXIR SACRUM. *Sacred Elixir.*

"Take of Rhubarb, bruised, *ten drachms;* Aloes, in powder, *six drachms;* Cardamom [seeds], bruised, *half an ounce;* Diluted Alcohol *two pints.* Macerate for fourteen days, express, and filter through paper." *U. S.*

The *Edinburgh College* takes *an ounce and a half* of rhubarb, in moderately fine powder, *six drachms* of Socotrine or East India aloes, in moderately fine powder, *five drachms* of bruised cardamom seeds, and *two Imperial pints* of proof spirit; mixes the dry materials, and proceeds as for the tincture of cinchona. W.

TINCTURA RHEI ET GENTIANÆ. *U. S., Ed. Tincture of Rhubarb and Gentian.*

"Take of Rhubarb, bruised, *two ounces;* Gentian, bruised, *half an ounce;* Diluted Alcohol *two pints.* Macerate for fourteen days, express, and filter through paper.

"This Tincture may also be prepared by thoroughly moistening the Rhubarb and Gentian, in powder, with Diluted Alcohol, allowing them to stand for forty-eight hours, then transferring them to a percolator, and gradually pouring upon them Diluted Alcohol until two pints of filtered liquor are obtained." *U. S.*

The *Edinburgh College* takes *two ounces* of rhubarb, in moderately fine powder, *half an ounce* of gentian, finely cut or in coarse powder, and *two Imperial pints* of proof spirit; mixes the powders, and proceeds as for tincture of cinchona.

The above tinctures of rhubarb are all in a greater or less degree purgative, stomachic, and tonic; but, except in low states of the system, or in cases of individuals accustomed to the use of ardent spirits, they are too feebly cathartic in proportion to their stimulant power, to be advantageously employed, unless as adjuvants to other medicines. Combined with the neutral salts or other laxatives, or with tonic and stomachic infusions, mixtures, &c., they serve to render

them warmer and more cordial to the stomach, and often prove beneficial in flatulent colic, dyspepsia, the costiveness of cold and irritable habits, diarrhœa, and other analogous complaints. One of them is to be preferred to another, according as its peculiar composition may, in the judgment of the practitioner, appear to adapt it to the circumstances of the case under treatment. In low forms of fever, when the indication is to evacuate the bowels, and at the same time stimulate the patient, the simple tincture (*Tinctura Rhei*) may be advantageously used in doses of two or three fluidrachms, repeated at proper intervals till it operates. The ordinary dose of these tinctures, as purgatives, is from half a fluidounce to a fluidounce; as stomachics, from one to two or three fluidrachms. W.

TINCTURA RHEI ET SENNÆ. *U. S.* *Tincture of Rhubarb and Senna.*

"Take of Rhubarb, bruised, *an ounce;* Senna *two drachms;* Coriander [seeds], bruised, Fennel-seed, bruised, each, *a drachm;* Red Saunders, rasped, *two drachms;* Saffron, Liquorice [extract], each, *half a drachm;* Raisins, deprived of their seeds, *half a pound;* Diluted Alcohol *three pints.* Macerate for fourteen days, express, and filter through paper." *U. S.*

This is the stomachic so well known, and so much used in this country, under the name of *Warner's gout cordial.* It is a feeble purgative, usually acceptable to the stomach, and well adapted to cases of costiveness, with gastric uneasiness, in persons of a gouty habit, and accustomed to the free use of wine or other stimulant drink. The dose is from half a fluidounce to two fluidounces. W.

ESSENTIA ROSMARINI. *Dub.* *Essence of Rosemary.*

"Take of Oil of Rosemary *one fluidounce;* Rectified Spirit *nine fluidounces.* Mix with agitation." *Dub.*

For some general observations on the Dublin essences, see *Essentia Anisi.* This preparation is used as an addition to rubefacient liniments, and may be given internally in the dose of from thirty to sixty drops, or about half that number of minims. W.

TINCTURA SANGUINARIÆ. *U. S.* *Tincture of Bloodroot.*

"Take of Bloodroot, bruised, *four ounces;* Diluted Alcohol *two pints.* Macerate for fourteen days, express, and filter through paper.

"This Tincture may also be prepared by thoroughly moistening the Bloodroot, in powder, with Diluted Alcohol, allowing it to stand for forty-eight hours, then transferring it to a percolator, and gradually pouring upon it Diluted Alcohol until two pints of filtered liquor are obtained." *U. S.*

This will prove emetic in the dose of three or four fluidrachms; but it is rather intended to act as a stimulant to the stomach, expectorant, or alterative, for which purposes it may be given in the quantity of from thirty to sixty drops. W.

TINCTURA SAPONIS CAMPHORATA. *U. S.* LINIMENTUM SAPONIS. *Lond., Ed., Dub.* *Camphorated Tincture of Soap.*

"Take of Soap [Castile soap], in shavings, *four ounces;* Camphor *two ounces;* Oil of Rosemary *half a fluidounce;* Water *four fluidounces;* Alcohol *two pints.* Mix the Alcohol and Water, digest the Soap with the mixture by means of a water-bath till it is dissolved; then filter, and add the Camphor and Oil." *U. S.*

The *London College* takes *two ounces and a half* of soap, *ten drachms* of camphor, *eighteen fluidounces* of spirit of rosemary, and *two fluidounces* of distilled water; mixes the water with the spirit, then adds the soap and camphor, and macerates, with occasional agitation, till they are dissolved. The *Edinburgh College* takes *five ounces* of Castile soap, *two ounces and a half* of camphor, *six*

fluidrachms of oil of rosemary, and *two Imperial pints* of rectified spirit; digests the soap in the spirit for three days, adds the camphor and oil, and agitates briskly. The *Dublin College* dissolves *two avoirdupois ounces* of powdered Castile soap in *sixteen fluidounces* of proof spirit with a gentle heat, then adds *an avoirdupois ounce* of camphor; and, when it is dissolved, filters through paper, or allows it to stand, and decants the clear liquor.

It is necessary, in preparing this tincture, that the soap employed should not have been made with animal oil, as otherwise the preparation will not be fluid at ordinary temperatures. The soap indicated by the U. S. Pharmacopœia is that "prepared from soda and olive oil," commonly called *Castile soap.* Made according to the directions of the U. S. Pharmacopœia of 1840, the tincture was unable to retain the soap in solution, and, therefore, coagulated more or less on cooling. This defect was corrected in the edition of 1850, by the addition of water; and a similar reformation has been made in the London and Dublin processes, the latter using proof spirit, instead of the spirit of rosemary. This preparation has been usually called *soap liniment*, a name which more properly belongs to the *Linimentum Saponis Camphoratum* of the U. S. Pharmacopœia, or common *opodeldoc.*

The camphorated tincture of soap is much used, as an anodyne and gently rubefacient embrocation, in sprains, bruises, and rheumatic or gouty pains.

Off. Prep. Linimentum Opii. W.

TINCTURA SCILLÆ. *U. S., Lond., Ed., Dub. Tincture of Squill.*

"Take of Squill *four ounces;* Diluted Alcohol *two pints.* Macerate for fourteen days, express, and filter through paper.

"This Tincture may also be prepared by thoroughly moistening the Squill, in powder, with Diluted Alcohol, allowing it to stand for twenty-four hours, then transferring it to a percolator, and gradually pouring upon it Diluted Alcohol, until two pints of filtered liquor are obtained." *U. S.*

The *London College* takes *five ounces* of recently dried squill and *two Imperial pints* of proof spirit, and macerates for seven days; the *Dublin, five avoirdupois ounces* of the former and *two Imperial pints* of the latter, and macerates for fourteen days. The *Edinburgh College* takes *five ounces* of coarsely powdered squill, and *two Imperial pints* of proof spirit, and proceeds by percolation, as for the tincture of Peruvian bark, but without pressing the pulp firmly in the percolator. The College also allows the tincture to be prepared by digestion from the sliced bulb.

This tincture possesses all the virtues of squill, and may be given for the same purposes, whenever the spirituous menstruum is not objectionable. The dose as an expectorant or diuretic is from ten to twenty minims (twenty to forty drops), and the latter quantity frequently nauseates. W.

TINCTURA SENNÆ COMPOSITA. *Lond., Dub. Compound Tincture of Senna.*

"Take of Senna *three ounces and a half;* Caraway [seeds], bruised, *three drachms and a half;* Cardamom [seeds], bruised, *a drachm;* Raisins, deprived of seeds, *five ounces;* Proof Spirit *two pints* [Imperial measure]. Macerate for seven days; then express, and filter." *Lond.*

The *Dublin College* takes *four avoirdupois ounces* of senna, *half an avoirdupois ounce* of caraway, *the same quantity* of cardamom seeds, and *two Imperial pints* of proof spirit, and macerates for fourteen days.

This tincture is the *elixir salutis* of the old Pharmacopœias. It is a warm cordial purgative, useful in costiveness attended with flatulence, and in atonic gout, especially when occurring in intemperate persons. It is also added to

cathartic infusions and mixtures. The dose is from two fluidrachms to a fluidounce or more. W.

TINCTURA SENNÆ ET JALAPÆ. *U. S.* TINCTURA SENNÆ COMPOSITA. *Ed.* *Tincture of Senna and Jalap.*

"Take of Senna *three ounces;* Jalap, in powder, *an ounce;* Coriander [seeds], bruised, Caraway [seeds], bruised, each, *half an ounce;* Cardamom [seeds], bruised, *two drachms;* Sugar [refined] *four ounces;* Diluted Alcohol *three pints.* Macerate for fourteen days, express, and filter through paper.

"This Tincture may also be prepared by beating well together the Senna, Jalap, Sugar, and Aromatics, moistening them thoroughly with Diluted Alcohol, allowing them to stand for forty-eight hours, then transferring them to a percolator, and gradually pouring upon them Diluted Alcohol until three pints of filtered liquor are obtained." *U. S.*

"Take of Sugar *two ounces and a half;* Coriander, bruised, *one ounce;* Jalap, in moderately fine powder, *six drachms;* Senna *four ounces*; Caraway, bruised, and Cardamom seeds, bruised, of each, *five drachms;* Raisins, bruised, *four ounces;* Proof Spirit *two pints* [Imperial measure]. Digest for seven days, strain the liquor, express strongly the residuum, and filter the liquids. This Tincture may be more conveniently and expeditiously prepared by percolation, as directed for the Compound Tincture of Cardamom." *Ed.*

This is another form of the *elixir salutis*, and scarcely differs from the preceding in virtues. It is given for the same purposes, and in the same doses. W.

TINCTURA SERPENTARIÆ. *U. S.*, *Lond.*, *Ed.* *Tincture of Virginia Snakeroot.*

"Take of Virginia Snakeroot, bruised, *three ounces;* Diluted Alcohol *two pints.* Macerate for fourteen days, express, and filter through paper.

"This Tincture may also be prepared by thoroughly moistening the Virginia Snakeroot, in powder, with Diluted Alcohol, allowing it to stand for twenty-four hours; then transferring it to a percolator, and gradually pouring upon it Diluted Alcohol until two pints of filtered liquor are obtained." *U. S.*

The *London College* takes *three ounces and a half* of the root, and *two Imperial pints* of proof spirit, and macerates for seven days; the *Edinburgh*, *three ounces and a half* of the root, in moderately fine powder, *a drachm* of bruised cochineal, and *two Imperial pints* of proof spirit, and proceeds either by percolation or digestion as for the tincture of Peruvian bark.

This tincture possesses the tonic and cordial properties of the root, and may be advantageously added to the infusion of Peruvian bark in low states of the system. The dose is one or two fluidrachms. W.

TINCTURA STRAMONII. *U. S.*, *Dub.* *Tincture of Stramonium.*

"Take of Stramonium Seed, bruised, *four ounces;* Diluted Alcohol *two pints.* Macerate for fourteen days, express, and filter through paper.

"This Tincture may also be prepared by thoroughly moistening the Stramonium Seed, in powder, with Diluted Alcohol, allowing it to stand for forty-eight hours, then transferring it to a percolator, and gradually pouring upon it Diluted Alcohol until two pints of filtered liquor are obtained." *U. S.*

The *Dublin College* takes *five avoirdupois ounces* of the bruised seeds, and *two Imperial pints* of proof spirit, and macerates for fourteen days.

This tincture may be used for all the purposes for which stramonium is given, in the dose of from ten to twenty minims (twenty to forty drops), repeated twice or thrice a day, and gradually increased till it obviously affects the system. W.

TINCTURA TOLUTANA. *U. S., Lond., Ed., Dub. Tincture of Tolu.*

"Take of Balsam of Tolu *three ounces;* Alcohol *two pints.* Macerate until the Balsam is dissolved; then filter through paper." *U. S.*

The *London College* employs *two ounces* of the balsam to *two Imperial pints* of rectified spirit; the *Edinburgh, three ounces and a half* of the balsam to *two Imperial pints* of rectified spirit; the *Dublin, two avoirdupois ounces* to *an Imperial pint.* The last mentioned College directs the balsam to be dissolved with the aid of a gentle heat, the solution to stand for subsidence, and the clear tincture to be decanted.

The tincture of tolu has the properties of the balsam, and may be employed as an addition to expectorant mixtures in chronic catarrhal affections; but the proportion of alcohol is too large to allow of its advantageous use in ordinary cases. The dose is one or two fluidrachms. In smaller quantities it is often employed to flavour cough mixtures. It is decomposed by water.

Off. Prep. Syrupus Tolutanus; Trochisci Lactucarii; Trochisci Morphiæ; Trochisci Morphiæ et Ipecacuanhæ; Trochisci Opii. W.

TINCTURA VALERIANÆ. *U. S., Lond., Ed., Dub. Tincture of Valerian.*

"Take of Valerian, bruised, *four ounces;* Diluted Alcohol *two pints.* Macerate for fourteen days, express, and filter through paper.

"This Tincture may also be prepared by thoroughly moistening the Valerian, in powder, with Diluted Alcohol, allowing it to stand for twenty-four hours, then transferring it to a percolator, and gradually pouring upon it Diluted Alcohol until two pints of filtered liquor are obtained." *U. S.*

The *London College* takes *five ounces* of bruised valerian, and *two Imperial pints* of proof spirit, and macerates for seven days; the *Dublin, five avoirdupois ounces* of the powdered root, and *two Imperial pints* of proof spirit, and macerates for fourteen days; the *Edinburgh, five ounces* of the former and *two Imperial pints* of the latter, and proceeds by percolation or digestion as for the tincture of Peruvian bark.

This tincture possesses the properties of valerian, but cannot be given in ordinary cases, so as to produce the full effects of the root, without stimulating too highly in consequence of the large proportion of spirit. The dose is from one to four fluidrachms. W.

TINCTURA VALERIANÆ AMMONIATA. *U. S., Ed.* TINCTURA VALERIANÆ COMPOSITA. *Lond. Ammoniated Tincture of Valerian.*

"Take of Valerian, bruised, *four ounces;* Aromatic Spirit of Ammonia *two pints.* Macerate for fourteen days, express, and filter through paper.

"This Tincture may also be prepared by thoroughly moistening the Valerian, in powder, with Aromatic Spirit of Ammonia, allowing it to stand for twenty-four hours in a covered vessel, then transferring it to a percolator, and gradually pouring upon it Aromatic Spirit of Ammonia until two pints of filtered liquor are obtained." *U. S.*

The *London College* takes *five ounces* of bruised valerian, and *two Imperial pints* of aromatic spirit of ammonia, and macerates for seven days; the *Edinburgh, five ounces* of valerian, and *two Imperial pints* of spirit of ammonia, and proceeds either by percolation, or by digestion in a well closed vessel, as directed for tincture of Peruvian bark.

The ammonia in this preparation is thought to assist the solvent powers of the alcohol, while it co-operates with the valerian in medical action. The tincture is employed as an antispasmodic in hysteria and other nervous affections.

The dose is one or two fluidrachms, and should be given in sweetened water, milk, or some mucilaginous fluid. W.

TINCTURA ZINGIBERIS. *U.S., Lond., Ed., Dub. Tincture of Ginger.*

"Take of Ginger, bruised, *eight ounces;* Alcohol *two pints.* Macerate for fourteen days, express, and filter through paper.

"This Tincture may also be prepared by thoroughly moistening the Ginger, in powder, with Diluted Alcohol, allowing it to stand for twenty-four hours, then transferring it to a percolator, and gradually pouring upon it Diluted Alcohol until two pints of filtered liquor are obtained." *U. S.*

The *London College* takes *two ounces and a half* of sliced ginger, and *two Imperial pints* of rectified spirit, and macerates for seven days; the *Dublin, eight avoirdupois ounces* of coarsely powdered ginger, and *two Imperial pints* of rectified spirit, and macerates for fourteen days; the *Edinburgh, two ounces and a half* of coarsely powdered ginger, and *two Imperial pints* of rectified spirit, and proceeds either by percolation or digestion, as for tincture of Peruvian bark.

The tinctures of the London and Edinburgh Colleges are too weak with ginger to be used advantageously for any other purpose than merely to impart flavour. We greatly prefer the processes of the U.S. and Dublin Pharmacopœias, which yield preparations in which the virtues of the ginger are not completely swallowed up in the menstruum. In consequence of the mucilaginous matter contained in ginger, the tincture made with diluted alcohol, or proof spirit, is apt to be turbid. Alcohol or rectified spirit is, therefore, properly preferred. We presume that the diluted alcohol directed in the U.S. process by percolation has been inadvertently put for alcohol, as the latter is directed in the first formula. Good Jamaica ginger should be used.

The tincture of ginger is a useful carminative, and may often be beneficially added to tonic and purgative infusions or mixtures, in debilitated states of the alimentary canal. It is, however, in this country, chiefly used for the preparation of syrup of ginger, for which purpose it is necessary to employ the strong tincture of the U.S. Pharmacopœia.

TROCHISCI.

Troches.

Troches or *lozenges* are small, dry, solid masses, usually of a flattened shape, consisting for the most part of powders incorporated with sugar and mucilage. They are designed to be held in the mouth, and dissolved slowly in the saliva, and are, therefore, adapted for the administration of those medicines only which do not require to be given in very large quantities, and are destitute of any very disagreeable flavour. They are much more used, and more skillfully prepared, in Europe than in this country. Tragacanth, from the greater tenacity of its mucilage, is better suited for their formation than gum Arabic. The following directions for preparing them are taken from the *Dictionnaire des Drogues.* A mucilage of tragacanth is first prepared with cold water and strained. With this the powders, including sugar, are thoroughly mixed by rubbing upon a marble slab, and are thus formed into a paste, which is spread out by means of a roller upon the surface of the marble, previously powdered over with a mixture of sugar and starch. The thickness of the extended mass is rendered uniform by a frame upon which the ends of the roller are placed. The upper surface is now covered with a thin layer of sugar and starch, and the mass is

divided into small cakes of a particular shape by means of a punch. These cakes are placed upon paper, and, having been exposed to the air for twelve hours, are carried into a drying room moderately heated. When perfectly dry they are thrown upon a sieve to separate the sugar and starch, and are then enclosed in bottles. In this way lozenges may be prepared from almost any medicine which the physician may deem it advisable to administer in that form. The following formula will serve as a guide. Take of citric acid, in powder, a drachm; refined sugar eight ounces; oil of lemons twelve minims; mucilage of tragacanth a sufficient quantity. Form them in the manner above directed into troches of twelve grains each. A species of lozenge is made by uniting the aromatic essential oils with sugar alone; but their preparation belongs to the confectioner rather than to the apothecary. The London and Dublin Pharmacopœias have omitted troches altogether. W.

TROCHISCI ACACIÆ. *Ed.* *Troches of Gum Arabic.*

"Take of Gum Arabic *four ounces;* Starch *one ounce;* Pure Sugar *one pound.* Mix and pulverize them, and make them into a proper mass with rose-water for forming lozenges." *Ed.*

These are useful in allaying the irritation of the fauces which excites coughing, and may be employed at pleasure. W.

TROCHISCI ACIDI TARTARICI. *Ed.* *Troches of Tartaric Acid.*

"Take of Tartaric Acid *two drachms;* Pure Sugar *eight ounces;* Volatile Oil of Lemons *ten minims.* Pulverize the Sugar and Acid, add the Oil, mix them thoroughly, and with Mucilage beat them into a proper mass for making lozenges." *Ed.*

These may be used as an agreeable refrigerant and demulcent in slight colds and fevers; but in large quantities are apt to derange the stomach. W.

TROCHISCI CRETÆ. *U. S., Ed.* *Troches of Chalk.*

"Take of Prepared Chalk *four ounces;* Gum Arabic, in powder, *an ounce;* Nutmeg, in powder, *a drachm;* Sugar, in powder, *six ounces.* Rub them together until they are intimately mixed; then with water form them into a mass, to be divided into Troches, each weighing ten grains." *U. S.*

The *Edinburgh College* uses the same ingredients in the same proportions, and beats them with a little water into a proper mass for making lozenges.

These are used as a gently astringent antacid in diarrhœa. W.

TROCHISCI GLYCYRRHIZÆ. *Ed.* *Troches of Liquorice.*

"Take of Extract of Liquorice [Liquorice, U. S.], and Gum Arabic, of each, *six ounces;* Pure Sugar *one pound.* Dissolve them in a sufficiency of boiling water; and then concentrate the solution over the vapour-bath to a proper consistence for making lozenges." *Ed.*

These lozenges are useful in allaying cough, but have been superseded in great measure by refined liquorice. W.

TROCHISCI GLYCYRRHIZÆ ET OPII. *U. S.* TROCHISCI OPII. *Ed.* *Troches of Liquorice and Opium.*

"Take of Opium, in powder, *half an ounce;* Liquorice, in powder, Sugar, in powder, Gum Arabic, in powder, each, *ten ounces;* Oil of Anise *a fluidrachm.* Mix the powders intimately; then add the Oil of Anise, and with water form them into a mass, to be divided into Troches, each weighing six grains." *U. S.*

"Take of Opium *two drachms;* Tincture of Tolu *half an ounce;* Pure Sugar, in fine powder, *six ounces;* Powder of Gum Arabic, and Extract of Liquorice [Liquorice, U. S.], of each, *five ounces.* Reduce the Opium to a fluid extract

by formula [*page* 983 U.S. Dispensatory]; mix it intimately with the Liquorice previously reduced to the consistence of treacle; add the Tincture; sprinkle the Gum and Sugar into the mixture, and beat it into a proper mass, which is to be divided into lozenges of ten grains." *Ed.*

The U. S. formula is more easy of execution than the Edinburgh, and affords a product probably not inferior. A preparation equivalent to the above is much used in Philadelphia under the name of *Wistar's cough lozenges.* Sometimes sulphate of morphia is substituted in equivalent proportion for the opium, and occasionally a little tartar emetic is added; but these modifications of the officinal formula are not admissible without a change of title.

These troches are demulcent and anodyne, and useful in allaying cough, when the case admits the employment of opium, of which each of them, prepared according to the U. S. formula, contains about one-tenth of a grain. W.

TROCHISCI IPECACUANHÆ. *U. S.* *Troches of Ipecacuanha.*

"Take of Ipecacuanha, in powder, *half an ounce;* Sugar, in powder, *fourteen ounces;* Arrow-root, in powder, *four ounces;* Mucilage of Tragacanth *a sufficient quantity.* Mix the powders intimately, and with the Mucilage form them into a mass, to be divided into Troches, each weighing ten grains." *U. S.*

These are useful expectorant lozenges in catarrhal complaints. Each of them contains about one-quarter of a grain of ipecacuanha. W.

TROCHISCI LACTUCARII. *Ed.* *Troches of Lactucarium.*

"To be prepared with Lactucarium in the same proportion and in the same manner as the Opium Lozenge." *Ed.*

This is a very feeble preparation; each lozenge containing only between the fifth and sixth of a grain of lactucarium. W.

TROCHISCI MAGNESIÆ. *U. S., Ed.* *Troches of Magnesia.*

"Take of Magnesia *four ounces;* Sugar *a pound;* Nutmeg, in powder, *a drachm;* Mucilage of Tragacanth *a sufficient quantity.* Rub the Magnesia, Sugar, and Nutmeg together until they are thoroughly mixed; then with the Mucilage form them into a mass, to be divided into Troches, each weighing ten grains." *U. S.*

"Take of Carbonate of Magnesia *six ounces;* Pure Sugar *three ounces;* Nutmeg *one scruple.* Pulverize them, and with Mucilage of Tragacanth beat them into a proper mass for making lozenges." *Ed.*

These are useful in acidity of stomach, especially when attended with constipation. W.

TROCHISCI MENTHÆ PIPERITÆ. *U. S.* *Troches of Peppermint.*

"Take of Oil of Peppermint *a fluidrachm;* Sugar, in powder, *a pound;* Mucilage of Tragacanth *a sufficient quantity.* Rub the Oil of Peppermint with the Sugar until they are thoroughly mixed; then with the Mucilage form them into a mass, to be divided into Troches, each weighing ten grains." *U. S.*

Useful in slight gastric or intestinal pains, nausea, and flatulence; but employed more for their agreeable flavour than for their medicinal effects. W.

TROCHISCI MORPHIÆ. *Ed.* *Troches of Morphia.*

"Take of Muriate of Morphia *one scruple;* Tincture of Tolu *half an ounce;* Pure Sugar *twenty-five ounces.* Dissolve the Muriate of Morphia in a little hot water; mix it and the Tincture of Tolu with the Sugar; and with a sufficiency of Mucilage form a proper mass for making lozenges, each of which should weigh about fifteen grains." *Ed.*

Useful for alleviating cough, and for other purposes which are answered by minute doses of morphia, of the muriate of which each lozenge contains about one-fortieth of a grain. W.

TROCHISCI MORPHIÆ ET IPECACUANHÆ. *Ed.* *Troches of Morphia and Ipecacuanha.*

"Take of Muriate of Morphia *one scruple;* Ipecacuan, in fine powder, *one drachm;* Tincture of Tolu *half a fluidounce;* Pure Sugar *twenty-five ounces.* Dissolve the Muriate in a little hot water; mix it with the Tincture and the Ipecacuan and Sugar; and with a sufficiency of Mucilage beat the whole into a proper mass, which is to be divided into fifteen grain lozenges." *Ed.*

Expectorant and anodyne, useful especially in allaying cough. Each lozenge contains about one-fortieth of a grain of muriate of morphia, and three times as much ipecacuanha. W.

TROCHISCI SODÆ BICARBONATIS. *U.S.*, *Ed.* *Troches of Bicarbonate of Soda.*

"Take of Bicarbonate of Soda *four ounces;* Sugar, in powder, *a pound;* Mucilage of Tragacanth *a sufficient quantity.* Rub the Bicarbonate of Soda with the Sugar until they are thoroughly mixed; then with the Mucilage form them into a mass, to be divided into Troches, each weighing ten grains." *U. S.*

"Take of Bicarbonate of Soda *one ounce;* Pure Sugar *three ounces;* Gum Arabic *half an ounce.* Pulverize them, and with mucilage beat them into a proper mass for making lozenges." *Ed.*

Antacid and antilithic, useful in heartburn and uric acid gravel. W.

UNGUENTA.

Ointments.

These are fatty substances, softer than cerates, of a consistence resembling that of butter, and such that they may be readily applied to the skin by inunction. When ointments are prepared by merely mixing medicinal substances with simple ointment or *lard*, care should be taken, if the added substance be a powder, that it be brought to the finest possible state of division, before being incorporated with the unctuous matter. If soluble in water or alcohol, it may often be advantageously rubbed with a little of one of these liquids. Gritty matter should not be allowed to enter these preparations. When an extract is added, if not uniformly soft, it should be made so by trituration with a little water or alcohol according to its nature. Many of the ointments become rancid if long kept, and should, therefore, be prepared in small quantities at a time, or only when wanted for use. The tendency to rancidity may be in a considerable degree counteracted by imbuing the unctuous vehicle with benzoin, or with poplar buds, as recommended by M. Deschamps (see *Am. Journ. of Pharm.*, xv. 260); but care should be taken that there be no therapeutical objection to the admixture. Slippery elm bark is said to have the same effect. (See *page* 741.) According to Dr. Geisler, ten drops of spirit of nitric ether, incorporated with an ounce of ointment, obviates the disagreeable fatty odour of these preparations. (*Pharm. Cent. Blatt*, A.D. 1847, p. 927, from *Arch. der Pharm.*) W.

ADEPS SUILLUS PRÆPARATUS. *Dub.* *Prepared Lard.*

"Take of Lard of Commerce *any convenient quantity.* Melt it in twice its weight of boiling water, stirring the mixture constantly; then set the mixture aside to cool, and separate the Lard when it has solidified." *Dub.*

Perfectly fresh lard is so readily obtainable in our markets that this process is unnecessary with us; but the apothecary cannot be too much upon his guard, in preparing the ointments, to have the lard entirely free from salt and rancidity. W.

UNGUENTUM ANTIMONII. *U. S.* UNGUENTUM ANTIMONIALE. *Ed.* UNGUENTUM ANTIMONII POTASSIO-TARTRATIS. *Lond.* UNGUENTUM ANTIMONII TARTARIZATI. *Dub.* *Antimonial Ointment. Tartar Emetic Ointment.*

"Take of Tartrate of Antimony and Potassa, in very fine powder, *two drachms;* Lard *an ounce.* Rub the Tartrate of Antimony and Potassa with a little of the Lard, then add the remainder, and mix them." *U. S.*

The *London* and *Edinburgh Colleges* mix *an ounce* of tartar emetic and *four ounces* of lard; the *Dublin, a drachm* of the former, and *seven drachms* of the ointment of white wax.

This may be most conveniently prepared with *simple ointment,* as lard is too soft to be spread on linen, and simple ointment is sufficiently so to be applied by inunction.

The peculiar eruptive effects of tartar emetic may be procured in various ways, by means either of a strong solution, or of the powder sprinkled upon the surface of some adhesive plaster, or of the ointment as above directed. The last method is, perhaps, the most convenient, and most generally resorted to. The proportion of tartar emetic may vary from one drachm with the ounce of lard, to two drachms, as in the U. S. officinal formula, or even to three drachms when a speedy effect is required, or the skin is not very susceptible to its action. A small portion of the ointment may be rubbed twice a day, or more frequently, upon the surface to be affected, or it may be applied spread upon a piece of linen. Care should be taken that the cuticle be entire, and that the application be not too long continued; as otherwise very severe inflammation, and even gangrenous ulceration, may result. We have, however, in some instances of great urgency, applied the ointment to a surface recently scarified in the operation of cupping; but, under such circumstances, it should be used with much caution. W.

UNGUENTUM AQUÆ ROSÆ. *U.S.* *Ointment of Rose Water.*

"Take of Rose Water *a fluidounce;* Oil of Almonds *two fluidounces;* Spermaceti *half an ounce;* White Wax *a drachm.* Melt together, by means of a water-bath, the Oil, Spermaceti, and Wax; then add the Rose Water and stir the mixture constantly until it is cold." *U. S.*

This preparation is much employed under the name of *cold cream.* It is a white, very soft, and elegant unguent, deriving a grateful odour from the rose water, which remains incorporated with the other constituents if kept enclosed in glazed vessels. It is a pleasant, cooling application to irritated and excoriated surfaces; and may be used with great advantage for chapped lips and hands, so frequent in cold weather. As the ointment is liable to become rancid when long kept, and the water to separate upon exposure, Mr. Joseph Laidley has proposed the substitution for the rose water of oil of roses and glycerin, the former in the proportion of two drops, the latter in that of four fluidrachms, the quantity of spermaceti being increased by two drachms. (*Am. Journ. of Pharm.*, xii. 119.) For some purposes the substitution is useful; but the officinal preparation is preferable for chapped hands, as the glycerin, not being absorbed, leaves an unpleasant sensation of stickiness on the skin. W.

UNGUENTUM BELLADONNÆ. *U.S., Lond.* *Ointment of Belladonna.*

"Take of Extract of Belladonna *a drachm;* Lard *an ounce.* Mix them." *U. S.*

The *London* formula is the same.

This is a convenient form for the external application of the extract of belladonna. Care must be taken in preparing it that the extract employed have the proper consistence; and, if dry and lumpy, it may be restored to the proper state by rubbing it with a little water in a heated mortar. W.

UNGUENTUM CANTHARIDIS. *U. S., Lond., Dub.* UNGUENTUM INFUSI CANTHARIDIS. *Ed.* *Ointment of Spanish Flies.*

"Take of Spanish Flies, in powder, *two ounces;* Distilled Water *half a pint;* Resin Cerate *eight ounces.* Boil down the Water with the Spanish Flies to one-half, and strain; then mix the Cerate with the strained liquor, and evaporate to the proper consistence." *U. S.*

The *London College* takes *three ounces* of the flies, in very fine powder, *twelve fluidounces* of distilled water, and *a pound* of resin cerate, and proceeds as above.

"Take of Cantharides, in moderately fine powder, Resin, and Bees'-wax, of each *one ounce;* Venice Turpentine, and Axunge [lard], of each, *two ounces;* boiling Water *five fluidounces.* Infuse the Cantharides in the Water for one night, squeeze strongly, and filter the expressed liquid. Add the Axunge, and boil till the water is dispersed. Then add the Wax and Resin; and when these have become liquid, remove the vessel from the fire, add the Turpentine, and mix the whole thoroughly." *Ed.*

"Take of Liniment of Spanish Flies *eight fluidounces;* White Wax *three ounces* [avoirdupois]; Spermaceti *one ounce* [avoird.]. Melt the Wax and Spermaceti in the Oil, with a gentle heat, and stir the mixture constantly until it concretes." *Dub.*

By these processes, the active matter of the flies is more uniformly diffused through the ointment than when they are directly incorporated, in the state of powder, with the other ingredients. The preparation is thus better calculated to meet the end proposed of maintaining the discharge from blistered surfaces, without producing undue irritation. It has been said that the virtues of the flies are impaired by boiling; but the contrary has been proved by experiment to be the case; the cantharidin being neither altered nor volatilized at the boiling temperature. (See *Cantharis.*) The Edinburgh College, therefore, gains nothing by the substitution of infusion. It is necessary, in the U. S. and London processes, after the strained decoction and cerate have been mixed, to stir constantly during the continuance of the evaporation, in order to prevent the former from sinking to the bottom. Unless with care a considerable portion of the decoction will be retained by the flies when strained, and thus loss be incurred. To prevent this, pour the concentrated decoction into a glass funnel with some cotton twist in its mouth, and, when the liquid ceases to pass, pour in water gradually and carefully until four fluidounces of the filtered decoction are obtained; then proceed to incorporate this with the cerate as directed. The Dublin preparation is more elegant than the others, the liniment ordered being an oleaginous solution of the active matter of the flies, and easily mixing with the other ingredients. It should be recollected that this ointment is intended as a dressing for blisters, not to produce vesication. The Edinburgh ointment differs from the others in containing Venice turpentine, which renders it more stimulating. *Dupuytren's ointment* employed as a local application to prevent the loss of hair, was made by macerating a drachm of flies in a fluidounce of alcohol, and incorporating one part of the tincture thus formed with nine parts of lard. W.

UNGUENTUM CANTHARIDIS. *Ed.* CERATUM CANTHARIDIS. *Lond.* *Ointment of the Powder of Spanish Flies.*

"Take of Resinous Ointment *seven ounces;* Cantharides, in very fine powder, *one ounce.* Melt the Ointment; sprinkle into it the Cantharides powder, and stir the mixture briskly as it concretes on cooling." *Ed.*

"Take of Spanish Flies, in very fine powder, *an ounce;* Spermaceti Cerate *six ounces.* To the Cerate softened by heat, add the Flies, and mix." *Lond.*

This ointment, like the preceding, is intended as a dressing for blistered surfaces, with a view to maintain the discharge. The flies should be very finely

powdered, in order that they may be diffused as uniformly as possible through the mass. It is unfortunate that the term *ceratum cantharidis* has been conferred upon this preparation by the London College; as the same name is properly applied in the U. S. Pharmacopœia to the preparation of flies intended to be used as a vesicatory. Neither of these ointments can be used in individuals liable to strangury from the external application of cantharides. W.

UNGUENTUM CETACEI. *Lond.* *Spermaceti Ointment.*

"Take of Spermaceti *five ounces;* White Wax *fourteen drachms;* Olive Oil *a pint* [Imperial measure], or *a sufficient quantity.* Melt them together over a slow fire, and stir them constantly until cold." *Lond.*

This ointment is employed as a mild dressing for blisters, wounds, and excoriated surfaces. It should be made in small quantities at a time, as it is apt to become rancid when long kept. W.

UNGUENTUM COCCULI. *Ed.* *Ointment of Cocculus Indicus.*

"Take *any convenient quantity* of Cocculus Indicus, separate and preserve the kernels, beat them well in a mortar, first alone and then with a little Axunge [lard]; and then add Axunge till it amounts altogether to five times the weight of the kernels." *Ed.*

This ointment is used for the destruction of Vermin, and in the cure of scabies and ringworm of the scalp. In the latter complaint it was found very useful by the late Dr. Hamilton, sen., of Edinburgh. W.

UNGUENTUM CONII. *Lond.* *Ointment of Hemlock.*

"Take of fresh Hemlock [Leaves], Lard, each, *a pound.* Boil the Hemlock in the Lard till it becomes crisp, then express through linen." *Lond.*

This ointment has been used as an anodyne application to irritable piles, painful glandular swellings and scirrhous tumours, and to cancerous and other painful ulcers; but the virtues of the hemlock are impaired by the heat necessary in its preparation. An ointment made by mixing good extract of hemlock with lard would be more efficient. W.

UNGUENTUM CREASOTI. *U. S., Lond., Ed., Dub.* *Ointment of Creasote.*

"Take of Creasote *half a fluidrachm;* Lard *an ounce.* Mix them." *U. S.*

The *London* process is the same as that of the U. S. Pharmacopœia. The *Edinburgh College* takes *a drachm* of creasote and *three ounces* of lard, melts the lard, adds the creasote, and stirs briskly till the mixture concretes on cooling. The *Dublin College* takes a fluidrachm of creasote and *seven drachms* (Dub. weight) of ointment of white wax (simple ointment), and proceeds in the same manner as the Edinburgh.

For the use of this ointment see *Creasotum.* It may sometimes be advantageously diluted with lard when found to irritate. W.

UNGUENTUM CUPRI SUBACETATIS. *U. S., Dub.* UNGUENTUM ÆRUGINIS. *Ed.* *Ointment of Subacetate of Copper.*

"Take of Subacetate of Copper, in fine powder, *a drachm;* Simple Ointment *fifteen drachms.* Add the Subacetate of Copper to the Ointment previously melted with a moderate heat, and stir them constantly till they are cold." *U. S.*

"Take of Resinous Ointment *fifteen ounces;* Verdigris, in fine powder, *one ounce.* Melt the Ointment, sprinkle into it the powder of Verdigris, and stir the mixture briskly as it cools and concretes." *Ed.*

"Take of Prepared Subacetate of Copper *half a drachm;* Ointment of White Wax [Unguentum Simplex, *U. S.*] *seven drachms and a half.* Triturate the Subacetate of Copper with the Ointment until they are intimately mixed." *Dub.*

This ointment is employed as a mild escharotic in fungous granulations, and,

more or less diluted with lard, as a stimulating application to foul and flabby ulcers, scrofulous ulcerations of the edges of the eyelids, disease of the external meatus of the ear with purulent discharge, to warts and corns, and to certain cutaneous eruptions, particularly that form of porrigo denominated *ringworm of the scalp.* W.

UNGUENTUM ELEMI. *Lond., Dub. Ointment of Elemi.*

"Take of Elemi *three ounces;* Turpentine *two ounces and a half;* Suet *six ounces;* Olive Oil *half a fluidounce.* Melt the Elemi with the Suet, and, having removed them from the fire, immediately mix them with the Turpentine and Oil, and express through linen." *Lond.*

"Take of Resin of Elemi *four ounces* [avoirdupois]; Ointment of White Wax *one pound* [avoirdupois]. Melt them together, strain through flannel, and stir the mixture constantly till it concretes." *Dub.*

This ointment is applied as a gentle stimulant to weak ulcers, and may be used for maintaining the discharge of issues and setons. It is the *linimentum arcæi* of the older pharmacy. W.

UNGUENTUM GALLÆ. *U.S., Dub. Ointment of Galls.*

"Take of Galls, in powder, *an ounce;* Lard *seven ounces.* Mix them." *U. S.*

The *Dublin College* rubs *a drachm* of galls, in very fine powder, with *seven drachms* of ointment of white wax.

This is used chiefly in piles and prolapsus ani, though it may also be advantageously applied to flabby and indolent ulcers. W.

UNGUENTUM GALLÆ COMPOSITUM. *Lond.* UNGUENTUM GALLÆ ET OPII. *Ed. Compound Ointment of Galls.*

"Take of Galls, in very fine powder, *six drachms;* Lard *six ounces;* Opium, in powder, *a drachm and a half.* Rub them together." *Lond.*

The *Edinburgh College* takes *two drachms* of galls, *a drachm* of opium, and *an ounce* of lard, and rubs them together into a uniform mass.

This combination of galls and opium is sometimes employed, preferably to the simple ointment of galls, in cases of irritable piles. From half a drachm to a drachm of camphor is sometimes added to the London ointment. W.

UNGUENTUM HYDRARGYRI. *U.S., Lond., Ed., Dub. Mercurial Ointment.*

"Take of Mercury *two pounds;* Lard *twenty-three ounces;* Suet *an ounce.* Rub the Mercury with the Suet and a small portion of the Lard until the globules disappear; then add the remainder of the Lard, and mix." *U. S.*

The *London* process is the same, with one-half of the quantity of material.

"Take of Mercury *two pounds;* Axunge [lard] *twenty-three ounces;* Suet *one ounce.* Triturate the Mercury with the Suet and a little of the Axunge till globules are no longer visible; then add the rest of the Axunge, and mix the whole thoroughly. This ointment is not well prepared so long as metallic globules may be seen in it with a magnifier of four powers. The Mercurial Ointment with the proportions here directed may be diluted at pleasure with twice or thrice its weight of axunge." *Ed.*

"Take of Pure Mercury, Prepared Lard, of each, *a pound.* Rub them together until metallic globules cease to be visible to the naked eye." *Dub.*

The Pharmacopœias unite at present in recognising but one mercurial ointment, which contains equal weights of mercury and fatty matter. When the physician wishes a weaker preparation, he may direct the ointment to be diluted with such a proportion of lard as may answer his purposes. The Edinburgh College, in allowing dilution of the ointment in certain fixed proportions, should have given names, by which the weaker preparations might be designated.

In the preparation of mercurial ointment, care is requisite that the mercury should be completely extinguished. The trituration is best performed in a marble mortar, as it is difficult to keep iron so clean as not to impart more or less oxide to the ointment. The mercury is known to be extinguished, when a portion of the mass, rubbed upon paper or the back of the hand, exhibits no metallic globules under a magnifying glass of four powers. The operation cannot be considered as satisfactorily accomplished when the globules are invisible merely to the naked eye. To facilitate the process, which is very tedious, the addition of various substances has been proposed, calculated to hasten the disappearance of the metal. Turpentine and sulphur have been employed, but are inadmissible; the former because it renders the ointment too irritating, the latter because it forms with the mercury an inactive sulphuret. Their presence in the ointment may be detected by the peculiar odour which they respectively emit when exposed to heat. Sulphur, moreover, gives the ointment a darker colour than it has when pure. The addition of a little sulphuric ether, at intervals, during the trituration, is said greatly to abbreviate the process. (*Am. Journ. of Pharm.*, xvii. 80.) Rancidity in the lard employed facilitates the extinguishment of the mercury, but is liable to the same objection as turpentine, though in a much less degree. M. Fossembras found that the addition of rancid fat was required in the proportion of only ten drachms to a pound of the ointment, in order to enable eight pounds to be prepared in an hour. (*Journ. de Pharm.*, 3*e sér.*, v. 75.) M. Guibourt recommends the addition of one-sixteenth of old mercurial ointment. M. Simonin proposes the use of lard which has been exposed in thin layers to a damp air for fifteen days. This facilitates the extinguishment of the metal, but it probably renders the preparation more irritant by the chemical alteration of the lard. The following plan of preparing the ointment was proposed by M. Chevallier. A pound of mercury, and half a pound of fresh lard previously melted, are introduced into a stone or glass bottle, shaken till the mixture acquires the consistence of very thick syrup, then poured into a mortar, and incorporated by constant stirring with an additional half pound of lard. In this manner, according to Chevallier, a perfect ointment may be made in half an hour. When prepared with lard alone, the ointment is apt, in hot weather, to become so soft as to allow the metal to separate. Hence the addition of suet in the processes of the U. S., London, and Edinburgh Pharmacopœias; and even a larger proportion might be employed when the ointment is prepared for use in the summer season.

Upon the whole, it may be considered doubtful whether any of the expedients for saving labour and time in the preparation of the ointment are wholly unobjectionable. Dr. Christison states that the better plan is not to complete the process by a continuous trituration, but to operate for a short time every day, and allow the ointment in the mean time to be exposed to the air. But so much labour is required in the process, that the ointment is preferably made by machinery on the large scale. The fatty matters, kept in the fluid state by a heat of about 100°, are triturated with the metal by means of two iron balls, which are driven rapidly round in a circular iron trough by steam power. The extinguishment of the mercury is thus effected in about twelve hours.

A new method of preparing mercurial ointment, proposed by Orosi, is to precipitate metallic mercury, in the pulverulent form, from a solution of corrosive sublimate, by an excess of protochloride of tin, with the addition of muriatic acid; and, having poured off the supernatant fluid, washed the precipitate with warm water, and dried it between bibulous paper, to incorporate it with the prescribed proportion of lard. To prevent the precipitated mercury from running into globules, it is recommended to cover with fat the interior of the vessel in which the precipitation takes place. (*Ranking's Abstract*, i. 350.)

Mercurial ointment has when newly prepared a bluish colour, which becomes darker by age. It has been thought to contain the mercury in the state of protoxide; but most of the metal can be separated by methods not calculated to reduce the oxide; and it is now generally admitted that by far the greater part of it exists in a state of minute division, not of chemical combination. It has been shown, however, that the metal is slightly oxidized; and the change of colour which the ointment undergoes with age is attributable to further oxidation. If the ointment be kept long melted in a narrow vessel, metallic mercury subsides, and an oily liquid floats upon the surface. After this has been filtered so as to separate everything undissolved, it is blackened by sulphuretted hydrogen, and yields oxide of mercury to acetic acid. Dr. Christison states that he has examined various samples of the ointment, and never failed to detect oxide of mercury; and he has inferred from his observations, that the oxide amounts to rather more than one per cent. (*Christison's Dispensatory.*) But the proportion is variable according to the age and mode of preparation of the ointment. It scarcely admits of a doubt, that the oxide of mercury formed enters into chemical combination with the lard, or one of its oily acids. Mr. Donovan advanced the idea that the medicinal activity of the ointment depended exclusively on this compound of the lard with the mercurial oxide. An ointment made by merely mixing lard and black oxide of mercury has not the same effect, because there is no chemical union between the ingredients. But, upon exposing such a mixture to a temperature of 350°, and continually agitating it for two hours, he found that every ounce of lard dissolved and combined with twenty-one grains of oxide, and the resulting compound was proved to be equally effectual with the common ointment, and capable of being introduced into the system in one-third of the time. It has been proposed to substitute an ointment thus prepared for that made according to the officinal directions, as being more manageable, and of more uniform strength. Care, however, would be required in preparing it to avoid a temperature either too high or too low; as the former might decompose the oxide, and the latter would be insufficient to effect its union with the lard. There would be danger, also, that the lard might be rendered irritant by the influence of the heat. Dr. F. Von Bærensprung has rendered it extremely probable that metallic mercury, no matter in what state of division it may be, is unable to enter the blood-vessels, and that whatever effects on the system are produced by the ointment, or any similar preparation, or even by the vapours of mercury, are owing to the previous oxidation of the metal. (See *Chem. Gaz.*, Sept. 1, 1850, p. 321.)

From experiments by a committee of the College of Pharmacy, of New York, it appears that the ointment contained in jars becomes somewhat unequal in consequence of the settling of the metallic ingredient. The inference is that, after long standing, the contents of the jar should be triturated so as to restore an equable strength before being dispensed. (*Am. Journ. of Pharm.*, xvi. 2.)

Medical Uses. Mercurial ointment, when rubbed upon the surface of the body, produces, in consequence of its absorption, the general effects of mercury upon the system. It is resorted to either alone, when circumstances prevent or discourage the internal use of mercury, or conjointly with the internal use of the medicine, to produce a more speedy or powerful effect in urgent cases. It may also be advantageously employed as a resolvent in local affections; as in the case of venereal buboes, and of chronic glandular swellings, upon which it may be made to operate directly by being applied in the course of the absorbents passing through the enlarged glands. The proper quantity to be employed at one time, with a view to salivation, is about a drachm, which should be applied night and morning, by means of friction, to the inner surface of the thighs, legs, or arms, and continued till the system is affected.

In urgent cases, or in local affections, it may also be rubbed on other parts of the body, or applied to blistered surfaces. The friction should on each occasion be continued till the whole of the ointment is absorbed. When frequently rubbed upon the same part, it is apt to produce a disagreeable eruption which interferes with its continued application. Camphor is sometimes added, in order to render it more easy of absorption; but, without producing this effect, it increases the liability of the ointment to irritate the skin, and is of no other advantage than to soften its consistence when too firm from a large proportion of suet. Mercurial ointment has been employed, with some success, to prevent the maturation of the smallpox pustule, and the consequent pitting. For this purpose it may be applied to the face or other part, thickly spread on patent lint or muslin, care being taken to prevent the access of the air to the covered part. To be successful it must be applied before the third or fourth day of the eruption. The ointment has been recommended also in erysipelas and chilblains. Iodide of potassium rubbed with mercurial ointment is said to promote the separation of the mercury in the form of globules (*Journ. de Pharm.*, 3*e sér.*, x. 356); but the effect does not take place if the iodide is thoroughly dried and well powdered, and the ointment added to it by small portions at a time. (*Ibid.*, x. 421.)

The ointment diluted with twice or three times its weight of lard is sometimes employed as an application to ulcers, and to certain cutaneous eruptions.

Off. Prep. Ceratum Hydrargyri Comp.; Linimentum Hydrargyri. W.

UNGUENTUM HYDRARGYRI AMMONIATI. *U. S.* Unguentum Hydrargyri Ammonio-chloridi. *Lond.* Unguentum Precipitati Albi. *Ed.* *Ointment of Ammoniated Mercury. Ointment of White Precipitate.*

"Take of Ammoniated Mercury *a drachm;* Simple Ointment *an ounce and a half.* Mix them." *U. S.*

The processes of the *British Colleges* are essentially the same as the above.

This ointment is employed chiefly in cutaneous eruptions, such as psora, porrigo, and herpes. W.

UNGUENTUM HYDRARGYRI IODIDI. *Lond.* *Ointment of Iodide of Mercury.*

"Take of Iodide of Mercury *an ounce;* White Wax *two ounces;* Lard *six ounces.* To the Wax and Lard melted together add the Iodide, and rub together." *Lond.*

UNGUENTUM HYDRARGYRI IODIDI RUBRI. *Dub.* *Ointment of Red Iodide of Mercury.*

"Take of Red Iodide of Mercury *one drachm;* Ointment of White Wax *seven drachms.* Incorporate the Iodide of Mercury and Ointment by careful trituration in a mortar." *Dub.*

Both the above ointments are employed as dressings to scrofulous ulcers; the ointment of the red iodide being preferred, on account of its much greater activity, when the ulcers are very indolent. W.

UNGUENTUM HYDRARGYRI NITRATIS. *U. S.*, *Lond.* Unguentum Citrinum. *Ed.* Unguentum Hydrargyri Nitratis *vel* Unguentum Citrinum. *Dub.* *Ointment of Nitrate of Mercury. Citrine Ointment.*

"Take of Mercury *an ounce;* Nitric Acid *fourteen fluidrachms;** Fresh Neats-foot Oil *nine fluidounces;* Lard *three ounces.* Dissolve the Mercury in

* In the last edition of this work, the old quantity of *eleven* fluidrachms of nitric acid was inadvertently retained, instead of *fourteen*, as directed in the present U. S. Pharmacopœia, which, by adopting a weaker acid, rendered an increase of the quantity necessary.

the Acid; then heat together the Oil and Lard, in an earthen vessel, to 200°; lastly, add the mercurial solution, and stir with a wooden spatula constantly so long as effervescence continues, and afterwards occasionally until the ointment stiffens." *U. S.*

"Take of Mercury *two ounces;* Nitric Acid *four fluidounces* [Imperial measure]; Lard *a pound;* Olive Oil *eight fluidounces* [Imp. measure]. First dissolve the Mercury in the Acid; then, while the solution is hot, mix it with the Lard and Oil previously melted together." *Lond.*

"Take of Pure Nitric Acid *eight fluidounces and six fluidrachms* [Imperial measure]; Mercury *four ounces;* Axunge [lard] *fifteen ounces;* Olive Oil *thirty-two fluidounces.* Dissolve the Mercury in the Acid with the aid of a gentle heat. Melt the Axunge in the Oil with the aid of a moderate heat in a vessel capable of holding six times the quantity; and, while the mixture is hot, add the solution of mercury, also hot, and mix them thoroughly. If the mixture do not froth up, increase the heat a little till this take place. Keep this Ointment in earthenware vessels, or in glass vessels secluded from the light." *Ed.* Dr. Christison, in his Dispensatory, states that, in this formula, in order to meet the intentions of its framers, the quantity of Olive Oil should be *thirty-eight fluidounces and a half,* and of Nitric Acid (sp. gr. from 1·380 to 1·390) *nine fluidounces and a half.*

"Take of Pure Mercury *one ounce* [avoirdupois]; Pure Nitric Acid *one fluidounce;* Distilled Water *half a* [*fluid*] *ounce;* Prepared Lard *four ounces* [avoird.]; Olive Oil *eight fluidounces.* Mix the Acid with the Water, and dissolve the Mercury in the mixture, with the aid of a gentle heat. Melt the Lard with the Oil, and, while the mixture is hot, add to it the solution of mercury also hot; let the temperature of the mixture next be raised so as to cause effervescence, and then, withdrawing the heat, stir the mixture with a porcelain spoon, until it concretes on cooling." *Dub.*

The chemical changes which take place in the preparation of this ointment are not precisely known. They differ somewhat according to the circumstances under which the operation is performed; for example, according to the proportion and strength of the acid, the nature of the fatty matter, and the degree of heat employed. The mercury, in the first step of the process, is oxidized at the expense of a portion of the acid, nitrous fumes escape, and the undecomposed acid unites with the oxidized metal, forming binitrate of the deutoxide of mercury if heat be employed, and a mixture of this with nitrate of the protoxide, if the process be conducted at a low temperature. When the mercurial solution is added to the fatty matter, a reaction takes place, which probably results in the production of the yellow subnitrate of the deutoxide of mercury, of one or more of the fatty acids, as the oleic, margaric, and stearic, and of elaïdin or elaïdic acid, or both. (See *page* 495.) It is also highly probable that portions of these fatty acids combine with the oxide of mercury. But the degree to which these changes take place is influenced greatly by the temperature to which the mixture is exposed. If this be low, there is little or no escape of gas; if elevated, there is a copious evolution of nitrous fumes. In the former case the changes are obviously less considerable than in the latter.

As formerly prepared, this ointment, though at first beautifully yellow and of the proper consistence, soon began to change, acquiring in time a dirty greenish and mottled colour, and becoming so hard and friable as to be unfit for use unless mixed with lard. These results were ascribed to various causes, and as many different modifications of the process were proposed in order to obviate them. The U.S. process is based upon the fact, that the olive oil of the British processes is hardened by nitrous acid or the nitrate of mercury, while the same effect is not produced upon neats-foot oil. As at first published, the process was defective in the direction to add the mercurial solution to the

mixed oleaginous fluid when it begins to stiffen on cooling. When this direction was complied with, at least with the acid of the ordinary strength, the preparation had a brown colour and semi-liquid consistence; but, with some modifications such as have been introduced into the revised formula of the Pharmacopœia of 1850, the process yields an excellent ointment, which, though it sometimes assumes a greenish colour on exposure, retains permanently a soft unctuous consistence. We have had specimens of the ointment in our possession for several years, which have retained a uniform yellowish colour, and a perfectly good unctuous consistence. It is said that the three ounces of lard of this formula may be advantageously replaced by the same quantity of neats-foot oil. (*Am. Journ. of Pharm.*, iv. 197.) It is probable that other animal oils will answer the same purpose; and it is asserted that a good preparation may be made with lard or butter alone. The drying vegetable oils do not appear, like olive oil, to be converted by nitrous acid or the nitrate of mercury into elaïdin; and it was a fair inference that they might be employed advantageously in the preparation of citrine ointment. Accordingly, Dr. Fessenden, of North Carolina, states, in his inaugural essay, that he substituted linseed oil for the neats-foot oil of the U. S. process, and succeeded in obtaining a perfectly good and durable ointment. It is now stated that the failure of many operators who have followed the former British officinal processes, has been owing not so much to the character of the particular oil employed, as to deficiency of strength in the nitric acid, and the want of a due degree of heat. Mr. Alsop asserts that, if the nitric acid be of the sp. gr. 1·5, or if the quantity of a weaker acid be increased so as to compensate for its deficiency in strength, and if the fatty matters be mixed with the mercurial solution at an elevated temperature, a permanently soft and golden-coloured ointment will result. (*Pharm. Transactions*, Sept. 1841.) It is probable that the discoloration which is so apt to take place in the preparation is owing to the deoxidizing influence of the fatty matter upon the mercurial oxide. Now if, by a sufficient excess of acid and an elevated temperature, the fats be well oxidized during the process, they will have less affinity for oxygen afterwards, and consequently less ability to take it from the oxide of mercury. That they are oxidized at the expense of the nitric acid when heat is used, is proved by the abundant extrication of nitrous fumes during the operation.

But in applying heat, when the fatty matter and mercurial solution are mixed, care must be taken that it be not too great. Gas is extricated at 180°, and at 212°, escapes so abundantly that the mixture boils over unless the vessel be very large. (*Alsop.*) Besides, if the heat is too great, a portion of the mercury is reduced, and the colour of the ointment impaired. When large quantities of materials are operated upon, the reaction which occurs produces of itself a sufficient heat; but in ordinary cases the temperature should be kept at about 190° by means of a water-bath, and if it exceed 205° should be reduced. It should always be sufficient to produce a copious extrication of gas. The ointment should be prepared in a glass, porcelain, or well-glazed earthen vessel; and a glass rod or wooden spatula should be employed for stirring the mixture.

In the present U. S., Edinburgh, and Dublin formulæ, the provision in relation to the application of heat is incorporated; and either of them will yield a good ointment with due care in the manipulations. For some useful practical hints upon this point the reader is referred to a communication by Mr. Joseph Laidlaw in the *Am. Journ. of Pharm.* (xxii. 119). It is due to Mr. Duncan, a chemist and druggist of Edinburgh, to state that he appears to have been the first to ascertain the value of heat in the preparation of this ointment.

Medical Uses. This ointment is much and very advantageously employed, as

a stimulant and alterative application, in porrigo or tinea capitis, impetigo larvalis or crusta lactea, psoriasis and pityriasis, certain forms of chronic eczema, psorophthalmia and inflammation of the eye and eyelids connected with porrigo of the face or scalp, and various other ulcerative and eruptive affections. It should be diluted with lard, unless in cases which require a very stimulant application. Some care is requisite in its use, to avoid the risk of salivation. When hard and friable, it must be rubbed up with fresh lard before it can be applied.

An ointment prepared with lard and nitric acid, called *Alyon's* ointment, after the person who first prepared it, was formerly much used in cases similar to those in which the citrine ointment is now employed. The *ointment of nitric acid* of the former Edinburgh and Dublin Pharmacopœias, discarded in the last edition of those works, was of this character.

Off. Prep. Unguentum Hydrargyri Nitratis Mitius. W.

UNGUENTUM HYDRARGYRI NITRATIS MITIUS. *Lond.* *Milder Ointment of Nitrate of Mercury.*

"Take of Ointment of Nitrate of Mercury *an ounce;* Lard *seven ounces.* Rub them together." *Lond.*

This is a mere dilution of the citrine ointment, and might well have been left to extemporaneous prescription. The London College states that it should be used recently prepared. W.

UNGUENTUM HYDRARGYRI OXIDI RUBRI. *U. S.* Unguentum Hydrargyri Nitrico-oxidi. *Lond.* Unguentum Oxidi Hydrargyri. *Ed.* Unguentum Hydrargyri Oxydi Rubri. *Dub.* *Ointment of Red Oxide of Mercury.*

"Take of Red Oxide of Mercury, in very fine powder, *a drachm;* Simple Ointment *an ounce.* Add the Oxide of Mercury to the Ointment previously softened over a gentle fire, and mix them." *U. S.*

"Take of Nitrico-oxide of Mercury *an ounce;* White Wax *two ounces;* Lard *six ounces.* To the Wax and Lard, melted together, add the Nitrico-oxide, in very fine powder, and rub them together." *Lond.*

"Take of Red Oxide of Mercury *one ounce;* Axunge [lard] *eight ounces.* Triturate them into a uniform mass." *Ed.*

"Take of Red Oxide of mercury *one drachm;* Ointment of White Wax *seven drachms.* Reduce the Oxide to a very fine powder, and mix it intimately with the Ointment by trituration." *Dub.*

The red oxide of mercury here referred to is that prepared from the nitrate, and usually called *red precipitate.* It is highly important that the oxide should be thoroughly pulverized before being mixed with the lard; as otherwise it might prove very injurious in cases of ophthalmia, in which it is sometimes used.

This ointment loses its fine red colour when long kept, probably in consequence of the conversion of the red oxide into the black, or its reduction to the metallic state. It is best to prepare it only in small quantities at a time. We have been informed that, if the preparation be made by mixing the red oxide with poplar-bud ointment, it will keep a long time without change. According to R. H. Stabler, of Alexandria, Va., an equally effectual method is to mix two drops of liquor potassæ with each ounce of the ointment when prepared. (*Am. Journ. of Pharm.*, xxiii. 123.) It is a highly useful stimulating ointment, much employed in indolent and foul ulcers, in porrigo of the scalp, psorophthalmia, and chronic conjunctival ophthalmia, especially when attended with thickening of the inner membrane of the eyelids, or with specks upon the cornea. It may be diluted with lard if found too stimulating. W.

UNGUENTUM IODINII. *U. S. Ointment of Iodine.*

"Take of Iodine *a scruple;* Iodide of Potassium *four grains;* Water *six minims;* Lard *an ounce.* Rub the Iodine and Iodide first with the Water until liquefied, and then with the Lard until thoroughly mixed." *U. S.*

The object of the iodide of potassium and water is simply to bring the iodine into a state in which it may be thoroughly and equably incorporated with the lard. They have been found to answer better in practice than the alcohol formerly used.

This ointment, when rubbed upon the skin, imparts to it an orange colour, which, however, slowly disappears with the evaporation of the iodine. It is useful as a local application in goitre, scrofulous swellings of the glands, and other chronic tumefactions, operating probably through the medium of absorption. When continued for some time, it occasionally produces a pustular eruption upon the portion of skin to which it is applied. Dr. Cerchiari strongly recommends it in cases of enlarged tonsils, after the disappearance of inflammation. It should be applied to the tonsils morning and evening by means of a camel's hair pencil. In two months, according to the author, the enlargement disappears. (*Am. Journ. of Pharm.*, viii. 83.) The ointment should be prepared only as wanted for use; for it undergoes change if kept, losing its deep orange-brown colour, and becoming pale upon the surface. W.

UNGUENTUM IODINII COMPOSITUM. *U.S.*, *Lond.*, *Dub.* UNGUENTUM IODINEI. *Ed. Compound Ointment of Iodine.*

"Take of Iodine *half a drachm;* Iodide of Potassium *a drachm;* Alcohol *a fluidrachm;* Lard *two ounces.* Rub the Iodine and Iodide of Potassium first with the Alcohol and then with the Lard until they are thoroughly mixed." *U. S.*

The *London College* uses the same ingredients, in the same proportions; but directs that the iodide should be powdered as finely as possible, the iodine dissolved in the alcohol, and the two then rubbed together. The *Edinburgh College* directs *a drachm* of iodine and *two drachms* of the iodide of potassium to be rubbed together, *four ounces* of lard to be gradually added, and the trituration to be continued till a uniform ointment is obtained. The *Dublin College* rubs *half a drachm* of pure iodine and *a drachm* of iodide of potassium well together, adds gradually *fourteen drachms and a half* of simple ointment, and triturates till a uniform ointment is produced.

This preparation is employed for the same purposes as the preceding, from which it differs chiefly in being somewhat stronger with iodine; as the iodide of potassium is probably not peculiar in its effects, and the spirit is employed only to facilitate the admixture. W.

UNGUENTUM MEZEREI. *U.S. Ointment of Mezereon.*

"Take of Mezereon, sliced transversely, *four ounces;* Lard *fourteen ounces;* White Wax *two ounces.* Moisten the Mezereon with a little Alcohol, and beat it in an iron mortar until reduced to a fibrous mass; then digest it, by means of a salt-water bath, with the Lard and Wax previously melted together, for twelve hours; strain with strong expression, and allow the strained liquid to cool slowly, so that any undissolved matters may subside. From these separate the medicated ointment." *U. S.*

This is equivalent to the *pommade épispastique au garou* of the French Codex, which is prepared from the bark of *Daphne Gnidium.* The ointment may also be made, as proposed by Guibourt, by mixing two drachms of the alcoholic extract of mezereon with nine ounces of lard and one of wax. It is used as a stimulating application to blistered surfaces in order to maintain the discharge, and to obstinate, ill-conditioned, and indolent ulcers. W.

UNGUENTUM OPII. *Lond.* *Ointment of Opium.*

"Take of Opium, in powder, *a scruple;* Lard *an ounce.* Rub them together." *Lond.*

A form in which opium may be applied by inunction. W.

UNGUENTUM PICIS. *Lond.* *Ointment of Pitch.*

"Take of Pitch, Wax, Resin, each, *eleven ounces;* Olive Oil *a pint.* Melt them together, and express through linen." *Lond.*

This is the *ointment of black pitch* of the former London Pharmacopœia. It may be used for the same purposes as tar ointment, but is less efficient. W.

UNGUENTUM PICIS LIQUIDÆ. *U. S.*, *Lond.*, *Ed.*, *Dub.* *Tar Ointment.*

"Take of Tar, Suet, each, *a pound.* Add the Tar to the Suet previously melted with a moderate heat, and stir them constantly till they are cold." *U. S.*

The *London College* melts together *a pound*, each, of tar and suet, and strains through linen. The *Edinburgh College* takes *five ounces* of tar and *two ounces* of bees' wax, and, having melted the wax with a gentle heat, adds the tar, and stirs the mixture briskly while it concretes. The *Dublin College* melts *four avoirdupois ounces* of yellow wax, adds *half a pint* [Imperial measure] of tar, and stirs the mixture.

This ointment is highly useful as a stimulant application in various scaly and scabby eruptions, particularly in psoriasis and lepra, and in that form of porrigo usually called tinea capitis, or scaldhead. In the last-mentioned affection, it should be applied night and morning; and in bad cases the patient should constantly wear a cap, thickly coated internally with the ointment. W.

UNGUENTUM PLUMBI ACETATIS. *Ed.*, *Dub.* CERATUM PLUMBI ACETATIS. *Lond.* *Ointment of Acetate of Lead.*

"Take of Simple Ointment *twenty ounces;* Acetate of Lead, in fine powder, *one ounce.* Mix them thoroughly." *Ed.*

The *London College* melts *five ounces* of white wax in *eighteen fluidounces* of olive oil; then adds gradually *five drachms* of powdered acetate of lead previously rubbed with *two fluidounces* of olive oil; and stirs with a spatula till they are incorporated. The *Dublin College* mixes *an ounce* of acetate of lead with *a pound* of ointment of white wax, previously melted with a gentle heat; using the avoirdupois weights in the process.

This is an excellent ointment in burns, and other excoriated or ulcerated surfaces, particularly blisters in an inflamed state. W.

UNGUENTUM PLUMBI CARBONATIS. *U. S.*, *Ed.*, *Dub.* *Ointment of Carbonate of Lead.*

"Take of Carbonate of Lead, in very fine powder, *two ounces;* Simple Ointment *a pound.* Add the Carbonate of Lead to the Ointment previously softened over a gentle fire, and mix them." *U. S.*

The *Edinburgh College* prepares this ointment by mixing thoroughly *one ounce* of carbonate of lead with *five ounces* of simple ointment. The *Dublin College* employs *three ounces* of the carbonate and *a pound* of the ointment, using the avoirdupois weights.

This ointment is used for the same purposes as the preceding. W.

UNGUENTUM PLUMBI COMPOSITUM. *Lond.* *Compound Ointment of Lead.*

"Take of Lead Plaster *three pounds;* Olive Oil *eighteen fluidounces;* Prepared Chalk *six ounces;* Diluted Acetic Acid *six fluidounces.* Dissolve the

Plaster in the Oil with a slow fire, then add first the Chalk and afterwards the Acid, constantly stirring until they become cold." *Lond.*

Employed as a dressing for flabby indolent ulcers. W.

UNGUENTUM PLUMBI IODIDI. *Lond., Dub. Ointment of Iodide of Lead.*

"Take of Iodide of Lead *an ounce;* Lard *eight ounces.* Rub them together." *Lond.*

The *Dublin College* rubs together *a drachm* of the iodide and *seven drachms* of simple ointment.

Employed as a discutient in chronic glandular swellings, and enlargements of the joints. W.

UNGUENTUM POTASSII IODIDI. *U. S., Lond., Dub. Ointment of Iodide of Potassium.*

"Take of Iodide of Potassium, in fine powder, *a drachm;* Boiling Water *a fluidrachm;* Lard *an ounce.* Dissolve the Iodide of Potassium in the Water, and mix the solution with the Lard." *U. S.*

The *London* process is the same as the above, using double the quantity of materials. The *Dublin College* uses *a drachm* of the iodide, *half a* [*fluid*] *drachm* of distilled water, and *seven drachms* of simple ointment, and proceeds in the same manner.

The preparation is apt to become discoloured by time in consequence of the liberation of iodine. It is said that this may be prevented by mixing two drops of the *Liquor Potassæ* with each ounce of the freshly prepared ointment. (*Am. Journ. of Pharm.*, xxiii. 123.)

This ointment is employed for the discussion of goitres, scrofulous tumours, and other indolent swellings; and is sometimes preferred to the ointment of iodine, as it does not, like that, discolour the skin. W.

UNGUENTUM SAMBUCI. *Lond. Elder Ointment.*

"Take of Elder [flowers], Lard, each, *two pounds.* Boil the Elder in the Lard till it becomes crisp; then express through linen." *Lond.*

Elder flowers impart odour to lard without adding to its virtues. An ointment, prepared in like manner from the leaves, has a green colour, and is popularly employed as a cooling application in England. W.

UNGUENTUM SIMPLEX. *U. S., Ed.* UNGUENTUM CERÆ ALBÆ. *Dub. Simple Ointment.*

"Take of White Wax *a pound;* Lard *four pounds.* Melt them together with a moderate heat, and stir them constantly till they are cold." *U. S.*

The *Dublin* process corresponds with the above. The *Edinburgh College* orders *five fluidounces and a half* of olive oil, and *two ounces* of white wax.

This is emollient, and is occasionally employed as a mild dressing to blistered or excoriated surfaces, but more frequently as a vehicle for more active substances. It is the basis of several officinal ointments. W.

UNGUENTUM STRAMONII. *U. S. Ointment of Stramonium.*

"Take of Extract of Stramonium Leaves *a drachm;* Lard *an ounce.* Rub the Extract with a little water until uniformly soft, and then with the Lard." *U. S.*

This is a more certain preparation than that of the former editions of the U. S. Pharmacopœia, which was made by boiling the fresh leaves in lard.

The ointment of stramonium is a useful anodyne application in irritable ulcers, painful hemorrhoids, and some cutaneous eruptions. W.

UNGUENTUM SULPHURIS. *U. S., Lond., Ed., Dub. Sulphur Ointment.*

"Take of Sulphur *a pound;* Lard *two pounds.* Mix them." *U. S.*

The *London College* employs the same proportions as the U.S. Pharmacopœia; the *Edinburgh*, *four ounces* of lard, and *one ounce* of sublimed sulphur; and the *Dublin*, *a pound* of sublimed sulphur and *four pounds* of prepared lard.

Sulphur ointment is a specific for the itch. It should be applied every night till the complaint is cured; and it is recommended that only one-fourth of the body should be covered at a time. We have usually directed it to be applied over the whole surface, and have found no inconvenience to result. Four applications are usually sufficient to effect a cure. It is thought by some that powdered roll sulphur is more efficacious than the sublimed. Sulphur ointment, applied freely over the variolous eruption, in its early stage, is said to prevent the maturation of the pustules and consequent pitting. (See *Am. Journ. of Med. Sci., N. S.*, ii. 196.) The disagreeable odour of the ointment may be in some measure concealed by a little oil of lemons, or oil of bergamot. W.

UNGUENTUM SULPHURIS COMPOSITUM. *U. S.*, *Lond.* *Compound Sulphur Ointment.*

"Take of Sulphur *an ounce;* Ammoniated Mercury, Benzoic Acid, each, *a drachm;* Oil of Bergamot, Sulphuric Acid, each, *a fluidrachm;* Nitrate of Potassa *two drachms;* Lard *half a pound.* To the Lard, previously melted with a moderate heat, add the other ingredients, and stir them constantly till they are cold." *U. S.*

This ointment is essentially different from that which is directed, under the same name, by the *London College.* Though, perhaps, not more efficient than the simple sulphur ointment in the cure of itch, it has a less unpleasant smell, and may be advantageously applied to the cure of other eruptive affections, such as tinea capitis and crusta lactea.

"Take of Sulphur *four ounces;* White Helleborc, in powder, *ten drachms;* Nitrate of Potassa, in powder, *two scruples;* Soft Soap *four ounces;* Lard *a pound.* Rub them together." *Lond.*

This is thought to be more efficacious than the simple sulphur ointment; but the white hellebore renders it also more irritating. W.

UNGUENTUM SULPHURIS IODIDI. *U.S.*, *Lond.* *Ointment of Iodide of Sulphur.*

"Take of Iodide of Sulphur *half a drachm;* Lard *an ounce.* Rub the Iodide with a little of the Lard, then add the remainder, and mix them." *U. S.*

The *London* process is identical with the above.

This is admirably adapted, as a local remedy, to the treatment of most chronic cutaneous eruptions, unattended with inflammation; but it is especially useful in psoriasis, lepra, porrigo, and the very advanced stages of eczema and impetigo, when they have become dry. W.

UNGUENTUM TABACI. *U. S.* *Tobacco Ointment.*

"Take of fresh Tobacco, cut in pieces, *an ounce;* Lard *a pound.* Boil the Tobacco in the Lard over a gentle fire till it becomes friable; then strain through linen." *U. S.*

In the first edition of the U.S. Pharmacopœia, this ointment, under the name of "Tobacco Liniment," was directed to be prepared with common dried tobacco; but in this condition the leaves do not yield their virtues to lard. The error was corrected in the second edition. Though the tobacco plant is not an object of general culture in the Northern States, it may readily be produced in gardens, in quantities sufficient to supply any demand for the fresh leaves which can possibly arise.

Fresh narcotic vegetables yield their active principles, and chlorophylle or green colouring matter to oleaginous substances, when heated with them; and ointments have long been prepared in this manner. In the pharmacy of the

continent of Europe, olive oil is frequently employed as the solvent, and the resulting preparations are called *olea infusa*. Several of these are ordered by the French Codex, as the oils of henbane, stramonium, tobacco, &c. Lard is preferred in British and American pharmacy, as affording preparations of a more convenient consistence. The boiling takes place at a lower temperature than that necessary for the evaporation of the lard or oil, and is owing to the escape of the watery parts of the plants. It should be continued till all the water is driven off; as this, if allowed to remain, would render the ointment more liable to spontaneous decomposition; and, besides, the colouring matter of the narcotic is not freely extracted till after the dissipation of the water.

Tobacco ointment is useful in irritable ulcers, and various cutaneous eruptions, particularly *tinea capitis;* but great care must be taken, especially in children, not to employ it in such quantities as to endanger the production of the constitutional effects of the narcotic. W.

UNGUENTUM VERATRI ALBI. *U.S. Ointment of White Hellebore.*

"Take of White Hellebore [root], in powder, *two ounces;* Oil of Lemons *twenty minims;* Lard *eight ounces.* Mix them." *U. S.*

This ointment is sometimes employed with advantage in the itch. It is less disagreeable, but also less certain than the sulphur ointment. It should be employed with caution in children. W.

UNGUENTUM ZINCI OXIDI. *U.S.* Unguentum Zinci. *Lond., Ed.* Unguentum Zinci Oxydi. *Dub. Ointment of Oxide of Zinc.*

"Take of Oxide of Zinc *an ounce;* Lard *six ounces.* Mix them." *U. S., Lond.*

The *Edinburgh College* employs *six ounces* of simple liniment, and *one ounce* of oxide of zinc; the *Dublin, two ounces* of the oxide, and *twelve ounces* of ointment of white wax (simple ointment). By the latter the ointment is melted before the addition of the oxide.

This is employed as a mild astringent application in chronic ophthalmia with a relaxed state of the vessels, in cutaneous eruptions, and in sore nipples and other instances of excoriation or ulceration. It has taken the place of the discarded *unguentum tutiæ*, or *tutty ointment*, prepared from tutty or the impure oxide of zinc, by mixing it with five parts of simple ointment. W.

VERATRIA.

Veratria.

VERATRIA. *U.S., Lond., Ed. Veratria.*

"Take of Cevadilla, bruised, *two pounds;* Alcohol *three gallons;* Sulphuric Acid, Solution of Ammonia, Purified Animal Charcoal, Magnesia, each, *a sufficient quantity.* Boil the Cevadilla in a gallon of the Alcohol, in a retort with a receiver attached, for an hour, and pour off the liquor. To the residue add another gallon of the Alcohol, together with the portion recently distilled, again boil for an hour, and pour off the liquor. Repeat the boiling a third time with the remaining Alcohol, and with that distilled in the previous operation. Press the Cevadilla, mix and strain the liquors, and by means of a water-bath distil off the Alcohol. Boil the residue three or four times in water acidulated with Sulphuric Acid, mix and strain the liquors, and evaporate to the consistence of syrup. Add Magnesia, in slight excess, shake the mixture frequently, then express, and wash what remains. Repeat the expression and washing two or three times, and, having dried the residue, digest it with a gentle heat several

times in alcohol, and strain after each digestion. Distil off the alcohol from the mixed liquors, boil the residue for fifteen minutes in water with a little Sulphuric Acid and Purified Animal Charcoal, and strain. Having thoroughly washed what remains, mix the washings with the strained liquor, evaporate with a moderate heat to the consistence of syrup, and then drop in as much Solution of Ammonia as may be necessary to precipitate the Veratria. Lastly, separate and dry the precipitate." *U. S.*

The *London College* has transferred veratria to its Materia Medica list.

"Take *any convenient quantity* of Cevadilla; pour boiling water over it in a covered vessel, and let it macerate for twenty-four hours; remove the Cevadilla, squeeze it, and dry it thoroughly with a gentle heat. Beat it now in a mortar, and separate the seeds from the capsules by a brisk agitation in a deep narrow vessel. Grind the seeds in a coffee-mill, and form them into a thick paste with Rectified Spirit. Pack this firmly in a percolator, and pass Rectified Spirit through it till the Spirit ceases to be coloured. Concentrate the spirituous solutions by distillation so long as no deposit forms; and pour the residuum while hot into twelve times its volume of cold water. Filter through calico, and wash the residuum on the filter so long as the washings precipitate with ammonia. Unite the filtered liquid with the washings, and add an excess of ammonia. Collect the precipitate on a filter, wash it slightly with cold water, and dry it first by imbibition with filtering paper, and then in the vapour-bath. A small additional quantity may be got by concentrating the filtered ammoniacal fluid and allowing it to cool." *Ed.*

In the U. S. process the first step is to obtain a tincture of cevadilla. In the Edinburgh process, the use of alcohol is preceded by measures calculated to bring the seeds into a proper state for its action. This is not satisfactorily effected by mere bruising. The seeds are not thus separated from the capsules; and, on account of their elasticity, they cannot be conveniently comminuted in a mortar. The mode of proceeding given in the Edinburgh Pharmacopœia was suggested by Christison, and is said by him to answer the purpose. In the U. S. process, the tincture, when made, is evaporated to the consistence of an extract. This contains the veratria combined with some vegetable acid, probably the gallic, as it exists in the seeds. From the extract the alkali is dissolved by the acidulated water, which at the same time converts it in great measure into a sulphate, a small portion possibly remaining in the solution combined with an excess of the native acid. The magnesia combines with the acids and throws down the veratria, which is then taken up by alcohol, and again yielded in a purer state by evaporation. To purify it still further, it is redissolved in water by the agency of sulphuric acid, is submitted to the action of animal charcoal, and is finally precipitated by ammonia. In the Edinburgh process, the tincture is concentrated until it begins to let fall a precipitate, and is then poured into water, which throws down the resin and oil with a portion of the colouring matter, and retains the salt of veratria. This is then decomposed by ammonia, and the precipitated veratria is slightly washed with cold water to free it from adhering impurities. If much water is employed in the washing, a considerable portion of the veratria is lost, in consequence of being in some degree soluble in that menstruum in its ordinary impure state.*

* Mr. James Beatson, Manufacturing Chemist of the U. S. Naval Laboratory at New York, recommends the following method of preparing veratria as less complicated and troublesome than the officinal, and quite satisfactory in its results. Take 73 pounds (avoirdupois) of cevadilla, rub it upon a coarse wire sieve so as to separate the seeds from the capsules, and reduce the former to a course powder by a Swift's drug mill. Pass the capsules also through the mill, separate the finer portion, and mix it with the ground seeds. Moisten the mixture with alcohol, and allow it to stand 12 hours; then introduce it

The U. S. process is essentially that recommended by M. Couerbe. The veratria obtained by it, though not pure, is sufficiently so for medical use. A drachm of it, in this state, may be procured from a pound of cevadilla. Besides veratria, M. Couerbe states that principles, which he calls respectively *sabadillia* and *veratrin*, are also contained in this product. These are separated in the following manner. Into the solution of impure sulphate of veratria obtained in the above process, nitric acid is to be introduced by drops. This occasions an abundant precipitate, from which the clear liquor is to be decanted. A weak solution of potassa is then to be added to the liquor, and the precipitate which it produces is to be washed with cold water, and treated with boiling alcohol. The substance obtained by evaporating the alcohol yields the *sabadillia* to boiling water, which deposits it upon cooling; a substance, called by M. Couerbe *resini-gum* of sabadillia, remaining in solution. If the residue of the substance, treated as just mentioned with boiling water, be submitted to the action of ether, it yields to this liquid the proper *veratria*, which may be obtained entirely pure by the spontaneous evaporation of the ether. The matter remaining undissolved is the resinous substance which M. Couerbe calls *veratrin*. *Sabadillia* is white, crystallizable, insupportably acrid, fusible by heat, readily soluble in hot water, which deposits it upon cooling, very soluble in alcohol, and wholly insoluble in ether. It is capable of saturating the acids. (*Journ. de Pharm.*, xix. 527.) According to Simon, sabadillia is a compound of resinate of soda and resinate of veratria. Fr. Hübschmann confirms the views of Couerbe as to the separate existence of sabadillia. He obtained it by treating the matter considered as veratria with ether, which removed the pure veratria, and left the sabadillia. The latter does not irritate the nostrils like veratria. (*Am. Journ. of Pharm.*, xxv. 133.)

Veratria, when pure, is white, pulverulent, uncrystallizable, inodorous, extremely acrid, fusible by heat, scarcely soluble in cold water, soluble in a thousand parts of boiling water which it renders sensibly acrid, dissolved freely by alcohol, less so by ether, and capable of neutralizing the acids, with several of which, particularly the sulphuric and muriatic, it forms crystallizable salts.

In the impure state in which it is obtained by either of the above officinal processes, it is a grayish or brownish-white powder, without odour, and of a bitter, acrid taste, producing a sense of tingling or numbness in the tongue, and exciting violent sneezing and coryza when admitted into the nostrils. The composition of veratria is expressed, according to Couerbe, by the formula $NC_{34}H_{22}O_6$. It may be recognised by its sensible properties, incapability of being crystallized, combustibility, fusibility, peculiar solubilities, alkaline reaction, the intense red colour it assumes upon contact with concentrated sulphuric acid, the yellow solution it forms with nitric acid, and the white precipitates which its solution in dilute acetic acid yields with ammonia and the infusion of galls. It is entirely dissipated by a red heat. It is said sometimes to be sophisticated with lime, which is easily detected by incineration, and may be separated by dissolving the powder in diluted alcohol, precipitating by sulphuric acid, filtering, evaporating the alcohol, and precipitating the veratria by ammonia. (*Chem.*

into a displacement apparatus, and pour upon it 30 gallons of alcohol. When a convenient quantity of the liquid has passed, submit it to distillation, and return the distilled alcohol to the displacement apparatus; and proceed in the same way until the cevadilla is thoroughly exhausted. Collect all the alcoholic liquor from the exhausted seeds, and continue the distillation until the tincture has a syrupy consistence. Pour this while hot into eight times its volume of cold water, throw the whole on a calico filter, and wash until the washings cease to indicate the presence of veratria. Mix the washings with what first passed through the filter, and add liquor ammoniæ in excess (about 4 pounds). Wash the precipitated veratria with cold water, and dry it with a very gentle heat. Mr. Beatson obtained by this process eleven and a quarter ounces of pure veratria, but faintly tinged with colouring matter. (*Am. Journ. of Pharm.*, xxvi. 5.)—*Note to the tenth edition.*

Gaz., Feb. 1845, p. 73.) It may be used either in the uncombined state, or united with acids; as in both forms it produces essentially the same effects.

Medical Properties and Uses.—Veratria is locally irritant, and exerts a peculiar influence on the nervous system. Rubbed upon the skin it excites a sensation of warmth and a peculiar tingling, which, when the application is continued for a considerable length of time, extends, according to Turnbull, over the whole surface of the body. Sometimes an evanescent blush is produced, and still more rarely an eruption upon the skin; but, according to the same author, no marks of inflammation are in general evinced. Upon the denuded cutis, however, veratria and its salts are powerfully irritating; in the mouth and fauces produce an almost insupportable sense of acrimony; and snuffed up the nostrils excite violent sneezing. Magendie states that, when taken internally in the dose of a quarter of a grain, they promptly produce abundant alvine evacuations, and in larger doses provoke more or less violent vomiting. Other experimenters have observed similar effects. Dr. Turnbull, on the contrary, says that he has very seldom found them to purge, even when largely administered, and that not unfrequently constipation comes on during their employment. According to this author, their first effect, when given in moderate doses, is a feeling of warmth in the stomach, gradually extending itself over the abdomen and lower part of the chest, and ultimately to the head and extremities. If the medicine is continued, this feeling of warmth is followed by a sense of tingling, similar to that produced by the external use of the medicine, which manifests itself in different parts of the body, and sometimes over the whole surface, and is frequently accompanied by perspiration and some feeling of oppression. Occasionally also diuresis is produced. A still further continuance of the medicine, or the use of large doses, excites nausea and vomiting. It occasions no narcotic effects. In over-doses it is a violent poison.

The diseases in which veratria has been employed are chiefly gout, rheumatism, and neuralgia. M. Piedagnel has used it with great supposed advantage in acute articular rheumatism, which he has found generally to get well under its use in seven or eight days. (See *Am. Journ. of Med. Sci.*, N. S., xxvi. 496.) Dr. Turnbull has found it useful also in dropsy, and in diseases of the heart, particularly those of a functional character. He thinks he has also seen it do good in structural diseases of that organ, but chiefly by acting as a diuretic, and thereby removing effusion in the pericardium. Veratria has also been employed in various nervous affections, as paralysis, hooping-cough, epilepsy, hysteria, and disorders dependent upon spinal irritation. For internal use the salts of veratria are preferred. From one-twelfth to one-sixth of a grain may be given in the form of pill, and repeated every three hours till the effects of the medicine are experienced. Dr. Turnbull prefers the tartrate, as less disposed to irritate the stomach. The sulphate or acetate, however, may be used. Any one of these salts may be readily prepared by treating veratria with water acidulated with the acid to perfect neutralization, and then evaporating to dryness.

But veratria is much more employed externally than by the stomach, and is applicable in this way to all the complaints already mentioned. It may be used either dissolved in alcohol, or rubbed up with lard or other unctuous substance in the proportion of from ten to twenty grains or more to the ounce. Of the ointment thus prepared, Dr. Turnbull directs a portion of the size of a large nut to be rubbed upon the skin over the part affected, night and morning, from five to fifteen minutes, or until the more urgent symptoms are relieved. Veratria may be used in this way to the amount of from four to eight grains in the day. Care must be taken that the cuticle is sound over the parts to which it is applied. When the skin is irritable, smaller quantities than those above mentioned must be used. W.

VINA MEDICATA.

Medicated Wines.

The advantages of wine as a pharmaceutic menstruum are that, in consequence of the alcohol it contains, it dissolves substances insoluble in water, and, to a certain extent, resists their tendency to spontaneous change; while, at the same time, it is less stimulant than rectified or proof spirit, both from its smaller proportion of alcohol, and from the modified state in which this fluid exists in its composition. The acid which it usually contains, serves in some instances to increase its solvent power. But most wines, particularly the light varieties, are liable to undergo decomposition; and even the strongest acquire such a liability from the principles which they extract from vegetable substances; so that medicated wines, though they keep much better than infusions or decoctions, are inferior in this respect to the tinctures. The proportion of alcohol, moreover, is not constant; and the preparations, therefore, made with them, are of unequal strength. From these causes, few medicated wines are at present retained. In the choice of wine, the purest and most generous should be selected. Sherry, as directed by the U. S. and British Pharmacopœias, Teneriffe, or Madeira should be preferred. The medicated wines, in consequence of their liability to change, should be prepared in small quantities, without heat, and should be kept in well stopped bottles in a cool place.

The *London College* directs that "medicated wines should be prepared in covered glass vessels, and frequently agitated during the maceration." W.

VINUM ALOËS. *U. S.*, *Lond.*, *Ed.* *Wine of Aloes.*

"Take of Aloes, in powder, *an ounce;* Cardamom [seeds], bruised, Ginger, bruised, each, *a drachm;* White Wine [sherry] *a pint.* Macerate for fourteen days, with occasional agitation, and filter through paper." *U. S.*

"Take of Socotrine or Hepatic Aloes, in powder, *two ounces;* Canella, in powder, *four drachms;* Sherry Wine *two pints* [Imperial measure]. Macerate for seven days, and filter." *Lond.*

"Take of Socotrine or East India Aloes *an ounce and a half;* Cardamom Seeds, ground, Ginger, in coarse powder, of each, *a drachm and a half;* Sherry *two pints* [Imperial measure]. Digest for seven days, and strain through linen or calico." *Ed.*

The wine of aloes is a warm stomachic purgative, useful in constipation dependent on a want of due irritability of the alimentary canal, and in complaints connected with this state of the bowels. It has long been used in chlorosis, amenorrhœa, dyspepsia, gout, paralysis, &c. It is said to leave behind it a more lax condition of the bowels than most other cathartics. The dose as a stomachic is one or two fluidrachms, as a purgative from half a fluidounce to two fluidounces. W.

VINUM COLCHICI RADICIS. *U. S.* VINUM COLCHICI. *Lond.*, *Ed.* *Wine of Colchicum Root.*

"Take of Colchicum Root, well bruised, *a pound;* White Wine [sherry] *two pints.* Macerate for fourteen days, with occasional agitation; then express strongly, and filter through paper.

"Wine of Colchicum Root may also be prepared by macerating as above, then transferring to a percolator, and, after the liquor has ceased to pass, pouring so much wine upon the residue that the filtered liquor obtained may measure *two pints.*" *U. S.*

"Take of dried Meadow-saffron Cormus, sliced, *eight ounces;* Sherry Wine *two pints* [Imperial measure]. Macerate for seven days, and filter." *Lond.*

The *Edinburgh College* directs the same quantities of materials as the London, and orders digestion for seven days, straining, strong expression, and filtering.

This is intended to be a saturated vinous tincture of colchicum. As the colchicum root imported into the United States is of variable strength, the only method by which an active preparation can be ensured, is to employ a large quantity of the bulb in proportion to that of the menstruum. If the former should happen to be in excess, no other injury could result than a slight pecuniary loss; while a deficiency in the strength of the preparation would frequently be of serious detriment in urgent cases of disease. We have never been disappointed in obtaining the effects of colchicum from the wine which we knew to have been prepared according to the directions of the U. S. Pharmacopœia; while that which has been made with a smaller quantity of the bulb has often failed in our hands. A wine prepared from the fresh bulb is occasionally imported from England, and is thought by some to be more efficacious than our officinal preparation. The dose of the officinal wine is from ten minims to a fluidrachm, to be repeated three or four times a day, or more frequently in severe cases, till its effects are experienced. In gout it is frequently given in connexion with magnesia and its sulphate; and in neuralgic cases we have found much advantage from combining it with the solution of sulphate of morphia, especially when we have desired to give it a direction rather to the skin than the bowels. It has been employed externally with asserted advantage in rheumatism. In overdoses it may produce fatal effects. Death is said to have occurred in one instance from two drachms of the wine; but much more would probably in general be requisite to produce this result. W.

VINUM COLCHICI SEMINIS. *U.S.* *Wine of Colchicum Seed.*

"Take of Colchicum Seed, bruised, *four ounces;* White Wine [sherry] *two pints.* Macerate for fourteen days, with occasional agitation; then express, and filter through paper." *U. S.*

As the seeds of colchicum are less liable to injury than the bulb, and are, therefore, of more uniform strength, there is not the same necessity for preparing a saturated tincture. This wine corresponds in strength with the tincture of colchicum seed. (See *Tinctura Colchici Seminis.*) In the account of the seeds given in the first part of this work (*page* 275), it is stated, on the authority of Dr. Williams, who introduced the seeds into use, that their active properties reside in their coating, and that it is, therefore, not advisable to bruise them in preparing the wine or tincture. But this has been shown to be an error by the experiments of Mr. Bonnewyn, who found a larger proportion of colchicia in a tincture of the bruised than in one of the unbruised seeds. (See *Am. Journ. of Pharm.*, xxvi. 120.) The dose is one or two fluidrachms. Two fluidounces have proved fatal. W.

VINUM ERGOTÆ. *U.S.* *Wine of Ergot.*

"Take of Ergot, bruised, *two ounces;* White Wine [sherry] *a pint.* Macerate for fourteen days, with occasional agitation; then express, and filter through paper." *U. S.*

The large proportion of fixed oil in ergot interferes with the solvent action of the menstruum, unless the grains are finely powdered. It is, therefore, best to employ the ergot in this process well powdered, instead of merely bruised, as officinally directed.

The dose of this wine is for a woman in labour two or three fluidrachms; for other purposes, one or two fluidrachms, to be repeated several times a day, and gradually increased if necessary. W.

VINUM GENTIANÆ. *Ed. Wine of Gentian.*

"Take of Gentian, in coarse powder, *half an ounce;* Yellow Bark, in coarse powder, *one ounce;* Bitter-orange Peel, dried and sliced, *two drachms;* Canella, in coarse powder, *one drachm;* Proof Spirit *four fluidounces and a half;* Sherry *one pint and sixteen fluidounces* [Imperial measure]. Digest the root and barks for twenty-four hours in the Spirit; add the Wine, and digest for seven days more; strain and express the residuum strongly, and filter the liquors." *Ed.*

This is a stomachic bitter, sometimes employed to promote appetite and invigorate digestion. The dose is from four to eight fluidrachms. W.

VINUM IPECACUANHÆ. *U.S., Lond., Ed., Dub. Wine of Ipecacuanha.*

"Take of Ipecacuanha, bruised, *two ounces;* White Wine [sherry] *two pints.* Macerate for fourteen days, with occasional agitation; then express, and filter through paper.

"Wine of Ipecacuanha may also be prepared by moistening the Ipecacuanha, in coarse powder, thoroughly with Wine, allowing it to stand for twenty-four hours, then transferring it to a percolator, and pouring Wine gradually upon it until two pints of filtered liquor are obtained." *U. S.*

The *London College* takes *two ounces and a half* of the bruised root, and *two Imperial pints* of sherry wine, and macerates for seven days; the *Edinburgh*, the same ingredients, in the same proportions, and digests for a week; the *Dublin*, *two ounces and a half* [avoirdupois] of aloes, and *two Imperial pints* of sherry wine, and macerates for two weeks.

The preparations of the different Pharmacopœias are virtually of the same strength. Wine of ipecacuanha possesses all the medical properties of the root, and may be used as a substitute when it is desirable to administer the medicine in the liquid form. As it is milder, without being less efficacious than antimonial wine, it is in some instances preferable as an emetic in infantile cases, especially when the antimonial, as not unfrequently happens, is disposed to irritate the bowels. Under the same circumstances, it may be used as an expectorant and diaphoretic; and the effects of the Dover's powder may be obtained by combining it with laudanum or other liquid preparation of opium. The dose as an emetic for an adult is a fluidounce; as an expectorant and diaphoretic, from ten to thirty minims. A fluidrachm may be given as an emetic to a child one or two years old, and repeated every fifteen minutes till it operates. W.

VINUM OPII. *U.S., Lond., Ed., Dub. Wine of Opium. Sydenham's Laudanum.*

"Take of Opium, in powder, *two ounces;* Cinnamon, bruised, Cloves, bruised, each, *a drachm;* White Wine [sherry] *a pint.* Macerate for fourteen days, with occasional agitation; then express, and filter through paper." *U. S.*

The *London College* takes *two ounces and a half* of extract of opium, *two drachms and a half* of bruised cinnamon, *the same quantity* of bruised cloves, and *two Imperial pints* of sherry wine; and macerates for seven days. The *Edinburgh College*, to the same quantity of cinnamon and cloves, adds *three ounces* of opium, and *two Imperial pints* of sherry wine, and digests for a week. The *Dublin College* takes *three avoirdupois ounces* of opium, and *two Imperial pints* of sherry wine, and macerates for fourteen days.

The wine made according to the directions of the U. S. Pharmacopœia is a saturated vinous tincture of opium. It contains about the same proportions of the ingredients as the *laudanum of Sydenham*, from which it differs only in wanting a drachm of saffron. The spices which it contains are thought to adapt it to certain states of the stomach or system, in which the simple tincture of opium is found to produce unpleasant effects; but the same end may be obtained

by an extemporaneous addition of some aromatic oil to the latter. Mr. Ware recommends it as a local application to the eye, in the latter stages of ophthalmia, when the vessels of the conjunctiva still remain turgid with blood. Two or three drops are introduced into the eye every morning till the redness disappears. The dose of the wine of opium is the same with that of the tincture.* W.

VINUM RHEI. *U.S., Ed., Dub. Wine of Rhubarb.*

"Take of Rhubarb, bruised, *two ounces;* Canella, bruised, *a drachm;* Diluted Alcohol *two fluidounces;* White Wine [sherry] *a pint.* Macerate for fourteen days, with occasional agitation; then express, and filter through paper.

"Wine of Rhubarb may also be prepared by mixing the Rhubarb and Canella, in coarse powder, with the Diluted Alcohol, allowing the mixture to stand for twenty-four hours, then transferring it to a percolator, and pouring Wine gradually upon it until eighteen fluidounces of filtered liquor are obtained." *U. S.*

The *Edinburgh College* takes *five ounces* of rhubarb, in coarse powder, *two drachms* of canella, in coarse powder, *five fluidounces* of proof spirit, and *one pint and fifteen fluidounces* [Imperial measure] of sherry wine, and digests for seven days. The *Dublin College* takes *three avoirdupois ounces* of the rhubarb, *two drachms* [Dub. weight] of the canella, and *two Imperial pints* of sherry wine, and macerates for two weeks.

This is a warm cordial laxative, applicable to debilitated conditions of the system or alimentary canal requiring evacuation of the bowels. The dose is from one to four fluidrachms or more, according to the amount of effect required, and the condition of the patient. W.

VINUM TABACI. *U. S., Ed. Wine of Tobacco.*

"Take of Tobacco, cut in pieces, *an ounce;* White Wine [sherry] *a pint.* Macerate for fourteen days, with occasional agitation; then express, and filter through paper." *U. S.*

The *Edinburgh College* takes *three ounces and a half* of tobacco and *two Imperial pints* of sherry wine, and digests for seven days.

The dose of the wine of tobacco, as a diuretic, is from ten to thirty minims. It is very seldom used. W.

VINUM VERATRI ALBI. *U.S.* VINUM VERATRI. *Lond. Wine of White Hellebore.*

"Take of White Hellebore [root], bruised, *four ounces;* White Wine [sherry] *a pint.* Macerate for fourteen days with occasional agitation; then express, and filter through paper." *U. S.*

The *London College* takes *eight ounces* of the sliced root, and *two Imperial pints* of sherry wine, and macerates for seven days.

It has been supposed that the wine of white hellebore, in consequence of the veratria which it contains, would act in the same manner with colchicum in the cure of gout and rheumatism; but it is uncertain and occasionally violent in its operation, and is very little used. The dose is ten minims two or three times a day, to be gradually increased till the peculiar effects of the medicine are experienced. W.

* *Rousseau's laudanum* is a tincture of opium made with very weak alcohol, which may be classed with propriety along with the above preparation. It is made according to the following formula. "Take of white honey *twelve ounces;* warm water *three pounds.* Having dissolved the honey, set the solution aside in a warm place; and, as soon as fermentation begins, add of selected opium *four ounces,* previously dissolved in *twelve ounces* of water. Allow the mixture to stand for a month at the temperature of 24° Reaumur (86° F.); then strain, filter, and evaporate to *ten ounces;* finally strain, and add *four ounces and a half* of alcohol of 20° B. Seven drops contain about a grain of opium." (*Pharmacop. Univers.*, ii. 265.)

ZINCUM.

Preparations of Zinc.

ZINCI ACETAS. *U. S., Dub. Acetate of Zinc.*

"Take of Acetate of Lead *a pound;* Zinc, granulated, *nine ounces;* Distilled Water *three pints.* Dissolve the Acetate of Lead in the Water and filter. Then add the Zinc to the solution, and agitate the mixture occasionally in a stopped bottle, for five or six hours, or until the liquid yields no precipitate with a solution of iodide of potassium. Filter the liquor, evaporate it with a moderate heat to one-fifth, acidulate it slightly with acetic acid, and set it aside to crystallize. Pour off the liquid, and dry the crystals on bibulous paper. Should the crystals be coloured, dissolve them in a pint and a half of distilled water, and, having heated the solution to ebullition, drop into it, while boiling, Precipitated Carbonate of Zinc, in successive portions, until a small quantity of the liquid, being filtered, passes colourless. Then filter the liquid, acidulate it slightly with acetic acid, and evaporate that crystals may form." *U. S.*

"Take of Acetate of Lead *one pound* [avoirdupois]; Sheet Zinc *four ounces* [avoird.]; Distilled Water *two pints and a half* [Imp. meas.]; Solution of Chlorinated Lime *a sufficient quantity.* Dissolve the Acetate of Lead in the Water, and, having placed the solution in a cylindric jar, immerse in it the Zinc rolled into a coil. After the lapse of twenty-four hours decant the liquid, and having reduced it by evaporation to fifteen ounces, drop into it, while boiling hot, the Solution of Chlorinated Lime, until a reddish precipitate ceases to form. It is now to be cleared by passing it through a filter, then acidulated by the addition of a few drops of acetic acid, and evaporated down to ten fluidounces, when, upon cooling, crystals will form. These, and any additional crystals obtained by the concentration of the mother liquor, should be dried on blotting-paper placed on a porous brick, and then preserved in a well stopped bottle." *Dub.*

In the *U. S.* process the lead is wholly precipitated by the zinc, which forms with the acetic acid the acetate of zinc in solution. In order to be sure that the solution is entirely free from lead, it is tested with iodide of potassium, which will produce a yellow precipitate in case any of the lead remains unprecipitated. The crystals of acetate of zinc, as first obtained, are apt to be coloured with iron. Should this be the case, a boiling solution of them in distilled water is treated by the addition of successive portions of precipitated carbonate of zinc, until a small quantity of the liquid, being filtered, passes colourless. The zinc of the carbonate of zinc precipitates the iron, and takes its place in the solution; and the iron is known to be all removed, when a portion of the solution is found, upon trial, to filter clear. This mode of purifying the acetate of zinc from iron was suggested by Professor Procter, and was adopted in the U. S. Pharmacopœia of 1850, in place of the mode by means of a solution of chlorinated lime, which he found to separate the iron imperfectly. The necessary carbonate of zinc may be obtained extemporaneously, by converting one-thirtieth of the coloured solution of the acetate into carbonate by precipitating it with carbonate of potassa in slight excess, as originally proposed by Prof. Procter. The precipitated carbonate, first washed from acetate of potassa, is added in the state of magma to the coloured solution boiling hot. During the evaporation of the solution of the acetate of zinc, a small portion of the acetic acid is lost; and hence the necessity of acidulating with a few drops of acetic acid before crystallizing. In the *Dublin* process the acetate of lead is decomposed in the same way precisely as in the U. S. formula; but the solution of acetate of zinc is not tested for lead, and the imperfect method of the former U. S.

Pharmacopœia for separating the iron by a solution of chlorinated lime is adopted. This precipitant, so far as it acts, sesquioxidizes the iron, and renders it insoluble, by its chlorine uniting with the hydrogen of water, and liberating oxygen. In relation to the acetate of zinc, see a paper by Mr. Ambrose Smith, contained in the *Amer. Journ. of Pharm.*, vol. vii. p. 14.

Properties, &c. Acetate of zinc, when carefully crystallized, is in colourless hexagonal plates, which effloresce in a dry air. As found in the shops it is in white micaceous crystals. It is very soluble in water, moderately soluble in rectified spirit, and has an astringent, metallic taste. The solution yields white precipitates with ferrocyanuret of potassium and hydrosulphate of ammonia. The precipitate, thrown down by ammonia from the pure salt, is entirely redissolved by an excess of the precipitant; but if sesquioxide of iron be present, it will be left undissolved. Acetate of zinc is decomposed by the mineral acids, with the escape of acetous vapours. It consists of one eq. of acetic acid 51, one of protoxide of zinc 40·3, and seven of water 63=154·3.

Medical Properties. Acetate of zinc is used as an external remedy only, for the most part as an astringent collyrium in ophthalmia, and as an injection in gonorrhœa, after the acute stage in these affections has passed. The strength of the solution, usually employed, is one or two grains to a fluidounce of distilled water. B.

CALAMINA PRÆPARATA. *U. S.*, *Lond.*, *Ed.* *Prepared Calamine.*

"Take of Calamine *a convenient quantity.* Heat it to redness, and afterwards pulverize it; then reduce it to a very fine powder in the manner directed for Prepared Chalk." *U. S.*

The *London* and *Edinburgh* Colleges place prepared calamine in the list of Materia Medica, with these definitions: "Native carbonate of zinc, calcined, reduced to a very fine powder, and elutriated." *Lond.* "Levigated impure carbonate of zinc." *Ed.* The Dublin College has dismissed it.

The object of this process is to bring the native carbonate of zinc, or calamine, to the state of an impalpable powder. It is first calcined, to render it more readily pulverizable, and then levigated and elutriated. During the calcination, water and more or less carbonic acid are driven off; so that little else remains than the oxide of zinc, and the earthy impurities originally existing in the mineral. Calamine, as sold in the English shops, is often a spurious article, composed principally of sulphate of baryta, as ascertained by Mr. R. Brett. (See *Calamina*, p. 150.)

Properties, &c. Prepared calamine is in the form of a pinkish or flesh-coloured powder, of an earthy appearance. Sometimes it is made up into small masses. It is almost wholly soluble in dilute sulphuric acid; emitting very few or no bubbles of carbonic acid. Potassa or ammonia, added to this solution, throws down a precipitate (mixed oxide and subsulphate), which is redissolved when either precipitant is added in excess. It is used only as an external application, being employed as a mild astringent and exsiccant in excoriations and superficial ulcerations. For this purpose it is usually dusted on the part, and hence the necessity for its being in very fine powder. It is often employed in the form of cerate. (See *Ceratum Calaminæ.*)

Off. Prep. Ceratum Calaminæ. B.

ZINCI CARBONAS PRÆCIPITATUS. *U. S.* Zinci Carbonas. *Dub.* *Precipitated Carbonate of Zinc.* *Carbonate of Zinc.*

"Take of Sulphate of Zinc, Carbonate of Soda, each, *a pound;* Boiling Water *a gallon.* Dissolve the Sulphate of Zinc and Carbonate of Soda, severally, in four pints of the Water. Then mix the solutions, and, having stirred the mixture, set it by that the powder may subside. Lastly, having poured off the

supernatant liquid, wash the Precipitated Carbonate of Zinc with hot water until the washings are nearly tasteless, and dry it with a gentle heat." *U. S.*

"Take of Solution of Chloride of Zinc *one pint* [Imp. meas.]; Crystallized Carbonate of Soda of Commerce *two pounds* [avoirdupois]; boiling Distilled Water *six pints* [Imp. meas.]. To the Carbonate of Soda, dissolved in the Water, add the Solution of Chloride of Zinc, in successive portions, and boil until gas ceases to be evolved. Collect the precipitate on a calico filter, and, having poured on distilled water until the washings cease to cause turbidity, when dropped into a solution of nitrate of silver containing free nitric acid, dry the product, first on blotting-paper placed on a porous brick, and finally by a steam or water heat." *Dub.*

This is a new officinal of the U. S. and Dublin Pharmacopœias. In view of the impurities and frequent falsification of the native carbonate of zinc, the revisers of the former work conceived that it would be advantageous to adopt as officinal the pure artificial carbonate, but without discarding the old preparation. This is retained under the changed name of *Calamina;* while its former officinal name of *Zinci Carbonas* is applied to the present preparation. In the *U. S.* formula a double decomposition takes place between the salts employed, resulting in the formation of sulphate of soda in solution, and carbonate of zinc which precipitates. Carbonate of soda is preferable to carbonate of potassa for decomposing the sulphate; since the former gives rise to sulphate of soda, which is more easily washed away than sulphate of potassa, derived from the latter. In the *Dublin* process the reacting salts are chloride of zinc and carbonate of soda, with the result of forming chloride of sodium in solution, and carbonate of zinc. Here the salt to be washed away is chloride of sodium, which, on account of its being less soluble, is not so easily removed as sulphate of soda. The washings are tested with nitrate of silver, until they no longer indicate the presence of a chloride. Boiling water is properly used in both processes, in order to obtain a pulverulent precipitate, which is readily washed. If cold solutions are used, a gelatinous precipitate is formed, which is washed with difficulty.

Properties, &c. Precipitated carbonate of zinc is in the form of a very soft, loose, white powder, resembling magnesia alba. It dissolves in dilute sulphuric acid with effervescence, forming a solution having the characters of a solution of sulphate of zinc. If adulterated with chalk, it will be only partly soluble in this acid. Precipitated carbonate of zinc is often sold under the incorrect name of flowers of zinc, a name which properly belongs only to the oxide, as obtained by combustion. When obtained from boiling solutions of sulphate of zinc and carbonate of soda, it has the composition $8ZnO,3CO_2+6HO$. (*Schindler.*) Lefort makes its composition the same. (*Journ. de Pharm.*, 3*e sér.*, xi. 329.) The basic character of the salt is explained by the fact that effervescence of carbonic acid always takes place on mixing the solutions. It is employed medicinally for the same purposes as prepared calamine, and is coming gradually into use. The U. S. Pharmacopœia orders a cerate made from it, as a substitute for calamine cerate. (See *Ceratum Zinci Carbonatis.*)

ZINCI CHLORIDUM. *U. S., Lond., Dub. Chloride of Zinc. Butter of Zinc.*

"Take of Zinc, in small pieces, *two ounces and a half;* Nitric Acid [sp. gr. 1·42], Prepared Chalk, each, *a drachm;* Muriatic Acid *a sufficient quantity.* To the Zinc, in a glass or porcelain vessel, add gradually sufficient Muriatic Acid to dissolve it; then strain, add the Nitric Acid, and evaporate to dryness. Dissolve the dry mass in water, add the Chalk, and, having allowed the mixture to stand for twenty-four hours, filter, and again evaporate to dryness." *U. S.*

"Take of Hydrochloric Acid *a pint* [Imp. meas.]; Distilled Water *two pints* [Imp. meas.]; Zinc, broken into pieces, *seven ounces;* Mix the Acid with the Water, and add to them the Zinc; and, when the effervescence is nearly finished, apply heat until bubbles are no longer given out. Pour off the solution, filter, and evaporate until a dry salt remains. Having fused this in a lightly covered crucible by a nearly red heat, pour it out on a flat and clean stone. Lastly, when it has become cold, break it into pieces, and keep it in a well-stopped vessel." *Lond.*

"Take of Solution of Chloride of Zinc *any convenient quantity*. Evaporate it down in a porcelain capsule so far, that, upon suffering the residual liquor to cool, it solidifies. Subdivide the product rapidly into fragments, and enclose them in a well-stopped bottle." *Dub.*

In the U. S. process the chloride of zinc is first formed in solution by dissolving zinc in muriatic acid. The nitric acid added has the effect to sesquioxidize any iron which may have existed as an impurity in the zinc employed. By evaporating to dryness and redissolving in water, most of the sesquioxide of iron is left behind. Lastly, in order to remove any remains of iron, a small portion of chalk is added, which precipitates it as a sesquioxide; and the mixture, after standing, is filtered and evaporated to dryness. This process is the same as that of the French Codex. The *London* differs from the U. S. process in dispensing with the use of nitric acid and chalk, and in fusing the dry salt formed. The *Dublin* College uses the solution of chloride of zinc, prepared by a distinct formula, and evaporates it to such an extent that the salt solidifies on cooling. As this preparation is used chiefly as a caustic, we should prefer the London process, in which the salt is fused. In relation to this chloride, the reader is referred to a paper by Mr. B. J. Crew in the *Am. Journ. of Pharm.*, May, 1853, p. 203.

M. Rhighini prepares this chloride by double decomposition between solutions of chloride of barium and sulphate of zinc. Sulphate of baryta is precipitated, and chloride of zinc remains in solution, from which it is obtained in white flaky crystals by due evaporation.

Properties, &c. Chloride of zinc is a grayish-white, translucent, deliquescent substance, having the softness of wax. When pure it is wholly soluble in water, alcohol, and ether; but, as prepared by the U. S. formula, it contains some oxychloride, which is left undissolved by water. According to M. Lassaigne, the commercial chloride of zinc sometimes contains as much as twelve per cent. of arseniate of zinc, which, being insoluble in an aqueous solution of chloride of zinc, will be left undissolved, when the chloride is treated with water. (*Phillips's Trans. of the Lond. Pharm.*, 1851, p. 375.) Its solution yields with nitrate of silver a white precipitate (chloride of silver) insoluble in nitric acid; and with ammonia and potassa a white precipitate, which is dissolved by those reagents when added in excess. The carbonates of potassa and soda also throw down a white precipitate, which is not dissolved by an excess of the precipitants. When exposed to heat chloride of zinc first melts and then sublimes. When pure it gives white precipitates with ferrocyanuret of potassium and hydrosulphate of ammonia. A blue precipitate with the former test would indicate iron, a black one with the latter, lead. It consists of one eq. of zinc 32·3, and one of chlorine 35·42=67·72.

Medical Properties and Uses. This chloride was introduced into medicine by Papenguth, and subsequently recommended by Prof. Hancke, of Breslau, and Dr. Canquoin, of Paris. Internally it has been given as an alterative and antispasmodic in scrofula, epilepsy, chorea, and, combined with hydrocyanic acid, in facial neuralgia. Its chief employment, however, has been as an escharotic, applied to cancerous affections, and to ulcers of an anomalous and intractable character. When thus used, it acts not merely by destroying the diseased struc-

ture, but by exciting a new and healthier action in the surrounding parts. As a caustic it has the advantage of not giving rise to constitutional disorder from absorption, an effect which is sometimes produced by the arsenical preparations.

Dr. Canquoin prepares the chloride of zinc as an escharotic, by thoroughly and quickly mixing it with wheat flour and water into a paste of four different strengths, containing severally an ounce of the chloride incorporated with two, three, four, and five ounces of flour; fifteen drops of water being added for every ounce of flour, or sufficient to form the paste. It is applied in cakes from a twelfth to a third of an inch in thickness, and produces an eschar more or less deep (from a line to an inch and a half), according to the thickness of the paste, the length of the application, and the nature of the part acted on. The strongest paste is applied to lardaceous and fibro-cartilaginous structures; the second to carcinomatous tumours, and very painful cancers which have not much thickness, and the third to cancerous affections in persons who have a dread of violent pain. These preparations, applied to the skin denuded of its cuticle by means of a blister, excite in a few minutes a sensation of heat, and afterwards violent burning pain. The eschar, which is white, thick, and very hard, falls off, by the aid of an emollient poultice, between the eighth and twelfth days. To destroy thick cancerous tumours, having an uneven surface, and situated in fleshy parts, Dr. Canquoin uses a caustic formed of one part of chloride of zinc, half a part of chloride of antimony, and two and a half parts of flour, made into a paste with water. In all cases, the caustic is to be reapplied, after the falling off of the eschar, until the whole morbid structure is destroyed. M. Bonnet has applied the paste of chloride of zinc to the treatment of aneurism. He announces the complete cure of one case of subclavian aneurism from a penetrating wound, by a continued series of applications of the paste. Every two or three days, the superficial layers of the slough were removed by a bistoury. At the end of the second month, the eschar began to detach itself without any hemorrhage, and the clot came away with the eschar. Chloride of zinc has also been used successfully by M. Bonnet, in conjunction with M. Gensoul, in the treatment of aneurism by anastomosis. (*Med. Times and Gaz.*, July 23, 1853.) Instead of flour, Dr. Alex. Ure, of Glasgow, mixes the chloride with pure anhydrous sulphate of lime in impalpable powder. He states that this has the advantages of furnishing a porous medium from which the escharotic gradually exudes into the morbid structure, and of forming afterwards, by acquiring a firmer consistence, an impervious case for the eschar. Mr. Calloway, of Guy's Hospital, has employed the chloride of zinc with considerable success in the treatment of nævi materni. He rubs it at intervals on the part, until the skin becomes slightly discoloured. Mr. Guthrie has used it with advantage for penetrating the hard case of new bone which forms over a sequestrum, in order to expose the latter, and permit its convenient extraction.

Chloride of zinc, with a view to its escharotic effect, may be formed extemporaneously by means of *galvanism*, on the plan recommended by an English physician, Dr. Thomas Smith. A simple galvanic circle is formed by riveting a disc of zinc, of the size of the eschar desired, to a disc of silver of equal size; the pair being excited by a piece of spongio-piline, placed on the silver, and moistened with a solution of common salt. The little battery is then fixed upon the skin by means of strips of adhesive plaster. Once in twelve hours it must be removed, and washed in salt and water, and then reapplied. By the electrolysis of the salt, chlorine is liberated, which combines with the zinc, and converts it to a certain extent into the chloride. This, acting on the skin, exercises its caustic effect; and at the end of twelve days a white eschar is formed. This mode of forming an issue has, according to Dr. Smith, the advantage of being less painful than those usually employed.

For internal exhibition, the most convenient form is a solution in the spirit of ether, in the proportion of half an ounce to three fluidounces. Of this from four to eight drops may be given twice a day. Dr. Lloyd, of London, has found chloride of zinc useful as an injection in the acute stage of gonorrhœa, made of the strength of about two grains to three fluidounces of distilled water, and employed once in five or six hours.

In over-doses chloride of zinc acts as a corrosive poison. It produces burning pain in the gullet and stomach, nausea and vomiting, cold sweats, depression of the pulse, and cramps of the legs. According to Dr. T. Stratton, surgeon R. N., who treated two cases of poisoning with this chloride at Montreal, the best antidotes are the carbonated alkalies, which act by converting the poison into carbonate of zinc. In case the alkalies are not at hand, a solution of common soap must be immediately and freely given. (*Med. Exam.*, Feb. 1849, from the *Brit. Am. Journ. of Med. and Phys. Sci.*) Dr. Letheby reports a fatal case of poisoning by this chloride occurring in a child in August 1849. The form of chloride swallowed was Burnett's disinfecting fluid. (See *page* 1282.) Its local effect was that of a corrosive on the lips, mouth, and fauces. Among the constitutional effects were paralysis of the voluntary muscles, coldness of the surface, dilated pupil, and coma. B.

ZINCI CHLORIDI LIQUOR. *Dub.* *Solution of Chloride of Zinc.*

"Take of sheet zinc *one pound* [avoirdupois]; Muriatic Acid of Commerce, Water, of each, *two pints and a half* [Imp. meas.], or *as much as may be sufficient;* Solution of Chlorinated Lime *one fluidounce* [Imp. meas.]; Prepared Chalk *one ounce* [avoird.]. To the zinc, introduced into a porcelain capsule, gradually add the Muriatic Acid, applying heat until the metal is dissolved. Filter the liquid through calico, and, having added to it the Solution of Chlorinated Lime, concentrate at a boiling temperature, until it occupies the bulk of one pint [Imp. meas.]. Permit the solution now to cool down to the temperature of the air, place it in a bottle with the Chalk, and, having first added Distilled Water, so that the bulk of the whole may be a quart [two pints, Imp. meas.], shake the mixture occasionally for twenty-four hours. Finally, filter, and preserve the product in a well stopped bottle. The specific gravity of this liquor is 1·593." *Dub.*

This is a new officinal solution of the Dublin Pharmacopœia of 1850. It is made, in the usual way, by dissolving zinc in muriatic acid. The chlorinated lime is added to the liquid, in order to convert any iron which may be present into sesquichloride, from which it is afterwards precipitated by the chalk. The use of this precipitant introduces into the preparation a small proportion of chloride of calcium, which has no injurious effect. The two pints and a half of water, taken in the formula, are not used in the process. They were probably intended for the dilution of the muriatic acid, which acts better on the zinc when diluted. The preparation is completed by bringing it to a determinate bulk by the addition of distilled water, and by filtration to separate the precipitated iron and any excess of chalk.

Solution of chloride of zinc is a dense, colourless liquid, having a burning nauseous taste even when dilute. It contains 175 grains of zinc in a fluidounce, and has the sp. gr. 1·593. This solution is equivalent to Burnett's disinfecting fluid, noticed below. It is a powerful disinfectant, and, when applied to cancerous and other offensive ulcers, duly diluted with water, destroys their fetor so long as the dressings are kept moist with it. This solution is recommended by M. Gaudriot in gonorrhœa in both sexes, as having remarkable remedial powers. For men he uses an injection, composed of from twenty-four to thirty-six drops in four fluidounces of water. A small quantity only is injected about

an inch up the urethra, two or three times a day. For women he employs a vaginal suppository, formed of five drops of the solution, half a grain of sulphate of morphia, and three drachms of a paste consisting of a drachm and a half of starch, a drachm of mucilage of tragacanth, and half a drachm of sugar. The suppository is introduced every day, or every second day.

Burnett's disinfecting fluid, like the Dublin officinal solution, is an aqueous solution of chloride of zinc. It contains 200 grains of zinc in each Imperial fluidounce, and has the sp. gr. 2. It is, therefore, considerably stronger than the Dublin solution. It is so called after Sir William Burnett, who introduced it into use, in 1840, as a powerful deodorizing and disinfecting agent in neutralizing noxious effluvia, and in arresting animal and vegetable decomposition. Diluted with water it forms Sir William's patent preservative against the dry rot. The concurrent testimony of a number of observers shows that it acts as an excellent disinfectant for ships, hospitals, dissecting rooms, water-closets, privies, &c. (See Extracts from British Navy Reports on chloride of zinc as a disinfectant, in the *Lond. Med. Times and Gaz.*, Oct. 1853, p. 341.) Injected into the blood-vessels, it preserves bodies for dissection, without impairing their colour or texture, and is said not to injure the knives employed; but the accuracy of the latter statement is doubted by some. The advantage is claimed for it, that, while it destroys putrid odours, it has no smell of its own. For preserving anatomical subjects, one part of the disinfecting fluid to eighteen of water will form a solution of the proper strength. For disinfecting purposes on a large scale, a pint of the fluid may be mixed with four gallons of water.

Off. Prep. Zinci Carbonas; Zinci Chloridum. B.

ZINCI OXIDUM. *U. S., Lond. Ed.* Zinci Oxydum. *Dub. Oxide of Zinc.*

"Take of Precipitated Carbonate of Zinc *a pound*. Expose it to a strong heat in a shallow vessel, so as to drive off the carbonic acid." *U. S.*

The *Dublin College* exposes the carbonate in a covered clay crucible to a very low red heat, until a portion of it, taken from the centre, ceases to effervesce on being dropped into dilute sulphuric acid.

"Take of Sulphate of Zinc *a pound;* Sesquicarbonate of ammonia *six ounces and a half;* Distilled Water *three gallons* [Imp. meas.]. Dissolve the Sulphate and Sesquicarbonate, separately, in twelve pints [Imp. meas.] of Water; then mix. Wash the precipitate repeatedly with water, and afterwards expose it for two hours to a strong heat." *Lond.*

The *Edinburgh* formula is essentially the same as the London.

At present all the Pharmacopœias, noticed in this work, prepare the oxide of zinc from the carbonate,—the carbonate ready formed in the U. S. and Dublin formulæ, and made as a step of the London and Edinburgh processes. By referring to the article on precipitated carbonate of zinc, *page* 1278, it will be found that this carbonate is obtained in the U. S. process from sulphate of zinc, in the Dublin from the chloride, in both cases by the decomposing influence of carbonate of soda. In the London and Edinburgh processes the carbonate is obtained extemporaneously from the sulphate of zinc, by means of carbonate of ammonia. Of these methods for forming carbonate of zinc, that of the U. S. Pharmacopœia is to be preferred. M. Lefort found it to furnish a carbonate which is washed with facility, and convertible by calcination into a pure oxide, readily reduced to an impalpable and very light powder. (*Journ. de Pharm.*, 3*e sér.*, xi. 329.) The methods of the British Colleges are ineligible, on account of the comparative cost of the materials employed. The carbonate of zinc, in whatever way obtained, is exposed to heat to drive off the carbonic acid and water, in order to obtain the oxide. According to Mohr, a full red heat is not necessary for this purpose; a temperature between 536° and 572° being sufficient.

Oxide of zinc may be obtained by the combustion of the metal; and in this way it was formerly prepared by the Dublin College. Zinc melts at 773°, and immediately becomes covered with a film of gray oxide. When the temperature reaches nearly to redness, it takes fire and burns with an intense white light, generating the oxide in the form of very light and white flocculi, resembling carded wool, which quickly fill the crucible, and are in part driven into the atmosphere by the current of air. Mr. G. D. Midgley, of London, has recently called attention to the production of oxide of zinc by combustion, and has given a description of the apparatus, by which he is enabled to prepare from one to two hundred weight of the oxide at one operation. It consists of a large muffle, heated to redness in a suitable furnace, and supplied with zinc from time to time as the combustion proceeds. The necessary draught of air is conveyed from the muffle by a tube, passing through the top of the furnace, and terminating in a vessel containing water, in which the portion of oxide carried up by the current is retained. The resulting oxide is freed from particles of metallic zinc by being passed through a sieve. (See *Am. Journ. of Pharm.*, April, 1849.)

Properties, &c. Oxide of zinc is an inodorous, tasteless, white powder, insoluble in water and alcohol. As obtained by the London formula it is yellowish-white. It dissolves readily in acids without effervescence; and in potassa, soda, and ammonia, but not in their carbonates. When heated moderately it beomes yellow; but upon cooling it regains its white colour, unless iron is present, when a yellowish tint remains. At a low white heat it fuses, and at a full white one sublimes. When prepared by combustion, it was formerly called *pompholix*, *nihil album*, *lana philosphica*, and *flowers of zinc*. This oxide is often impure. Much of that sold in the shops effervesces with acids, owing to the presence of carbonate of zinc, or of the carbonate used to precipitate it. Its neutral solution in acids should give a white precipitate with ferrocyanuret of potassium and hydrosulphate of ammonia. If the precipitate with the former test is bluish-white, iron is indicated; if black with the latter, lead is shown. When prepared by the old officinal process, namely, by precipitating sulphate of zinc with caustic ammonia, it contained the subsulphate, the acid of which may be detected by dissolving the oxide in nitric acid, and precipitating by nitrate of baryta. If the oxide contain white lead or chalk, it will not be entirely soluble in dilute sulphuric acid, but an insoluble sulphate of lead or of lime will be left behind. If iron be present, brownish-red flocks of sesquioxide are left undissolved, when the muriatic solution of the oxide of zinc is treated with ammonia in excess. Oxide of zinc consists of one eq. of zinc 32·3, and one of oxygen 8=40·3.

Medical Properties and Uses. Oxide of zinc is tonic and antispasmodic. It has been given in chorea, epilepsy, hooping-cough, spasm of the stomach dependent on dyspepsia, and other similar affections. Externally, it is employed as an exsiccant to excoriated surfaces, sometimes by sprinkling it on the affected part, but generally in the form of ointment. (See *Unguentum Zinci Oxidi.*) The dose is from two to eight grains or more, repeated several times a day, and given in the form of pill.

Oxide of zinc is extensively used at present (1854) in painting, as a substitute for white lead, over which it has the advantage of not being discoloured by sulphuretted hydrogen. It has, moreover, the merit of not producing injurious effects on the workmen, at all comparable to those caused by white lead.

Off. Prep. Unguentum Zinci Oxidi. B.

ZINCI SULPHAS. *U.S., Lond., Ed., Dub. Sulphate of Zinc. White Vitriol.*

"Take of Zinc, in small pieces, *four ounces;* Sulphuric Acid *six ounces;* Distilled Water *four pints.* To the Zinc and Water, previously introduced into a

glass vessel, add by degrees the Sulphuric Acid, and, when the effervescence has ceased, filter the solution through paper; then boil it down till a pellicle begins to form, and set it aside to crystallize." *U. S.*

In the *London* Pharmacopœia of 1851, this salt has been transferred to the list of Materia Medica.

"This salt may be prepared either by dissolving fragments of Zinc in Diluted Sulphuric Acid till a neutral liquid be obtained, filtering the solution, and concentrating sufficiently for it to crystallize on cooling—or by repeatedly dissolving and crystallizing the impure Sulphate of Zinc of commerce, until the product when dissolved in water does not yield a black precipitate with tincture of galls, and corresponds with the characters laid down for Sulphate of Zinc in the list of the Materia Medica." *Ed.*

"Take of Zinc, laminated, or in small fragments, *four ounces* [avoirdupois]; Oil of Vitriol of Commerce *three fluidounces* [Imp. meas.]; Distilled Water *one quart* [two pints, Imp. meas.]; Nitric Acid of Commerce, Dilute Sulphuric Acid, of each, *a fluidrachm* [Imp. meas.]; Prepared Chalk *two drachms* [Dub. weight]. Place the Zinc, Oil of Vitriol, and a pint of the Water in a porcelain capsule, and, when gas ceases to be developed, boil for ten minutes. Pass then the solution through a calico filter, and, having added to it the Nitric Acid, evaporate to dryness. Let the dry salt be dissolved in the remainder of the Water, and let the solution when cold be shaken several times for six hours in a bottle with the Chalk, and then cleared by passing it through a filter. It is now, after having been acidulated with the Dilute Sulphuric Acid, to be evaporated till a pellicle begins to form on its surface, and then set to crystallize. The crystals thus obtained should be dried on blotting-paper without heat, and then preserved in a bottle. By further concentrating the solution from which the crystals have been separated, an additional product will be obtained." *Dub.*

By these processes crystallized sulphate of zinc is obtained. *Strong* sulphuric acid has very little action on zinc; but, when it is *diluted*, water is instantly decomposed, and, while its hydrogen escapes with rapid effervescence, its oxygen combines with the zinc; and the oxide formed, uniting with the acid, generates the sulphate of the oxide of zinc. Thus it is perceived that *hydrogen* is a collateral product of the process. The proportion of the zinc to the strong acid is as 4 to 6 in the U. S. process, and as 4 to 5·53 in the Dublin. The equivalent numbers give the ratio of 4 to 6·06; which indicates that the U. S. numbers approach very nearly to the true proportion. If the materials be mixed at once, without any precaution, the effervescence of hydrogen is apt to be excessive, and to cause the overflowing of the liquid. This is avoided by the direction of the U. S. formula, to commence the solution of zinc with a very dilute acid, which, as the action slackens, is made by degrees stronger and stronger, by the addition, at intervals, of small portions of fresh acid. The formula of the Ed. Pharmacopœia embraces directions for obtaining the salt either by direct combination, or by purifying the white vitriol of commerce from iron by repeated crystallizations. The Dublin formula is peculiar in using a little nitric acid and prepared chalk. The acid has the effect of sesquioxidizing any iron which may be present, and the chalk of precipitating it. The boiling and evaporation to dryness have the effect of producing a portion of basic sulphate of zinc, which is converted into neutral sulphate before crystallizing by the addition of a little dilute sulphuric acid.

Preparation on the Large Scale. Impure sulphate of zinc, as it occurs in commerce, is called *white vitriol*. It is manufactured by roasting *blende* (native sulphuret of zinc) in a reverberatory furnace. This mineral, besides sulphuret of zinc, contains small quantities of the sulphurets of iron, copper, and lead; and by roasting is converted, in consequence of the oxidation of its constituents,

into sulphate of zinc, mixed with the sulphates of iron, copper, and lead. The roasted matter is then lixiviated; and the solution obtained, after having been allowed to settle, is concentrated by evaporation; so that, on cooling, it may concrete into a white crystalline mass, resembling lump sugar. In this state it always contains sulphate of iron, and sometimes a small portion of sulphate of copper. It may be purified from these metals by dissolving it in water, and boiling the solution with oxide of zinc, which converts the sulphates of iron and copper, by precipitating their bases, into sulphate of zinc. The purified solution is then decanted or filtered, and, after due evaporation, allowed to crystallize. It has generally been proposed to purify the white vitriol of commerce by digesting its solution with metallic zinc, under the impression that this is capable of precipitating all the foreign metals; but, according to Berzelius, though it will precipitate copper readily, it has no action on iron.

Properties, &c. Sulphate of zinc is a colourless, transparent salt, having a disagreeable, metallic, styptic taste, and crystallizing usually in small four-sided prisms. Its crystals have considerable resemblance to those of sulphate of magnesia. It effloresces slightly in dry air, and, though neutral in composition, is still capable of reddening vegetable blues. It dissolves in two and a half times its weight of cold water, and in less than its weight of boiling water, and is insoluble in alcohol. When heated, it dissolves in its water of crystallization, which gradually evaporates; and, by a prolonged ignition, the whole of the acid is expelled, and the oxide of zinc left. Potassa, soda, and ammonia throw down a white precipitate of mixed oxide and subsulphate, which is redissolved by the alkali when added in excess. If iron be present it is precipitated also, but not redissolved. The alkaline carbonates precipitate the metal in the state of white carbonate. Pure sulphate of zinc is precipitated white by ferrocyanuret of potassium and hydrosulphate of ammonia. What is thrown down by chloride of barium or acetate of lead (sulphate of baryta or sulphate of lead) is not dissolved by nitric acid. The precipitate thrown down from a solution of 100 grains of the salt by carbonate of ammonia yields, after exposure to a strong heat, 27·9 grains of oxide of zinc. (*Lond. Pharm.*) If copper be present, ammonia will produce a blue tinge; if iron, the ferrocyanuret of potassium will cause a bluish-white precipitate instead of a white one. Cadmium and arsenic may be detected by acidulating the solution with sulphuric acid, and passing a stream of sulphuretted hydrogen through it; when, if either of these metals be present, it will be thrown down as a yellow sulphuret. Sulphate of zinc is incompatible with alkalies and alkaline carbonates, hydrosulphates, lime-water, the soluble salts of lead, and astringent infusions.

The impure commercial variety of sulphate of zinc, called white vitriol, is in the form of irregular white masses, having some resemblance to lump sugar. The lumps usually exhibit, here and there on the surface, yellow stains, produced by the sesquioxide of iron. It is less soluble than the pure salt, on account of its containing less water of crystallization.

Composition. Crystallized sulphate of zinc consists of one eq. of sulphuric acid 40, one of oxide of zinc 40·3, and seven of water 63=143·3. The white vitriol of commerce contains but three eqs. of water.

Medical Properties and Uses. This salt is tonic, astringent, and, in large doses, a prompt emetic. As a tonic, it is supposed to be well suited to cases of debility, attended with irritation, being less heating than sulphate of iron. In dyspepsia it has been used with advantage in very minute doses, as, for instance, a quarter of a grain, repeated several times a day; but if its good effects are not soon apparent, it should be laid aside. In obstinate intermittents, it is a valuable resource, and may be given alone or conjoined with cinchona or sulphate of quinia. But it is in spasmodic diseases, such as epilepsy, chorea, pertussis, &c., that it

has been principally employed. Dr. Paris speaks of its efficacy in high terms, in spasmodic cough, especially when combined with camphor or myrrh, and "in affections of the chest attended with inordinate secretion." As an astringent it is chiefly employed externally. In this mode of application, its solution constitutes a good styptic to bleeding surfaces, and is frequently resorted to as an injection in fluor albus and the advanced stages of gonorrhœa, and as a collyrium in ophthalmia. In some conditions of ulcerated sorethroat, it forms a useful gargle. It has been employed also in solution with success as a remedy for nasal polypi, in the proportion of two scruples, gradually increased to an ounce of the salt, to seven fluidounces of water, applied by means of lint and by injection. Before the discovery of tartar emetic, sulphate of zinc was almost exclusively employed to produce vomiting; but at present its use as an emetic is restricted principally to the dislodging of poisons, for which purpose its property of operating rapidly renders it particularly suitable. The dose, as a tonic, is from one to two grains; as an emetic, from ten to thirty grains. To children affected with hooping-cough, it may be given in doses of from an eighth to a quarter of a grain two or three times a day. When used as a collyrium, injection, or gargle, or as a wash for indolent ulcers, from one to three grains, or more may be dissolved in a fluidounce of water. For medical purposes the crystallized salt should be used, and in no case the impure white vitriol of commerce.

Sulphate of zinc, in an over-dose, acts as an irritant poison. Besides vomiting and incessant retching, there are produced anxiety, distressing restlessness, and extreme prostration. Few cases are on record of fatal poisoning by this salt; the patient being generally relieved by a prompt expulsion of the poison by vomiting. Four cases, however, have been latterly reported in an Italian journal, two of which were fatal. In one of the fatal cases, an ounce and a half had been swallowed by mistake for Epsom salt. The proper treatment consists in the administration of large quantities of bland drinks, the use of opium to allay irritation, and the employment of the usual antiphlogistic remedies, in case symptoms of inflammation should arise.

Off. Prep. Liquor Aluminis Compositus; Zinci Carbonas Præcipitatus; Zinci Oxidum; Zinci Valerianas. B.

ZINCI VALERIANAS. *Dub. Valerianate of Zinc.*

"Take of Valerianate of Soda *two ounces and a half* [avoirdupois]; Sulphate of Zinc *two ounces and seven drachms* [avoird.]; Distilled Water *one quart* [two pints, Imp. meas.]. Dissolve the Valerianate of Soda in one-half, and the Sulphate of Zinc in the remaining half of the Water, and, having raised both solutions to 200°, mix them, and skim off the crystals which are produced. Let the solution be now evaporated at a temperature not exceeding 200°, until it is reduced to the bulk of four [fluid]ounces, removing, as before, the crystals from the surface, in proportion as they form, and placing them with those already obtained. The salt thus procured is to be steeped for an hour in as much cold distilled water as is just sufficient to cover it, and then transferred to a paper filter, on which it is to be first drained, and then dried at a heat not exceeding 100°." *Dub.*

In the formation of this new officinal of the Dublin Pharmacopœia of 1850, a double decomposition takes place between the reacting salts, resulting in the production of sulphate of soda and valerianate of zinc. Upon mixing the hot solutions, crystals of the sparingly soluble valerianate of zinc form on the surface of the liquid; and, during the progress of its concentration to one-tenth, more of them are successively produced. These are then washed with cold distilled water to separate adhering sulphate of soda, drained on a filter, and dried.

Properties. This salt is in white, pearly scales, which have a faint odour of valerianic acid, and an astringent, metallic taste. It dissolves in 160 parts of

cold water, and in 60 of alcohol, of the sp. gr. 0·833. The solutions, which have an acid reaction, become turbid on the application of heat, but clear again on cooling. The salt, as obtained by the Dublin formula, is anhydrous; but, when formed by exactly saturating carbonate of zinc, made into a paste with water, with valerianic acid, it contains twelve eqs. of water, and, when dried at 122°, perfectly resembles the anhydrous salt. (*G. C. Wittstein.*) Sometimes acetate of zinc, impregnated with oil of valerian, is fraudulently substituted for this salt. The butyrate of zinc has been sold in Paris for the valerianate, and is so similar to the latter as not to be distinguished by its physical properties. The two salts, however, may be chemically discriminated, by adding a concentrated solution of the acid of the suspected salt, obtained by distillation with sulphuric acid, to a concentrated solution of acetate of copper. If the acid be the butyric, its addition to the solution of the acetate disturbs the transparency of the latter, by the formation of a bluish-white precipitate; while, if it be the valerianic, no change is produced. (Larocque and Huraut, *Journ. de Pharm.*, 3*e sér.*, ix. 430.)

Medical Properties. Valerianate of zinc was proposed as a remedy, on theoretical grounds, by Prince Louis-Lucien Bonaparte. Upon trial it was found to possess antispasmodic properties. By some of the Italian physicians it has been extolled as a remedy in neuralgic affections. Dr. Namias, of Venice, employed it with advantage in anomalous nervous affections, attended with palpitation of the heart, constriction of the throat, and pain in the head. Dr. Francis Devay, of Lyons, found it useful in epilepsy, and in the nervous affections which accompany chlorosis. The dose is one or two grains, repeated several times a day, and given in the form of pill. (See a paper on this valerianate by Prof. Procter, in the *Am. Journ. of Pharm.*, for April, 1845.) B.

APPENDIX.

I. DRUGS AND MEDICINES NOT OFFICINAL.*

In the progress of the medical art, numerous remedies have at different times risen into notice and employment, which, by the revolutions of opinion incident to our science, or by the discovery of more efficient substitutes, have so far fallen into disrepute as to have been discarded from general practice, and no longer to hold a place in the officinal catalogues. Of these, however, some are still occasionally employed by practitioners and referred to by writers, and may retain a popularity as domestic remedies, or among empirics, which they have lost with the medical profession generally. The attention of physicians must, therefore, frequently be called to them in the course of practice; and it is highly desirable to possess some knowledge of their properties and effects, in order to be enabled to judge of their agency in any particular case, and at the same time to avoid the suspicion of incompetence which might attach to the exhibition of entire ignorance in relation to them. The remark is true also of other substances, which, though at no time ranked among regular medicines, are yet habitually employed in families, and the influence of which, either remediate or otherwise, must often enter into our estimate of the causes which produce or modify disease. New medicines, moreover, are frequently brought forward, which, without having obtained the sanction of the medical authorities, are occasionally prescribed, and therefore merit notice. To supply, to a certain extent, the requisite means of information in regard to these extra-officinal remedies, is the object of the following brief notices, among which are also included accounts of substances not employed as medicines, but usually kept in the drug stores for various purposes connected with the arts, or with domestic convenience. In a work intended for the use as well of the apothecary and druggist, as of the physician and medical student, the introduction of such accounts is obviously proper, if kept in due subordination to the more important object of teaching the properties of medicines, and the modes of preparing them. The authors regret that the limits which practical convenience appears to require in a Dispensatory, do not admit of a more complete enumeration of the various drugs and medicines of the kind above alluded to, or of ampler details in relation to those actually treated of, than will be found in the following pages. They have endeavoured, however, in the selection of objects, to choose those which are likely most frequently to engage the attention of the medical and pharmaceutical professions, and, in the extent of the descriptions, to consult as far as possible the relative importance of facts, of which they could not detail the whole. In relation to the nomenclature employed, it may be proper to observe that all those vegetable remedies, which, not being generally kept in the shops, have no current commercial name, are described under the scientific title of the plant producing them; while other substances are designated by the names which ordinary usage has assigned them.

* By the term officinal medicines, here as well as elsewhere in this work, are meant such as are embraced in the United States and British Pharmacopœias.

ACETATE OF COPPER. *Cupri Acetas. Crystals of Venus.* This salt is prepared by dissolving verdigris, with the assistance of heat, in vinegar or dilute acetic acid. The solution, after having been sufficiently concentrated, is transferred to suitable vessels, where it crystallizes on cooling. Acetate of copper is a slightly efflorescent salt, crystallizing in rhomboidal prisms, and having a rich deep-blue colour and strong styptic taste. It dissolves in water without residue, a character which serves to distinguish it from verdigris. It consists of one eq. of acetic acid, one of protoxide of copper, and one of water. Its popular name of *distilled verdigris* is inappropriate; as no distillation is practised in its preparation. This salt is used for colouring maps. It was formerly the chief source of acetic acid. It has no medical uses, and has been very properly abandoned by the Dublin College as an officinal preparation in its Pharmacopœia of 1850.

ACETATE OF MAGNESIA. *Magnesiæ Acetas.* This salt has been proposed as a purgative by M. Renault, of Paris. It has the merit of extreme solubility both in water and alcohol. Though without much taste, it is inferior in that respect to citrate of magnesia, for which it is proposed as a substitute. It is prepared for therapeutic use by saturating 120 parts of carbonate of magnesia with acetic acid, and evaporating the resulting liquid, after filtration, to 300 parts. The product is a syrupy acetate of magnesia, which is to be mixed with three times its weight of syrup of oranges, to form the preparation of M. Renault. Of this about four ounces is the dose. The objection to this liquid acetate of magnesia is, that, owing to its attraction for moisture, it cannot be preserved of uniform strength for mixing with the syrup of oranges. (*Journ. de Pharm.*, *3e sér.*, xiii. 260.)

ACETIC ETHER. *Æther Aceticus.* This ether may be formed by several processes, the chief of which are the following:—1. Mix 100 parts of alcohol (sp. gr. 0·83) with 63 parts of concentrated acetic acid, and 17 parts of strong sulphuric acid, and distil 125 parts into a receiver, kept cold with wet cloths. 2. Distil to dryness, a mixture of 3 parts of acetate of potassa, 3 of alcohol, and 2 of sulphuric acid, and mix the distilled product with one-fifth of sulphuric acid, and distil a second time an amount of ether equal to the alcohol employed. 3. Distil 2 parts of effloresced acetate of lead with 1 part of alcohol, and a little more than 1 part of sulphuric acid. In the last two processes, the acetic acid is set free by the action of the sulphuric acid on the acetate employed. Acetic ether is colourless, of a very grateful odour, and a peculiar, agreeable taste. Its specific gravity is 0·866, and its boiling point 160°. It undergoes no change by being kept. By contact of flame it burns readily, diffusing an acid odour. It dissolves in seven and a half parts of water, and unites in all proportions with alcohol. It consists of one eq. of acetic acid 51, and one of oxide of ethyle (ether) 37=88 ($C_4H_5O,C_4H_3O_3$).

Acetic ether is occasionally used in medicine as a stimulant and antispasmodic. The dose is from fifteen to thirty drops, sufficiently diluted with water. It is sometimes employed externally, by friction, as a resolvent, and for rheumatic pains.

ACHILLEA MILLEFOLIUM. *Milfoil. Yarrow.* This is a perennial herb, common to the old and new continents, though supposed to have been introduced into this country from Europe. It abounds in old fields, along fences, and on the borders of woods and of cultivated grounds, throughout the United States. It is from a foot to eighteen inches high, and is distinguished by its doubly pinnate minutely divided leaves, from which it derived the name of milfoil, and by its dense corymb of whitish flowers, which appear throughout the summer, from June to September. The whole herb is medicinal. Both the flowers and leaves have an agreeable, though feeble aromatic odour, which continues after drying, and a bitterish, astringent, pungent taste. The aromatic properties are strongest in the flowers, the astringency in the leaves. The plant owes its virtues to a volatile oil, a bitter extractive, and tannin. It contains also a peculiar acid, denominated *achilleic acid.* The oil, which may be obtained separate by distillation with water, has a beautiful azure-blue colour, and the peculiar flavour of milfoil. The active principles are extracted both by water and alcohol. The medical properties of the herb are those of a mild aromatic tonic and astringent. In former times it was much used as a vulnerary, and was also given internally for the suppression of hemorrhages, and of profuse mucous discharges. It has been recommended in intermittents, and as an antispasmodic in flatulent colic, and nervous affections; but is at present little used. It has recently been highly recommended by M. Richart, of Soissons, in low forms of exanthematous fevers with difficult eruption, in colic, painful menstruation, and infantile convulsions. He uses the infusion at once as a drink, an injection, and fomentation. (See *Journ. de Pharm. et de Chim.*, xviii. 62.) In some parts of Sweden it is said to be employed as a substitute for hops in the preparation of beer, which it is thought to render more intoxicating. It is most conveniently administered in the form of infusion. The volatile oil has been given in the dose of twenty or thirty drops.

ACTÆA SPICATA. *Baneberry. Herb Christopher.* This is a perennial, herbaceous, European plant, growing in the woods of mountainous regions, and attaining a height of two feet or more. The root is of a dark-brown colour, and bears some resemblance to that of Helleborus niger, for which it is said to be occasionally substituted. Its odour, in the recent state, is sweetish and rather nauseous, but is in great measure dissipated by drying. The taste is bitterish, and somewhat acrid. In its operation on the system, the root is purgative and sometimes emetic, and is capable, in over-doses, of producing dangerous effects. It is unknown in this country. We have, however, a native species of Actæa—*A. Americana* of Pursh—of which there are two varieties—*alba* and *rubra*—distinguished by the colour of their berries, which in the former are white, and in the latter red. They are sometimes called *white* and *red cohosh*, a name derived from the language of the Aborigines. By some botanists they are treated of as distinct species, under the names of *Actæa alba*, and *Actæa rubra*. They grow in the rich deep mould of shady and rocky woods, from Canada to Virginia. They are said to have been much esteemed by the Indians. Their medical properties are probably similar to those of the *A. spicata*. The name *baneberry*, given to different species of Actæa, was derived from the reputed poisonous properties of their berries.

ADANSONIA DIGITATA. *Baobab.* A tree of enormous magnitude, belonging to the Linnæan class and order Monadelphia Polyandria, and to the natural family Sterculiaceæ (Lindley). It is a native of Africa, extending quite through that continent from Senegal to Abyssinia, and has been introduced into the West Indies. The leaves and bark of this tree abound in mucilage, and have little smell or taste; yet extraordinary virtues have been ascribed to them. Adanson found the leaves very useful as a preventive of fevers, and they are employed habitually by the native Africans with a view to their diaphoretic property. Dr. Duchassaing, of Guadaloupe, has published a statement of his experience with the bark in the miasmatic diseases of the West Indies. Out of 93 cases, chiefly of intermittent fever, he failed only in three. M. Pierre has subsequently employed the remedy with success in intermittent fever at Bourgogne, in France. (*Arch. Gén. de Med.*, 3e *sér.*, xxiii. 535.) The bark has the advantage over cinchona of being almost without taste, and quite acceptable to the stomach. It produces no other observable physiological effect than some increase of appetite, increased perspiration, and perhaps diminished frequency of the pulse. An ounce may be boiled in a pint and a half of water to a pint, and the whole taken in a day. (*Journ. de Pharm.* 3e *sér.*, xiii. 412 and 421.) The fruit, which contains a subacid not disagreeable pulp, is used by the Africans in dysentery and other bowel complaints.

ADIANTUM PEDATUM. *Maidenhair.* An indigenous fern, the leaves of which are bitterish and aromatic, and have been supposed to be useful in chronic catarrhs and other pectoral affections. A European species, known by the same vulgar name, is the *A. Capillus Veneris*, which has similar properties, though feebler, and has been much used as a pectoral, on the continent of Europe, from very early times. It is given in the form of infusion, sweetened with sugar or honey; and a syrup prepared from it is popular in France, under the name of *sirop de capillaire*. The name of maidenhair has also been given to *Asplenium Trichomanes*, the leaves of which have a mucilaginous, sweetish, somewhat astringent taste, and have been used for the same purposes with those of the plants above mentioned. Another species of Asplenium, *A. Adiantum nigrum*, has been substituted for the genuine maidenhair; but neither of them has the aromatic flavour of that fern.

ÆSCULUS HIPPOCASTANUM. *Horsechestnut.* The horsechestnut is a native of Asia, and was introduced about the middle of the sixteenth century into Europe, where, as well as in this country, it is now extensively cultivated as an ornamental tree. The fruit and bark have been used in medicine. The *fruit* abounds in starch, but has a rough, disagreeable, bitter taste, which renders it unfit for food, though it is said to be eaten with avidity by horses, oxen, hogs, and sheep. It may be deprived, in great measure, of the bitter principle by maceration in an alkaline solution. It is asserted that the starch may be readily obtained in a state of purity, and that it excels as an article of diet that procured from the potato. (*Dict. de Mat. Med.*) The bitter principle is denominated *esculin*, and, according to Rochleder, may be obtained by precipitating with acetate of lead a decoction of the rind, filtering, treating the filtered liquor with sulphuretted hydrogen, again filtering, evaporating to the consistence of syrup, and setting the residue aside in a cool place. In a few days, the liquid is converted into a mass of crystals, which are to be expressed, and purified by repeated crystallization from alcohol, and afterwards from boiling water. If now washed on a filter with cold water till they have lost one-third of their weight, they are rendered as pure as it is possible to obtain them. Esculin is in shining white prismatic crystals, inodorous, bitter, but slightly soluble in cold water, more soluble in boiling water, and very readily so in boiling alcohol, and in alkaline solutions. Its solution is precipitated by subacetate of lead. It consists of carbon, hydro-

gen, and oxygen. (See *Journ. de Pharm.*, 3e *sér.*, xxiii. 474, and xxiv. 292.) The powdered kernel of the fruit, snuffed up the nostrils, produces sneezing, and has been used with advantage as a sternutatory in complaints of the head and eyes. The *bark* of the horsechestnut has attracted much attention on the continent of Europe, as a substitute for cinchona. That of the branches from three to five years old is considered best. It should be collected in the spring. It has little odour, but an astringent and bitter, though not very disagreeable taste. It contains, among other ingredients, bitter extractive and tannin, and imparts its virtues to boiling water. By numerous physicians it has been found very efficacious in the treatment of intermittent fever; but it has entirely failed in the hands of many others, and certainly cannot be considered comparable to the Peruvian bark in its power over that complaint. It is at present seldom used, and never in this country. It has been given in substance, decoction, and extract. From half an ounce to an ounce of the powder may be given in the course of twenty-four hours. The decoction is prepared and administered in the same manner as that of Peruvian bark.

AGARIC. *Touchwood. Spunk. Tinder.* This is the product of different species of a genus of mushrooms denominated *Boletus*. Several species are used as food, several are poisonous, and two at least have been ranked among officinal medicines in Europe. The *Boletus laricis* which grows upon the larch of the old world, is the *white agaric* or *purging agaric* of medical writers. It is of various sizes, from that of the fist to that of a child's head, or even larger, hard and spongy, externally brownish or reddish; but, as found in commerce, is deprived of its exterior coat, and consists of a light, white, spongy, somewhat farinaceous, friable mass, which, though capable of being rubbed into powder upon a sieve, is not easily pulverized in the ordinary mode, as it flattens under the pestle. It has a sweetish very bitter taste, and consists, according to Braconnot, of 72 parts of resinous matter, 2 of bitter extractive, and 26 of *fungin*, a nutritious animalized principle, constituting the base of the fleshy substance of mushrooms. It contains also benzoic acid and various saline compounds. In the dose of four or six grains it is said to act powerfully as a cathartic; but Lieutaud asserts that it may be given in the quantity of thirty grains or a drachm without sensibly purging. M. Andral has found it useful in checking the night-sweats of phthisis. He uses it in doses of eight grains, and gradually increases to a drachm during the day, without any observable inconvenience to the digestive functions. In this country it is scarcely employed, though we have met with it in the shops. That which is most esteemed is said to be brought from Siberia; but it is probably produced wherever the European larch grows. Dr. Wm. M. McPheeters has published, in the *St. Louis Med. and Surg. Journ.* (x. 421), an account of several cases, in which he tried a specimen of Boletus laricis, brought from the Rocky Mountains, in almost all of which it proved decidedly cathartic. The dose was 25 grains, which it was sometimes necessary to repeat.

The Boletus igniarius, or *agaric of the oak*, like the species just described, is compared in shape to the horse's hoof. Its diameter is from six to ten inches. It is soft like velvet when young, but afterwards becomes hard and ligneous. It usually rests immediately upon the bark of the tree, without any supporting footstalk. On the upper surface it is smooth, but marked with circular ridges of different colours, more or less brown or blackish; on the under, it is whitish or yellowish, and full of small pores; internally it is fibrous, tough, and of a tawny-brown colour. It is composed of short tubular fibres compactly arranged in layers, one of which is added every year. The best is that which grows on the oak, and the season for collecting it is August or September. It has neither taste nor smell. Among its constituents, according to Bouillon-Lagrange, are extractive, resin in very small proportion, azotized matter also in small quantity, chloride of potassium, and sulphate of lime; and in its ashes are found iron, and phosphate of lime and magnesia. It is prepared for use by removing the exterior rind or bark, cutting the inner part into thin slices, and beating these with a hammer until they become soft, pliable, and easily torn by the fingers. In this state it was formerly much used by surgeons for arresting hemorrhage, being applied immediately, with pressure, to the bleeding vessel. It probably acts mechanically, like any other soft porous substance, by absorbing the blood and causing it to coagulate, and is not relied on in severe cases. In the obstinate hemorrhage which occasionally takes place from leech bites, especially those of the European leech, it may be used advantageously, though perhaps not more so than well-prepared lint. It has been sometimes applied to the purposes of moxa.

When prepared agaric is steeped in a solution of nitre, and afterwards dried, it becomes very readily inflammable, and is employed as tinder. Some recommend the substitution of chlorate of potassa for nitre. The preparation is usually known by the name of *spunk*, and is brought to us from Europe. Spunk or tinder, the *amadou* of the French, is in flat pieces, of a consistence somewhat like that of very soft rotten buckskin leather,

of a brownish-yellow colour, capable of absorbing liquids, and inflammable by the slightest spark. It is said to be prepared from various other species of Boletus, as *B. ungulatus, B fomentarius, B. ribis, &c.*

AGAVE AMERICANA. *American Agave. American Aloe. Maguey.* An evergreen succulent plant, indigenous in Florida, Mexico, and other parts of tropical America. This and other species of Agave bear a considerable resemblance, in appearance, to the plants of the genus Aloe, with which they are sometimes confounded. From the root and leaves of the American agave, when cut, a saccharine juice flows out, which may be converted by evaporation into syrup and even sugar, and by fermentation into a vinous liquor. According to M. Lenoble, this juice when fresh has an herbaceous somewhat nauseous odour and acrid taste, and reddens litmus paper. It is said to be laxative, diuretic, and emmenagogue. Dr. G. Perin, assistant surgeon in the U. S. army, has found the juice an admirable remedy in scurvy, being more prompt and efficacious even than lime-juice. He gave two fluidounces three times a day. (*N. Y. Journ. of Med.*, N. S., vii. 181.) The expressed juice, evaporated to the consistence of a soft extract, has the property of forming a lather with water, and is employed in some places as a substitute for soap. The fibres of the old leaves, separated by bruising and maceration in water, are used for forming thread. M. Lenoble found in the leaves an acrid volatile oil, a gum-resinous principle, lignin, salts of potassa and lime, and silica: and thinks that a vinegar or ointment of the leaves might be advantageously used as an epispastic application. (*Journ. de Pharm. et de Chim.*, xv. 350.) The *Agave Virginica*, which grows in our Southern States, and is known in South Carolina by the name of *rattlesnake's master*, has a very bitter root, which is used in the form of tincture, in flatulent colic, and as a counter-poison in the bites of serpents. (Robert King Reid, *Inaug. Thes.*, A. D. 1849.)

AGRIMONIA EUPATORIA. *Common Agrimony.* This species of agrimony is a perennial herb, inhabiting Asia, Europe, and North America, and in this country, found in fields and on the borders of woods, and flowering during the summer months. Its stem, which rises from one to three feet in height, is hairy, furnished with interruptedly pinnate leaves, and terminated by a long simple spike of yellow flowers. Both the herb and root have been employed. The former has a weak but agreeable aromatic odour, and a rough, bitterish, somewhat aromatic taste. The fragrance is strongest in the flowers. The root has similar properties; but its taste is more bitter and astringent. A volatile oil may be obtained from the plant by distillation. Agrimony is a mild corroborant and astringent. The herb has been employed in relaxed conditions of disease, as in passive hemorrhages, and chronic affections of the mucous membranes. It has been recommended, also, as a deobstruent in jaundice and visceral obstructions, and as an alterative in diseases of the skin. In Europe it is popularly used, in the form of gargle, in affections of the throat. The Indians of North America and the Canadians are reported to have employed the root with advantage in fevers. The plant may be given in substance, infusion, or decoction. The dose of the powder is a drachm or more.

AJUGA CHAMÆPITYS. *Ground Pine. Chamæpitys.* A low, creeping, annual, labiate plant, a native of Europe, and found also in some parts of the United States. The leaves, which bear some resemblance to those of the pine in shape, have a strong, peculiar, resinous, not disagreeable odour, and a bitter, balsamic taste. They yield by distillation with water a small proportion of volatile oil, resembling that of turpentine. They are said to be stimulant, diuretic, and aperient; and have been given in rheumatism, gout, palsy, and amenorrhœa. The dose of the leaves in powder is one or two drachms; but their infusion in wine is considered the best preparation.

The *Ajuga reptans* or *common bugle*, and the *A. pyramidalis*, perennial plants of Europe, have also been used in medicine. They are nearly inodorous, but have a somewhat astringent, bitterish, and saline taste. Their virtues are probably those of a mild astringent and tonic. They have been recommended in pulmonary consumption, hæmoptysis and other hemorrhages, and in hepatic obstructions, and have enjoyed considerable reputation as vulneraries; but they are at present nearly obsolete.

ALBUMINATE OF IRON AND POTASSA, SYRUP OF. This syrup, proposed by M. Lassaigne, is made as follows.—Dissolve 100 parts of the white of eggs in 100 of distilled water, and precipitate the filtered solution with 36 parts of a solution of the sulphate of sesquioxide of iron, marking 5° of the areometer. Then add 2 parts of alcoholic potassa, previously dissolved in 50 parts of water. This, by agitation, will gradually dissolve the precipitate caused by the ferruginous solution, forming a deep orange-yellow liquid. The liquid is then converted into a syrup by dissolving in it one and a half times its weight of coarsely powdered sugar, and filtered. The syrup has a slightly alkaline and sweetish taste, totally devoid of inky flavour. Each fluidounce contains about six grains of anhydrous sesquioxide of iron. Mr. A. J. Cooley has proposed to make a simple *albuminate*

of iron, by dissolving the freshly precipitated oxides of iron in a filtered solution of albumen.

ALCHEMILLA VULGARIS. *Ladies' Mantle.* A perennial European herb, growing in meadows, on the banks of rivulets, and in the borders of woods. The whole plant has an astringent bitterish taste, which is strongest in the root. It was formerly employed in diarrhœa, and other complaints requiring the use of astringents. By the ancients it was highly esteemed; and extraordinary powers were ascribed to it by the alchemists, from whom, according to Linnæus, it derived its generic title.

ALCORNOQUE. Under this name, a bark was introduced into Europe from South America, more than fifty years since, and for a short time attracted considerable attention. It has been conjecturally referred by different writers to different plants, but its precise origin is unknown. It is in large thick pieces, composed of two layers, of which the external is reddish, cracked, granular, spongy, and two or three lines in thickness, the internal lamellated, woody, and possessed of the property of imparting a yellow colour to the saliva when chewed. It is inodorous. The outer layer is of an astringent, somewhat bitter taste, and was thought to have febrifuge powers; the inner is much more bitter, and is decidedly emetic. The bark was brought into notice chiefly as a remedy in phthisis; but, having been found useless in that complaint, has fallen into entire neglect. It was given in the form of powder, in the dose of thirty grains; or half an ounce of it was boiled in a pint of water down to half a pint, and two or three tablespoonfuls of the decoction were administered every two hours. In these doses it acted as an emetic. The bark known in Spain by the name of *alcornoque* is derived from the cork tree (Quercus Suber), and has sometimes been confounded in European pharmacy with that derived from South America. It has the properties of the ordinary oak barks.

ALISMA PLANTAGO. *Water Plantain.* A perennial herbaceous plant, common to Europe and the United States, and growing in streams, pools, ditches, and other standing waters. The *root* has when fresh an odour like that of Florentine orris, but loses it when dried. Its taste is acrid and nauseous. It acquired at one time considerable credit as a preventive of hydrophobia, for which purpose it was said to have been used with great advantage in Russia; but subsequent experiments have proved its total inefficacy. The Calmucks are said to use it for food. The *leaves* are rubefacient, and will sometimes even blister when applied to the skin. They have been recommended in gravel and complaints of the bladder, in the dose of a drachm.

ALKANET. This is the root of *Anchusa tinctoria* or *dyers' alkanet*, an herbaceous perennial plant, growing in the Grecian Archipelago and the South of Europe. It is said in some medical works to be cultivated abundantly in the South of France; but another plant is probably referred to—the *Lithospermum tinctorium* of Linnæus and De Candolle, the *Anchusa tinctoria* of Lamarck—which is a native of that country, and the root of which is considered as the true alkanet by the French writers. Alkanet, as found in the shops, is in pieces three or four inches long, from the thickness of a quill to that of the little finger, somewhat twisted, consisting of a dark-red, easily separable bark, and an internal ligneous portion, which is reddish externally, whitish near the centre, and composed of numerous distinct, slender, cohering fibres. As it comes to us it is usually much decayed internally, very light, and of a loose almost spongy texture. The fresh root has a faint odour, and a bitterish astringent taste; but when dried it is nearly inodorous and insipid. Its colouring principle, which abounds most in the cortical part, is soluble in alcohol, ether, and the oils, to which it imparts a fine deep red; but is insoluble in water. It may be obtained by first exhausting the root with water, and then treating it with a weak solution of the carbonate of potassa or soda, from which the colouring principle may be precipitated by an acid. According to Pelletier, by whom it was discovered, it possesses acid properties, forming with the alkalies and earths neutral compounds, which are of a blue colour, and soluble in alcohol and ether. He calls it *anchusic acid*, and states that it may be sublimed unchanged. (*Journ. de Pharm.*, xix. 105.) The tincture of alkanet has its colour deepened by the acids, changed to blue by the alkalies, and again restored by neutralizing the latter substances. It may, therefore, be used as a test. The extract obtained by evaporating the tincture is dark-brown.

Alkanet root is somewhat astringent, and was formerly applied to the treatment of several diseases; but it is now employed exclusively for colouring oils, ointments, and plasters, which are beautifully reddened by one-fortieth of their weight of the root. It is said also to be used in the preparation of spurious port wine.

ALLIARIA OFFICINALIS. *Erysimum Alliaria.* Linn. *Hedge Garlic.* A perennial European herb, having an alliaceous odour when rubbed, and a bitterish, somewhat acrid taste. When eaten it communicates its smell to the breath. Mr. Wertheim obtained from the

root a volatile oil, apparently identical with that of mustard. (*Ann. der Chem. und Pharm.*, liii. 52.) The herb and seeds are esteemed diuretic, diaphoretic, and expectorant, and have been given in humoral asthma, chronic catarrh, and other complaints in which garlic is useful. The herb has also been recommended as an external application in gangrenous affections, and to promote suppuration.

ALNUS GLUTINOSA. *Common European Alder.* A European tree, twenty-five feet or more in height, growing in swamps, on the sides of streams, and in other damp places. The bark and leaves are very astringent, and somewhat bitter. The former has been used in intermittent fever, the latter as a topical remedy in wounds and ulcers. The bruised leaves are sometimes applied to the breast for the purpose of repelling the milk. The cones also are said to be astringent, and to form a useful gargle in complaints of the throat. All these parts of the tree are used in dyeing, and the leaves and bark in tanning. The *Alnus serrulata*, or common *American alder*, has analogous properties.

AMBERGRIS. *Ambra grisea.* This substance, which is found floating on the sea, or thrown by the waves upon the shores of various countries, particularly in the southern hemisphere, is now generally believed to be produced in the intestines of the *Physeter macrocephalus* or spermaceti whale, and perhaps in those of some other fish. It is in roundish or amorphous pieces, usually small, but sometimes of considerable magnitude; and masses have been found weighing 50, 100, and even 200 pounds. These pieces are often composed of concentric layers. They are of various colours, usually gray, with brownish, yellow, and white streaks, often dark-brown or blackish on the external surface. They are opaque, lighter than water, and of a consistence like that of wax. Ambergris has a peculiar aromatic agreeable odour, is almost tasteless, softens with the warmth of the hand, melts under 212°, is almost completely volatilizable by heat, and is inflammable. It is insoluble in water, but is readily dissolved, with the aid of heat, by alcohol, ether, and the volatile and fixed oils. It consists chiefly of a peculiar fatty matter analogous to cholesterin, and denominated by Pelletier and Caventou *ambrein*. This may be obtained by treating ambergris with heated alcohol, filtering the solution, and allowing it to stand. Crystals of ambrein are deposited. It differs from most other fatty matters in not forming soaps with the alkalies. When pure it has little or no odour. Ambergris is often adulterated; but does not then exhibit its ordinary fusibility and volatility. It was long regarded as a cordial and antispasmodic, somewhat analogous to musk; and has been recommended in typhoid fevers, and various nervous diseases. It formerly entered into many officinal preparations, and is still retained in some of the European Pharmacopœias. It is, however, feeble as a remedy, and is much more used in perfumery than in medicine. The dose is from five grains to a drachm.

AMMONIO-TARTRATE OF IRON. *Ferri Ammonio-tartras.* This salt was first employed by Mr. Aiken, of London. According to Professor Procter, of this city, it is best prepared by dissolving to saturation, freshly precipitated hydrated sesquioxide of iron in a solution of bitartrate of ammonia. The bitartrate may be made by saturating fifty drachms of tartaric acid, dissolved in a gallon of water, with carbonate of ammonia, and then adding fifty drachms of the acid to the solution formed. This is heated, by means of a water-bath, with the fresh hydrated sesquioxide, derived from fifty-three and a third drachms of U. S. subcarbonate of iron, dissolved in muriatic acid and precipitated by ammonia. The sesquioxide is dissolved, and a deep reddish-brown solution results, which is evaporated to dryness by means of a water-bath. This double salt, when prepared in small quantities, is in brilliant scales, dark-brown in mass, but garnet-red by transmitted light. When obtained in considerable quantities, it forms angular grains, resembling kino. It is very soluble in water, and has a strongly saccharine taste. Its aqueous solution undergoes no change by a boiling temperature. According to an analysis by Prof. Procter, it consists of two eqs. of tartaric acid, one of sesquioxide of iron, one of ammonia, and four of water. (*Am. Journ. of Pharm.*, xii. 275.) This salt has the general properties of the other ferruginous compounds. Its advantages are its ready solubility, palatable taste, and permanency. The dose is five grains or more, given in pill or solution.

ANACARDIUM OCCIDENTALE. Linn. *Cassuvium pomiferum.* Lam. *Cashew-nut.* A small and elegant tree, growing in the West Indies, and other parts of tropical America. A gum exudes from the bark, which bears some resemblance to gum Arabic, but is only in part soluble in water, and consists of true gum and bassorin. It is the *gomme d'acajou* of the French writers. The fruit is a fleshy, pear-shaped receptacle, supporting at its summit, a hard, shining, ash-coloured, kidney-shaped nut, an inch or more in length, and three-quarters of an inch broad, consisting of two shells, with a black juice between them, and of a sweet oily kernel. The receptacle is red or yellow, and of an agreeable subacid flavour with some astringency. It is edible, and affords a juice which has been recommended in uterine complaints and dropsy. This juice is converted by fermentation into

a vinous liquor, which yields a spirit by distillation, used in making punch, and said to be powerfully diuretic. The nuts are well known under the name of *cashew-nuts*. The black juice, contained between their outer and inner shell, is extremely acrid and corrosive, producing, when applied to the skin, severe inflammation, followed by blisters or desquamation. It has been examined chemically by Stoedeler, who found in it two peculiar principles, one having acid properties, which he calls *anacardic acid*, and the other a yellow, oleaginous liquid, named *cardol*. (See *Journ. de Pharm.*, 3*e sér.*, xiii. 459.) The juice is used in the West Indies for the cure of corns, warts, ringworms, and obstinate ulcers, and is said to be sometimes applied to the face by females in order to remove the cuticle, and produce a fresher and more youthful aspect. In a case of external poisoning which came under our notice, in a lady who was exposed to the fumes of the nut while roasting, the face was so much swollen that for some time not a feature was discernible. The kernel, when fresh, has a sweet, agreeable taste, and is eaten like chestnuts, either raw or roasted. It is also used as an ingredient of puddings, &c., and forms an excellent chocolate when ground with cocoa. By age it becomes rancid. The black juice of the nut and a milky juice which flows from the tree by incision, are sometimes used for marking linen, upon which they leave a nearly indelible brown or black stain.

ANAGALLIS ARVENSIS. *Scarlet Pimpernel.* An annual plant, growing in Europe and this country, with small, delicate, procumbent stems, furnished with opposite branches, opposite ovate leaves, and small scarlet flowers, which are supported upon axillary, solitary peduncles, and appear in June and July. It is inodorous, and has a bitterish, somewhat acrid taste. The ancients esteemed it a counter-poison, and in modern times it has been used as a preventive of hydrophobia; but at present no faith is placed in its alexipharmic powers. It is, nevertheless, not wholly inactive; as Orfila found three drachms of an extract prepared from it sufficient to destroy a dog, with marks of inflammation of the bowels. It has been recommended as a local application in old and ill-conditioned ulcers, and has been given internally in visceral obstructions, consumption, dropsy, epilepsy, mania, &c. But too little is known of its precise properties, to authorize its indiscriminate employment in these complaints. Another species, considered by Linnæus as a mere variety of the A. arvensis, is *A. cærulea*, distinguished by its blue flowers. The medical properties of the two, so far as is known, are the same.

ANCHUSA OFFICINALIS. *Bugloss.* This species of Anchusa is a native of Europe, and unknown in the United States. It is a biennial plant, from one to three feet high, and was formerly much esteemed as a medicine. The root, leaves, and flowers were officinal. These are inodorous and nearly tasteless. The root is mucilaginous and slightly sweetish, and the flowers very feebly bitter. The plant has no claim whatever to the credit, formerly attached to it, of possessing cordial and exhilarating properties. It was used by the ancients in hypochondriacal affections, but, as it was given in wine, the elevation of spirits was probably due to the vehicle. In France, the *Anchusa Italica*, which is there known as *buglosse*, is employed for the same purposes and in the same manner as Borago officinalis.

ANDROMEDA ARBOREA. *Sorrel-tree.* A beautiful indigenous tree, growing in the valleys of the Alleghany mountains, from Pennsylvania to Florida. The leaves have a very pleasant acid taste, which has given rise to the common name of the tree. They are used by hunters to allay thirst, and form in decoction a grateful refrigerant drink in fevers. The other species of Andromeda are shrubs, and some of them ornamental. Dr. Barton, in his "Collections," states that a decoction of *A. Mariana* is employed in the Southern States, as a wash in a disagreeable ulceration of the feet to which the negroes are liable. The powder upon the leaves and buds of *A. speciosa* is said to be a powerful errhine.

ANEMONE PRATENSIS. *Meadow Anemone.* This plant enjoyed at one time considerable credit from the recommendation of Störck, who believed that he had found it useful in amaurosis and other complaints of the eye, in secondary syphilis, and in cutaneous eruptions. Dr. J. de Ramm found it also very useful in hooping-cough. *A. Pulsatilla* (*pulsatilla*), an analogous species, has been employed for similar purposes; and favourable reports have been made of its efficacy in obstinate diseases of the skin, and in hooping-cough. The preparation employed was an extract of the herbaceous part of the plant, which was given by Störck in the dose of one or two grains daily, gradually increased to twenty grains or more. In large doses it was found frequently to produce nausea and vomiting, or griping and looseness of the bowels, and sometimes acted as a diuretic. It is, we believe, a favourite remedy with the homœopathists. The species of Anemone above mentioned are European plants, and are not cultivated in this country. We have several native species. One of them, *A. nemorosa*, which is common to Europe and the United States, is said to act as a poison to cattle, producing bloody urine and convulsions. It is stated also to have proved, when applied to the head, a speedy cure for tinea capitis. Most of the species are, in the recent state, acrid and rubefacient, resembling in this respect

other Ranunculaceæ. They contain a peculiar crystallizable principle, named *anemonin*, convertible into *anemonic acid*, by the action of alkalies. (*Ann. der Pharm.*, xxxii. 276.) It is deposited by water distilled from the fresh herb upon standing, and resembles camphor. According to J. Müller, it is formed by a metamorphosis of the acrid matters which are distilled with the water. (*Pharm. Cent. Blatt*, Sept. 11, 1850, p. 618.)

ANIMÉ. *Gum Animé.* The substance known at present by the name of *anime* is a resin supposed to be derived from the *Hymenæa Courbaril*, a tree of South America; though this origin is denied by Hayne. According to Dr. W. Hamilton, the resin exudes from wounds in the bark, and is found also underneath the surface of the ground, between the principal roots. (*Pharm. Journ. and Trans.*, vi. 522.) It is in small, irregular pieces, of a pale lemon-yellow colour, sometimes inclining to reddish, more or less transparent, covered with a whitish powder, brittle and pulverizable, with a shining fracture, a weak but agreeable odour, and a mild resinous taste. It softens in the mouth, adheres to the fingers when in the state of powder, and readily melts with heat, diffusing its agreeable odour in an increased degree. It consists of two distinct resins, one soluble, the other insoluble in cold alcohol, and of a small proportion of volatile oil. There is a variety of a darker colour, less transparent, and exhibiting small cavities in the interior; in other respects resembling the preceding. Another variety of anime is the East Indian, supposed to be derived from *Vateria Indica;* but this never reaches us as a distinct article of commerce. Anime formerly entered into the composition of various ointments and plasters; but is now used only as incense, or in the preparation of varnishes. The Brazilians are said to employ it internally in diseases of the lungs.

ANNOTTA. *Orleana.* The colouring substance called *annotta*, *arnotta*, or *roucou*, is the reddish pulp surrounding the seeds in the fruit of *Bixa Orellana*, a middling-sized tree growing in Guiana, and other parts of South America. The pulp is separated by bruising the fruit, mixing it with water, then straining through a sieve, and allowing the liquid to stand till the undissolved portion subsides. The water is then poured off, and the mass which remains, having been sufficiently dried, is formed into flat cakes or cylindrical rolls, and sent into the market. Annotta is of a brownish-red colour, usually rather soft, but hard and brittle when dry, of a dull fracture, of a sweetish peculiar odour, and a rough, saline, bitterish taste. It is inflammable, but does not melt with heat. It softens in water, to which it imparts a yellow colour, but does not dissolve. Alcohol, ether, the oils, and alkaline solutions dissolve the greater part of it. It contains a peculiar crystallizable colouring principle, to which M. Preisser, its discoverer, gave the name of *bixin*. (See *Journ. de Pharm.*, 3e *sér.*, v. 258.) The chief uses to which annotta is applied are for dyeing silk and cotton orange-yellow, and for colouring cheese. The colour, however, which it imparts to cloth is fugitive. It has been given internally as a medicine; but is not now used, and probably exercises little influence upon the system. In pharmacy it is used to colour plasters, and has occasionally been substituted for saffron. It is said to be sometimes largely adulterated; and red ochre, powdered bricks, and colcothar have been employed for the purpose. If these substances be present, they will be left behind when the annotta is burned.

ANTHRAKOKALI. This preparation, introduced by Dr. Polya, is of two kinds, the simple and the sulphuretted. The *simple anthrakokali* is formed by adding 160 parts of porphyrized mineral coal to 192 parts of a concentrated and boiling solution of caustic potassa, contained in an iron vessel, the whole being well stirred together. When the mixture is completed, the vessel is taken from the fire, and the stirring continued until the whole is converted into a homogeneous black powder. The *sulphuretted anthrakokali* is prepared in a similar manner, 16 parts of sulphur being mixed with the mineral coal before it is added to the caustic potassa solution. Dr. Polya recommends these preparations both internally and externally, in scrofula, chronic rheumatism, rheumatic tumours of the joints, and certain herpetic affections. The dose is a grain and a half three or four times a day, mixed with two or three times its weight of powdered liquorice root. For external use, sixteen grains may be rubbed with an ounce of lard, to form an ointment, to be used by friction night and morning. (*Journ. de Pharm.*, xxvi. 545, and 3e *sér.*, ii. 153.)

ANTHRISCUS CEREFOLIUM. De Cand. *Chærophyllum sativum.* Lam. *Scandix Cerefolium.* Linn. *Chervil.* An annual European plant, cultivated in gardens as a potherb, and supposed by some physicians to possess medicinal powers. It has a strong agreeable odour, especially when rubbed, and a pungent, slightly bitterish taste. These properties it owes to a volatile oil, which may be separated by distillation with water. It is said to be deobstruent, diuretic, and emmenagogue, and has been recommended by different authors in consumption, scrofula, dropsy, cutaneous and scorbutic affections, and as an external application to swollen breasts, bruises, and other local complaints or injuries. It is, however, very feeble, and is more used as an addition to broths than as a medicine.

ANTIRRHINUM LINARIA. Linn. LINARIA VULGARIS. Lindley. *Common Toad-flax.* This is a perennial herbaceous plant, from one to two feet high, with numerous narrow linear leaves, and a terminal crowded spike of large yellow flowers. It is a native of Europe, but has been introduced into this country, and now grows in great abundance along the road sides, through the Middle States. It is readily distinguishable by the shape of its leaf, and its conspicuous yellow flowers, which appear in succession from June to October. The herb is the part used. It should be collected when in flower, dried quickly, and kept excluded from the air. When fresh it has a peculiar, heavy, rather disagreeable odour, which is in a great measure dissipated by drying. The taste is herbaceous, weakly saline, bitter, and slightly acrid. This plant is said to be diuretic and cathartic, and has been used in dropsy, jaundice, and cutaneous eruptions. It is most conveniently employed in infusion. The fresh plant is sometimes applied, in the shape of poultice or fomentation, to hemorrhoidal tumours; and an ointment made from the flowers has been employed for the same purpose, and also locally in diseases of the skin. The flowers are used in Germany for dyeing yellow.

AQUA BINELLI. An Italian nostrum, named after a physician of Turin, which at one time enjoyed great reputation in Europe as a styptic; but has been proved to possess very little efficacy. It is a transparent liquid, with little taste and an empyreumatic odour, and, after the discovery of creasote, was conjectured to contain a small proportion of that principle. It is now out of use. A recipe for its preparation is given in the *Annuaire de Thérapeutique*, 1843, p. 227.

AQUILEGIA VULGARIS. *Columbine.* A perennial herbaceous plant, indigenous in Europe, but cultivated in our gardens as an ornamental flower. All parts of it have been medicinally employed. The roots, leaves, and flowers have a disagreeable odour, and a bitterish, acrid taste. The seeds are small, black, shining, inodorous, and of an oleaginous sweetish taste, followed by a sense of acrimony. Columbine has been considered diuretic, diaphoretic, and antiscorbutic, and has been employed in jaundice, in small-pox to promote the eruption, in scurvy, and externally as a vulnerary. It is not used at present, and is even suspected to possess dangerous properties, like most other Ranunculaceæ.

ARECA NUT. *Betel Nut.* This is the product of Areca Catechu, an East India tree belonging to the family of palms. The fruit, which is about the size and shape of a small egg, and of an orange-yellow colour, contains the nut embedded in a fibrous, fleshy envelope, and invested with a brittle shell which adheres to the exterior flesh. The kernel, which is the betel-nut of commerce, is of a roundish conical shape, rather larger than a chestnut, externally of a deep-brown, diversified with a fawn colour, so as to present a reticular appearance, internally brownish-red with whitish veins, very hard, of a feeble odour when broken, and of an astringent, somewhat acrid taste. It abounds in tannin, and contains also gallic acid, a fixed oil, gum, a little volatile oil, lignin, and various saline substances. It yields its astringency to water; and, in some parts of Hindostan, an extract is prepared from it having the appearance and properties of catechu. Immense quantities of the nut are consumed in the East, mixed with the leaves of the Piper Betel, and with lime, forming the masticatory so well known by the name of *Betel*. The red colour which this mixture imparts to the saliva and the excrements is owing to the Areca nut, which is also powerfully astringent, and, by its internal use, tends to counteract the relaxation of bowels to which the heat of the climate so strongly predisposes. The nut is used in this country almost exclusively in the preparation of tooth-powder, for which purpose it is first reduced by heat to the state of charcoal. The superiority of this form of charcoal over that from other sources is probably owing to its hardness.

ARGEMONE MEXICANA. *Prickly Poppy.* An annual plant, belonging to the Papaveraceæ, growing in our Southern and Western States, Mexico, the West Indies, Brazil, and in many parts also of Africa and Southern Asia. It has an erect, somewhat glaucous, bristly stem, with alternate sessile leaves, sinuated and prickly at the angles, and usually marked with white spots. The flowers are solitary, yellow or white, with two or three prickly deciduous sepals, four or six large petals, about twenty stamens, and four to six reflexed stigmas. The whole plant abounds in a milky, viscid juice, which becomes yellow on exposure to the air. From the statements of different authors, it may be inferred that the plant is emetic and purgative, and possesses also narcotic properties. The juice, which is acrid, has been used internally in obstinate cutaneous eruptions, and as a local application to warts and chancres, and in diseases of the eye. The flowers are stated by De Candolle to have been employed as a soporific. But the seeds are most esteemed. They are small, round, black, and roughish. In the dose of two drachms, infused in a pint of water, they are said to act as an emetic. In smaller doses they are purgative. An oil may be obtained from them by expression, which has the cathartic properties of the seeds.

ARSENIATE OF AMMONIA. *Ammoniæ Arsenias.* This salt is obtained in crystals by saturating a concentrated solution of arsenic acid with ammonia or carbonate of ammonia, and allowing it to evaporate spontaneously. It has been used with advantage by Biett in several inveterate diseases of the skin. It is administered in solution, formed by dissolving a grain of the salt in a fluidounce of distilled water. Of this the dose is from twenty to twenty-five drops, given in the course of the day, and gradually increased.

ARSENIATE OF IRON. *Ferri Arsenias.* This salt may be formed by double decomposition, by adding a solution of sulphate of iron to one of arseniate of soda. It precipitates in the form of a dirty-green powder. It has been used by Carmichael, diluted with four times its weight of phosphate of iron, as a caustic application to cancerous ulcers. It may be made into an ointment by being mixed with twelve times its weight of spermaceti cerate. Internally it has been given in cancerous affections, in the form of pill, in the dose of the sixteenth of a grain three times a day.

ASARABACCA. This is the product of the *Asarum Europæum*, an herbaceous perennial plant, growing in Europe, between 37° and 60° north latitude, in woods and shady places, and flowering in May. All parts of the plant are acrid. The leaves were specially directed by the London College, when the plant was recognised as officinal; but the whole plant, including root, stem, leaves, and flowers, is usually kept in the shops. The root is about as thick as a goose-quill, of a grayish colour, quadrangular, knotted and twisted, and sometimes furnished with radicles at each joint. It has a smell analogous to that of pepper, an acrid taste, and affords a grayish powder. The leaves, which have long footstalks, are kidney-shaped, entire, somewhat hairy, of a shining deep-green colour when fresh, nearly inodorous, with a taste slightly aromatic, bitter, acrid, and nauseous. Their powder is yellowish-green. Both parts rapidly lose their activity by keeping, and ultimately become inert. Geiger, however, asserts that they keep well if perfectly dry. Their virtues are imparted to alcohol and water, but are dissipated by decoction. According to MM. Feneulle and Lassaigne, the root contains a concrete volatile oil, a very acrid fixed oil, a yellow substance analogous to *cytisin*, starch, albumen, mucilage, citric acid, and saline matters. The latest analysis is by Gräger, who found in the *root* a liquid volatile oil, two concrete volatile substances called respectively *asarum camphor* or *asarone*, and *asarite*, a peculiar bitter principle called *asarin*, tannin, extractive, resin, starch, gluten, albumen, lignin, citric acid, and various salts; in the *leaves*, asarin, tannin, extractive, chlorophylle, albumen, citric acid, and lignin. The active principles appear to be the volatile oil, which is lighter than water, glutinous, yellow, of an acrid and burning taste, and a smell like that of valerian, and the asarin, which is soluble in alcohol and very bitter, and is probably the same as the cytisin of Feneulle and Lassaigne. The root and leaves of asarabacca, either fresh or carefully dried, are powerfully emetic and cathartic, and were formerly much used in Europe with a view to these effects. The dose is from thirty grains to a drachm. But as an emetic they have been entirely superseded by ipecacuanha; and they are now used chiefly, if not exclusively, as an errhine. The powdered root, snuffed up the nostrils in the quantity of one or two grains, produces much irritation, and a copious flow of mucus, which is said to continue sometimes for several days. The leaves are milder, and generally preferred. They should be used in the quantity of three or four grains repeated every night until the desired effect is experienced. They have been strongly recommended in headache, chronic ophthalmia, and rheumatic and paralytic affections of the face, mouth and throat.

ASCLEPIAS CURASSAVICA. *Bastard Ipecacuanha. Redhead. Blood Weed.* This is a very pretty species of Asclepias, from one to three feet high, and bearing umbels of bright-red flowers. It is a native of the West Indies, abounding especially in the Island of Nevis and St. Kitts, where it is considerably used as a medicine. Both the root and the expressed juice are emetic, the former in the dose of one or two scruples, the latter in that of a fluidounce or more. They are also cathartic in somewhat smaller doses; and the expressed juice, made into a syrup with sugar, has been strongly recommended as a remedy in worms. The medicine, however, is somewhat uncertain in its operation. According to Dr. W. Hamilton, the plant may also be usefully employed in arresting hemorrhages, and in the treatment of obstinate gonorrhœa, in which it has been found very efficient by Dr. Barham. (See *Am. Journ. of Pharm.*, xix. 19.)

ASPARAGUS OFFICINALIS. *Asparagus.* This well known garden vegetable is a native of Europe. It is perennial and herbaceous. The *root*, which is inodorous, and of a weak sweetish taste, was formerly used as a diuretic, aperient, and purifier of the blood; and it is stated to be still employed to a considerable extent in France. It is given in the form of decoction, made in the proportion of one or two ounces of the root to a quart of water. Hayne asserts that, in the dried state, it is wholly inert. The *young shoots* are much used as food. Before being boiled they have a disagreeable taste; and their juice was found by Robiquet and Vauquelin to contain a peculiar crystallizable principle, called

asparagin (see *page* 77), which, however, is not known to exert any special influence on the system. The sprouts themselves are not without effect, as the urine acquires a disagreeable odour very soon after they have been eaten. They are considered by some writers as diuretic, aperient, and deobstruent, and as constituting a very wholesome and useful article of diet, early in the spring, when vegetables are scarce. Broussais thought that they were sedative to the heart, and recommended them especially in hypertrophy, and other diseases of that organ attended with excessive action, and without phlogosis of the stomach. M. Gendrin, however, after much experience with asparagus, affirms that he never knew it to exercise the slightest influence over the heart, and ascribes its palliative effects, in diseases of that organ, to a diuretic action. He found it, in all the cases in which he administered it, to increase the quantity of urine, which, in some instances, was quintupled. The most convenient forms for exhibition are those of syrup and extract, prepared from the shoots The former may be given in the dose of one or two fluidounces, the latter, of half a drachm or a drachm. The syrup may be made by adding a sufficient quantity of sugar to the expressed juice of the shoots, previously deprived of its albumen by exposure to heat and by filtration; the extract, by evaporating the same juice to the consistence of a pilular mass. The *berries* are capable of undergoing the vinous fermentation, and affording alcohol by distillation. In their unripe state they possess the same properties as the shoots, and probably in a much higher degree. We have employed a syrup prepared from them, with apparent advantage, in a case of diseased heart.

ASPLENIUM FILIX FŒMINA. R. Brown. *Female Fern.* This is the *Polypodium Filix fœmina* of Linn., the *Aspidium Filix fœmina* of Swartz, and the *Athyrium Filix fœmina* of Roth. It has a root analogous in character to that of the male fern (*Aspidium Filix mas*), and has been supposed to possess similar vermifuge properties. At present, however, it is not used. The vulgar name of *female fern* is also given to the *Pteris aquilina*, or *common brake*, which is said by some authors to have the property of destroying the tape-worm. The leaves of two species of Asplenium, *A. Trichomanes*, or *common spleenwort*, and *A. Adiantum-nigrum*, or *black spleenwort*, are mucilaginous, and have been used as substitutes for the *maidenhairs* (*Adiantum Capillus Veneris* and *A. pedatum*) as pectorals, though destitute of the aromatic flavour which is the chief recommendation of these plants.

BALM OF GILEAD. *Balsam of Gilead. Balsamum Gileadense. Baume de la Mecque*, Fr. The genuine balm of Gilead is the resinous juice of the *Amyris Gileadensis* of Linn., the *Balsamodendron Gileadense* of Kunth, a small evergreen tree, growing on the Asiatic and African shores of the Red Sea. It was in high repute with the ancients, and still retains its value in the estimation of the eastern nations, among whom it is employed both as a medicine and cosmetic. In western Europe and in this country, it is seldom found in a state of purity, and its use has been entirely abandoned. It is described as a turbid, whitish, thick, gray, odorous liquid, which becomes solid by exposure. It possesses no medical properties which do not exist in other balsamic or terebinthinate juices. It was formerly known by the name of *opobalsamum;* while the dried twigs of the tree were called *xylobalsamum*, and the dried fruit, *carpobalsamum.*

BALSAM OF SULPHUR. This name was formerly given to a substance resulting from the reaction of sulphur upon olive oil at a high temperature. It was directed in the old Edinburgh Pharmacopœia, under the name of *Oleum Sulphuratum;* but was discharged from that work at the last revision. The directions of the College were to boil *eight parts* of olive oil and *one part* of sublimed sulphur together, with a gentle fire, in a large iron pot, stirring them constantly till they united. The iron pot should be large enough to hold three times the quantity of the materials employed, as the mixture might otherwise boil over. As the vapours which rise are apt to take fire, a lid should be at hand to cover the pot, and thus extinguish the flame if necessary. Sulphur is soluble to a considerable extent in heated oil, from which, if the solution be saturated, it is deposited in a crystalline state on cooling. But it is not a mere solution which this process is intended to effect. The oil is partly decomposed, and the resulting preparation is an extremely fetid, acrid, viscid, reddish-brown fluid. In order that it may be obtained, the oil must be heated to the boiling point. *Sulphurated oil*, or *balsam of sulphur*, was formerly thought useful in chronic catarrh, consumption, and other pectoral complaints; but inconvenience has arisen from its acrid properties, and its internal use has been abandoned. It is said to be sometimes applied as a stimulant to foul ulcers. The dose is from five to thirty drops.

BALSAMUM TRANQUILANS. *Baume Tranquille.* This is a preparation of some note, directed by the French Codex, and consisting essentially of olive oil holding in solution the active matters of certain narcotic and aromatic plants. The fresh plants are boiled with the oil until all their water is driven off; the oil is then expressed and poured upon the dried plants properly comminuted; and the mixture, having been allowed to stand for a month, is strained, and the oil decanted. The preparation is used by friction as an anodyne in local pains.

BAPTISIA TINCTORIA. *Sophora tinctoria.* Linn. *Podalyria tinctoria.* Michaux. *Wild Indigo.* This is an indigenous perennial plant, found in all parts of the United States, growing abundantly in woods and dry barren uplands. It is from one to three feet high, with a smooth, very branching stem, small, ternate, cuneate-obovate, bluish-green leaves, and yellow flowers, which appear in July and August, and, like the whole plant, become black when dried. The root, which is the part most highly recommended, is of a dark-brown colour, inodorous, and of a nauseous, somewhat acrid taste. Its virtues appear to reside chiefly in the cortical portion. In large doses, it is said to operate violently as an emetic and cathartic; in smaller, to produce only a mild laxative effect. It is said to have proved useful in scarlatina, typhus fever, and in that state of system which attends gangrene or mortification. Dr. Thacher speaks highly of its efficacy as an external application to obstinate and painful ulcers; and Dr. Comstock, of Rhode Island, found it extremely useful, both as an internal and external remedy, in threatened or existing mortification. By the latter physician it was given in decoction, made in the proportion of an ounce of the root to a pint of water, of which half a fluidounce was administered every four or eight hours, any tendency to operate on the bowels being checked with laudanum. Dr. Stevens, of Ceres, Pennsylvania, has employed a decoction of the root advantageously in epidemic dysentery. (*N. Y. Journ. of Med.*, iv. 358.) It may be used externally in the form of decoction or cataplasm. The stem and leaves possess the same virtues as the root, though in a less degree. A pale-blue colouring substance has been prepared from the plant as a substitute for indigo, but is greatly inferior.

BARBADOES NUTS. *Purging Nuts. Physic Nuts.* These are the seeds of the *Curcas purgans* of Adanson (*Jatropha Curcas* of Linnæus), growing in Brazil, the West Indies, and on the western coast of Africa. The fruit is a three-celled capsule, containing one seed in each cell, and is of about the size of a walnut. The seeds are blackish, oval, about eight lines long, flat on one side, convex on the other; and the two sides present a slight longitudinal prominence. They yielded to Soubeiran fixed oil, an acrid resin, sugar, gum, a fatty acid, gluten, a free acid, and salts. The oil may be separated by expression. When fresh it is without smell or colour, but becomes yellowish and slightly odorous by time. When cold it deposits a white substance, which is probably margarin. Alcohol does not readily dissolve it. Some call it *jatropha oil.* From three to five of the *seeds*, slightly roasted and deprived of their envelope, operate actively as a cathartic, and not unfrequently produce nausea and vomiting, with a sense of burning in the stomach. The *oil* purges in the dose of twelve or fifteen drops, and is analogous in its action to croton oil, though less powerful. The cake left after the expression of the oil is an acrid emeto-cathartic, operating in the dose of a few grains. Either of these substances may produce serious consequences in over-doses. The leaves of the plant are rubefacient, and the juice is said to have been usefully employed as a local remedy in piles.

The seeds of *Curcas multifidus* (*Jatropha multifida*, Linn.) have similar properties, and yield a similar oil. This species also grows in Brazil and the West Indies.

BASSORA GUM. The plant which yields this substance is unknown. It came into commerce originally from the neighbourhood of Bassora, on the Gulf of Persia, but is frequently found mixed with gum brought from other countries, and is probably not the product of one plant exclusively. It is in irregular pieces, of various sizes, never very large, white or yellow, intermediate in the degree of its transparency between gum Arabic and tragacanth, inodorous, tasteless, and possessed of the property of yielding a slight sound when broken under the teeth. But a small portion of it is soluble in water, whether hot or cold. The remainder swells up considerably, though less than tragacanth, and does not, like that substance, form a gelatinous mass, as it consists of independent granules which have little cohesion. The soluble portion is pure gum or *arabin*, and, according to M. Guérin, constitutes 11·2 per cent. The insoluble portion consists of a peculiar principle called *bassorin*, associated with a small proportion of saline substances, which yield, when the gum is burnt, 5·6 per cent. of ashes. The gum is useless both in medicine and pharmacy, and is described here only as containing a principle which enters into the composition of several medicinal substances.

Bassorin is insoluble in water, alcohol, and ether, but softens and swells up in hot or cold water. Diluted nitric and muriatic acids, with the aid of heat, dissolve it almost entirely. The acidulous solution, concentrated by evaporation, and treated with alcohol, lets fall a flocculent precipitate which has all the characters of pure gum, into which the bassorin appears to have been converted by the action of the acid. This does not, however, constitute more than a tenth part of the bassorin dissolved. By gradually evaporating the alcoholic acidulous solution, a thick bitterish liquid is obtained, which exhales a strong odour of ammonia when treated with potassa. Strong nitric acid converts bassorin into mucic and oxalic acids; and, treated with sulphuric acid, it yields a sweet crystalline

substance which is incapable of the vinous fermentation. (Guérin.) Vauquelin was the first to call attention to this principle, upon which he conferred its present name, from having first observed it in the Bassora gum. Bucholz afterwards discovered the same or a closely analogous principle in tragacanth; and John, a principle which was supposed to be the same, in the gum of the cherry tree; hence it has sometimes been called *tragacanthin* and *cerasin*. M. Guérin, however, has demonstrated that the insoluble principle of the cherry gum is essentially different from bassorin. Berzelius considers the latter as belonging to the class of substances which he associates under the name of mucilage, and of which the mucilages of flaxseed and quince seed are examples. (See *Linum*, p. 448.)

BDELLIUM. This name has been given to two different gum-resins, distinguished as *Indian* and *African bdellium*. Dr. Royle was informed that the former was obtained from the *Amyris Commiphora* of Roxburgh, growing in India and Madagascar. The latter is said to be the product of *Heudelotia Africana*, which grows in Senegal. Bdellium sometimes comes mixed with gum Arabic and gum Senegal. It is either in small roundish pieces, of a reddish colour, semi-transparent, and brittle, with a wax-like fracture, or in larger irregular lumps, of a dark brownish-red colour, less transparent, somewhat tenacious, and adhering to the teeth when chewed. It has an odour and taste like those of myrrh, but weaker. It is infusible and inflammable, diffusing while it burns a balsamic odour. According to Pelletier it consists of 59 per cent. of resin, 9·2 of gum, 30·6 of bassorin, and 1·2 of volatile oil, including loss. In medical properties it is analogous to myrrh, and was formerly used for the same purposes; but it is now scarcely ever given internally. In Europe, it is still occasionally employed as an ingredient of plasters. The dose is from ten to forty grains.

BEAN OF ST. IGNATIUS. *Faba Sancti Ignatii.* This is the product of the *Ignatia amara* of the younger Linnæus, which is now considered a species of Strychnos, and entitled *S. Ignatia.* (See *Nux Vomica.*) It is a tree of middling size, with numerous long, cylindrical, glabrous, vine-like branches, which bear opposite, nearly sessile, oval, pointed, entire, and very smooth leaves. The flowers are white, tubular, fragrant, and arranged in short axillary racemes. The fruit is of the size and shape of a pear, with a smooth, whitish, ligneous rind, enclosing about twenty seeds embedded in a dry pulpy matter, and lying one upon the other. These seeds are the part used. The tree is a native of the Philippine Islands, where the seeds were highly esteemed as a medicine, and, having attracted the attention of the Jesuits, were honoured with the name of the founder of their order. They are about an inch long, rather less in breadth, still less in thickness, convex on one side, obscurely angular, with two, three, or four faces on the other, and marked at one end with a small depression indicating their point of attachment. They are externally of a pale-brown colour, apparently smooth, but covered in fact with a short down or efflorescence, which may be removed by scraping them with a knife. They are somewhat translucent, and their substance is very hard and horny. They have no smell, but an excessively bitter taste. To Pelletier and Caventou they afforded the same constituents as nux vomica, and among them 1·2 per cent. of strychnia.

MM. Magendie and Delile have proved that they act on the human system in the same manner as nux vomica. In the Philippines they have been employed for the cure of obstinate intermittents, and in numerous other diseases. It is probable that in small doses they act as a tonic. In this country they are never used. We have noticed them here on account of their comparatively large proportion of strychnia, which is triple that contained in nux vomica. They are employed for the extraction of that principle.

BEBEERU BARK. The bark of a tree growing in British Guiana, which has recently been brought into notice as a powerful tonic and febrifuge. The tree is a species of *Nectandra*, and has been named by Sir Robert Schomburg, *N. Rodiei*, in honour of Dr. Rodie, by whom it was first described. The bark is in flat pieces, three or four lines thick, smooth, grayish, hard, heavy, and brittle. The fruit is as large as a small apple, obcordate or obovate, somewhat compressed, consisting of an exterior brittle shell, and an interior fleshy kernel. Both the bark and the fruit are intensely bitter. They contain two alkaline principles discovered by Dr. Rodie, and named respectively *bebeerin* and *sipeerin*. These are extracted together, in the form of sulphates, by a process similar to that for preparing sulphate of quinia. The preparation is of a dark colour, and has the appearance of an extract. Messrs. Maclagan and Tilley obtain pure *bebeerin* by the following process. The impure sulphate is dissolved in water, and precipitated by ammonia. The precipitate, mixed with an equal weight of recently precipitated oxide of lead, and dried, is treated with absolute alcohol, which, being evaporated, leaves the two alkalies in the form of a translucent resinoid mass. The bebeerin is separated by means of ether, which yields it by evaporation. It is pale-yellow, of a resinous appearance, uncrystallizable, very soluble in alcohol, less so in ether, and very slightly soluble in water. It softens

and melts with heat, and at a higher temperature takes fire. Its salts are uncrystallizable. (*Journ. de Pharm.*, 3e *sér.*, x. 89.) The sulphate, above referred to, has been employed, with great asserted success, in the treatment of intermittent and remittent fevers. Dr. Rodie recommended it so early as 1834; but it did not attract general attention until brought into notice by Dr. Douglas Maclagan, of Edinburgh, who published a number of observations tending to prove its possession of valuable antiperiodic properties. Others afterwards confirmed his statements in its favour, and it was hoped that a substitute had been found for the alkaloids of Peruvian bark; but the more recent published accounts by M. Becquerel, of France (*Journ. de Pharm.*, 3e *sér.*, xx. 439), of Dr. Wm. Pepper, of Philadelphia (*Am. Journ. of Med. Sci.*, N. S., xxv. 13), and of Dr. E. D. Dailey, of Smyrna, Delaware (*Med. Exam.*, N. S., ix. 557), show satisfactorily that, though frequently successful, it often fails, and cannot be relied on as a substitute for quinia. From a scruple to a drachm may be given between the paroxysms, in doses of two grains.

BEDEGUAR. *Fungus Rosarum.* An excrescence upon the *sweet briar* or *eglantine*, and other species of *Rosa*, produced by the puncture of insects, especially by one or more species of *Cynips*. It is of irregular shape, usually roundish, about an inch in diameter, with numerous cells internally, in each of which is the larva of an insect. It has little smell, and a slightly astringent taste. Though formerly considered diuretic, anthelmintic, and lithontriptic, and employed as a remedy for toothache, it has fallen into disuse. It was given in doses of from ten to forty grains.

BENZOATE OF AMMONIA. *Ammoniæ Benzoas.* This salt is formed by dissolving benzoic acid nearly to saturation in a warm solution of ammonia. Upon cooling the solution forms crystals, which are somewhat deliquescent, and very soluble in water. Benzoate of ammonia is deemed diuretic, and has been employed in dropsy. Dr. Seymour, of London, used it with beneficial effects in gout, and also in cases in which chalk stones were deposited near the joints.

BENZOIN ODORIFERUM. Nees. *Laurus Benzoin.* Linn. *Spice-wood. Spice-bush. Fever-bush.* An indigenous shrub, from four to ten feet high, growing in moist, shady places, in all parts of the United States. Its flowers appear early in spring, long before the leaves, and are succeeded by small clusters of oval berries, which, when ripe, in the latter part of September, are of a shining crimson colour. All parts of the shrub have a spicy, agreeable flavour, which is strongest in the bark and berries. The small branches are sometimes used as a gently stimulant aromatic, in the form of infusion or decoction. They are said to be employed in this way by the country people as a vermifuge, and an agreeable drink in low fevers; and the bark has been used in intermittents. The berries, dried and powdered, were sometimes substituted, during the revolutionary war, for allspice. According to Dr. Drake, the oil of the berries is used as a stimulant.

BENZOLE. *Benzine. Benzene. Phene. Hydruret of Phenyle.* This substance was originally obtained by distilling benzoic acid with lime. It was afterwards discovered by Faraday as a constituent of coal-gas tar. This tar, when distilled, furnishes coal-naphtha, a complex substance, containing a number of carbohydrogens, among which is benzole. Upon distilling this naphtha from a metallic still, surmounted with an open vessel filled with water, and containing a worm terminating in a refrigerated receiver, the benzole will pass over and condense in the receiver; while the other substances associated with it, having higher boiling points, will condense in the worm, and fall back into the still. The benzole is then purified by distillation at a heat between 176° and 194°, and by subjecting the product to a new distillation from one-fourth of its volume of sulphuric acid.

Benzole is a colourless oleaginous liquid, possessing an agreeable odour. Its sp. gr. is 0·85, congealing point 32°, and boiling point 176°. Its formula is $C_{12}H_6$. Its powers as a solvent are very extensive. Among the substances soluble in it are sulphur, phosphorus, and iodine. It dissolves quinia, but not cinchonia, with which it forms a bulky, gelatinous mass. Morphia and strychnia are sparingly soluble. It is also a solvent of many of the resins; as also of mastic, camphor, wax, fatty and essential oils, caoutchouc, and gutta percha. The last two substances may be obtained, without alteration of properties, in tough sheets of any desired tenuity, by spreading their benzole solutions on glass or other polished surface, and allowing the solvent to evaporate. The same solutions brushed over the skin, form artificial cuticles, which have been found useful as coverings to wounds and burns. The vapour of benzole, when inhaled, acts as an anæsthetic. In relation to this substance see the paper of C. B. Mansfield, in the *Chem. Gaz.* (No. 159, p. 224), from which the facts of this article are principally taken.

Benzole, by the action of concentrated fuming nitric acid, is converted into *nitrobenzole*, also called *nitrobenzule* and *nitrobenzide*, having the formula $C_{12}H_5,NO_4$. The product, after having been washed with water, forms an oily, yellowish, intensely sweet liquid, having an odour like that of oil of bitter almonds. Its density is 1·209, and boiling point

415°. Latterly, it has become of commercial importance under the name of *artificial oil of bitter almonds*, being employed in scenting soaps, in confectionery, and for flavouring articles of diet. Nitrobenzole may be viewed as benzole, in which one eq. of hydrogen is replaced by one of nitrous acid.

BERBERIS VULGARIS. *Barberry.* A shrub growing wild in Europe and the United States, and sometimes cultivated in gardens on account of its berries. These grow in loose bunches, are oblong, and of a red colour, have a grateful, sour, astringent taste, and contain malic and citric acids. They are refrigerant, astringent, and antiscorbutic, and are used in Europe, in the form of drink, in febrile diseases and diarrhœas. An agreeable syrup is prepared from the juice; and the berries are sometimes preserved for the table. The root and inner bark have been used for dyeing yellow, and are said to have been employed beneficially in jaundice. They owe their colouring property to a peculiar crystallizable principle, which has been named *berberin*, and which is said, in the dose of from one to ten grains, to be tonic and purgative. (*Journ. de Pharm.*, xxi. 309.) This principle has been ascertained to possess alkaline properties. (See *Chem. Gaz.*, April, 1847, p. 129, and June, 1847, p. 209.) It is a vulgar error to suppose that the vicinity of this plant is injurious to wheat. The American plant differs slightly from the European, and is described by Pursh as a distinct species, under the name of *B. Canadensis*. It grows in mountains and hilly districts from Canada to Virginia. The berries are smaller and much less juicy than those of the garden barberry.

BETONICA OFFICINALIS. *Wood Betony.* A perennial European herb, belonging to the labiate plants. It has a pleasant but feeble odour, and a warm, somewhat astringent, and bitterish taste. By the ancients it was much esteemed, and employed in numerous diseases; but it is at present little used. It is slightly warming and corroborant, but is inferior in this respect to many other plants of the same family. The root has been considered emetic and purgative.

BETULA ALBA. *Common European Birch.* Various parts of this tree have been applied to medical uses. The *inner bark*, which is bitterish and astringent, has been employed in intermittent fever. The epidermis is separable into thin layers, which may be employed as a substitute for paper, and are applied to various economical uses. The bark contains a peculiar principle, called *betulin*, which is ranked among the sub-resins. When the bark is distilled, it yields an empyreumatic oil, having the peculiar odour of Russia leather, in the preparation of which it is employed. The *leaves*, which have a peculiar, aromatic, agreeable odour, and a bitter taste, have been employed, in the form of infusion, in gout, rheumatism, dropsy, and cutaneous diseases. The same complaints, particularly dropsy, are said to have been successfully treated by enveloping the body in the fresh leaves, which thus applied excite perspiration. When the stem of the tree is wounded, a saccharine *juice* flows out, which is considered useful in complaints of the kidneys and bladder, and is susceptible, with yeast, of the vinous fermentation. A beer, wine, spirit, and vinegar are prepared from it, and used in some parts of Europe.

Of the American species of birch, *Betula lenta*, variously called *sweet birch*, *black birch*, *cherry birch*, and *mountain mahogany*, is remarkable for the aromatic flavour of its bark and leaves, which have the odour and taste of Gaultheria procumbens, and are sometimes used in infusion, as an agreeable, gently stimulant, and diaphoretic drink. An oil is obtained by distillation from the bark, which has been proved by Prof. Procter to be identical with oil of gaultheria. (*Am. Journ. of Pharm.*, xv. 243.) This species also affords a saccharine liquor, which, indeed, appears to be common to all the birches. The bark of *B. papyracea* is employed by the Northern Indians for making canoes; and thin layers of the epidermis are placed inside of boots to prevent the access of moisture.

BEZOAR. This name has been applied to concretions which form in the stomach or intestines of animals, and which were at one time thought to possess extraordinary medical virtues. Numerous varieties have been noticed; but they were all arranged in two classes, the *oriental bezoar* (*lapis bezoar orientalis*), and *western bezoar* (*lapis bezoar occidentalis*), of which the former was most esteemed. They have fallen into merited neglect.

BIRD-LIME. A viscid substance existing in various plants, particularly in the bark of *Viscum album*, and *Ilex aquifolium* or European holly, from the latter of which it is usually procured. The process for preparing it consists in boiling the middle bark for some hours in water, then separating it from the liquid, and placing it in proper vessels in a cool situation, where it is allowed to remain till it becomes viscous. It is then washed to separate impurities, and constitutes the substance in question. Bird-lime thus prepared is greenish, tenacious, glutinous, bitterish, and of an odour analogous to that of flaxseed oil. Exposed to the air in thin layers it becomes dry, brown, and pulverizable, but re-acquires its viscidity upon the addition of water. It is a complex body, but is thought to owe its characteristic

properties to a proximate principle, identical with that which exudes spontaneously from certain plants, and is called *glu* by the French chemists. This principle is without odour or taste, extremely adhesive, fusible by heat, inflammable, insoluble in water, nearly insoluble in alcohol, but dissolved freely by ether and oil of turpentine. According to M. Macaire, it is insoluble in the fixed oils, either hot or cold. This property distinguishes it from the resins, to which Berzelius is disposed to attach it. M. Macaire proposes for it the name of *viscin*. (*Journ. de Pharm.*, xx. 18.) Bird-lime is so tenacious, that it may be employed to catch small birds, which, when they alight on a stick thickly covered with it are unable to escape.

BISTORT. This is the root of *Polygonum Bistorta*, a perennial herbaceous plant, growing in Europe and the North of Asia. The root is cylindrical, somewhat flattened, about as thick as the little finger, marked with annular or transverse wrinkles, furnished with numerous fibres, and folded or bent upon itself, so as to give it the tortuous appearance from which its name was derived. When dried it is solid, brittle, of a deep-brown colour externally, reddish within, destitute of smell, and possessed of a rough, astringent taste. It contains much tannin, some gallic acid and gum, and a large proportion of starch. It resembles the other vegetable astringents in medical properties, and is applicable to the same complaints; but is less efficient than catechu or kino, and in this country is seldom or never used. It may be employed in the form of powder, decoction, or extract. The dose of the powder is twenty or thirty grains, three or four times a day.

Besides the bistort, some other plants belonging to the genus Polygonum have been used as medicines. Among these are *P. aviculare*, or knot-grass, a mild astringent, formerly employed as a vulnerary and styptic; *P. Persicaria* (Persicaria mitis), of a feebly astringent saline taste, and at one time considered antiseptic: and *P. Hydropiper* or water-pepper (Persicaria urens), the leaves of which have a burning and biting taste, inflame the skin when rubbed upon it, and are esteemed diuretic. The *water-pepper* or *smart-weed* of this country—*P. punctatum* (Elliott), *P. hydropiperoides* (Michaux)—which grows abundantly in moist places, possesses properties similar to those of the European water-pepper, and is occasionally used as a detergent in chronic ulcers, and internally in gravel. Dr. Eberle very strongly recommended it in amenorrhœa, in which complaint he found no other remedy equally effectual. He gave a fluidrachm of the saturated tincture of the plant, or from four to six grains of the extract, three or four times a day. He found it to produce a warmth and peculiar tingling sensation throughout the system, with slight aching pains in the hips and loins, and a sense of weight and tension within the pelvis. (*Eberle's Mat. Med. 4th ed.*, i. 441.) Dr. Wilcox, of Elmira, New York, has found advantage from a decoction of the dried leaves, made in the proportion of an ounce to the pint, and applied locally, in mercurial salivation, and the sore-mouth of nursing-women. (*Am. Journ. of Med. Sci.*, N. S., xvi. 248.) *P. Fagópyrum* is common *buckwheat*.

BISULPHURET OF CARBON. *Carburet of Sulphur.* This compound is formed by passing the vapour of sulphur over charcoal, heated to redness in a porcelain tube. Prepared on the large scale, the charcoal may be heated in a cast iron cylinder, as recommended by M. Chandelon. (*Journ. de Pharm. 3e sér.*, xiv. 187.) It is a transparent, colourless, exceedingly volatile liquid, having a pungent, somewhat aromatic taste, and a very fetid smell. Its sp. gr. is 1·272. In composition it is a bisulphuret. It acts as a diffusible stimulant, accelerating the pulse, augmenting the animal heat, and exciting the secretions of the skin, kidneys, and genital organs. It was formerly employed in obstinate rheumatic and arthritic affections, in paralysis and cutaneous eruptions, and more recently as a resolvent in indolent tumours. It is used both internally and externally. For internal exhibition in gout and rheumatism, Dr. Otto, of Copenhagen, employed an alcoholic solution, in the proportion of two drachms to the fluidounce, of which four drops were given every two hours. At the same time the affected parts were rubbed with a liniment, made by dissolving the bisulphuret in the same proportion in olive oil. Dr. Krimer applied it to an indolent tumour, by allowing forty or fifty drops to fall upon it three times a day. This treatment, which may be supposed to act by the cold produced, assisted by the internal use of animal charcoal and cicuta, and the employment of warm alkaline baths, was attended with success. He also succeeded in reducing several strangulated hernias, by applying some drops of the bisulphuret to the hernial tumour. By Dr. Turnbull the vapour of this substance was found useful, applied to indurated lymphatic glands, and for the removal of deafness, when dependent on want of nervous energy, and a deficiency of wax. It is applied by means of a bottle with a proper sized mouth, containing a fluidrachm of the bisulphuret, imbibed by a piece of sponge. The skin over the gland is first well moistened with water. When the vapour is applied to the ear, the bottle, having a small neck to fit the meatus, is held close to the organ until considerable warmth is produced. (*Pharm. Journ. and Trans.*, ii. 352.)

BOLE ARMENIAN. The term *bolus* or *bole* was formerly applied to various forms of argillaceous earth, differing in colour, or place of origin. Such were the *Armenian*, *Lemnian*, and *French boles*, and the *red* and *white boles*. Some of these substances were so highly valued as to be formed into small masses and impressed with a seal, and hence received the name of *terræ sigillatæ*. They were all similar in effect, though the small proportion of oxide of iron contained in the coloured boles may have given them greater activity. The only one at present kept in the shops is that called *bole Armenian*, from its resemblance to the substance originally brought from Armenia. It is prepared, by trituration and elutriation, from certain native earths existing in different parts of Europe. It is in pieces of various sizes, reddish, soft and unctuous, adhesive to the tongue, and capable of forming a paste with water. It consists chiefly of alumina and silica, coloured with oxide of iron. The boles were formerly employed as absorbents and astringents; and they were undoubtedly useful in some cases of acidity of the stomach and relaxed bowels. The bole Armenian is used chiefly as a colouring ingredient in tooth powders.

BORAGO OFFICINALIS. *Borage.* This is an annual, hairy, succulent European plant, one or two feet high, with fine blue flowers, on account of which it is sometimes cultivated in our gardens. All parts of it abound in mucilage, and the stem and leaves contain nitrate of potassa with other salts. To these constituents the plant owes all its virtues. It is much used in France. An infusion of the leaves and flowers, sweetened with honey or syrup, is employed as a demulcent, refrigerant, and gently diaphoretic drink in catarrhal affections, rheumatism, diseases of the skin, &c. The expressed juice of the stem and leaves is also given in the dose of from two to four ounces. The flowers are sometimes applied externally as an emollient. A distilled water, extract, and syrup were formerly used, but have fallen into neglect. Borage is scarcely known in this country as a medicinal plant.

BRAZIL WOOD. A red dye-wood, the product of different species of Cæsalpina, growing in the West Indies and South America. Two varieties are known in commerce:— 1. The proper Brazil-wood, said to be derived from *Cæsalpina echinata*, and sometimes called *Pernambuco* or *Fernambuco wood*, from the province of Brazil, where it is collected; 2. the *brasiletto*, produced by *C. Brasiliensis* and *C. Crista*, which grow in Jamaica and other parts of the West Indies. The former is the most highly valued. The *sappan* or *sampfen wood* may be referred to the same head, being obtained from the *Cæsalpina Sappan*, and possessing properties analogous to those of the brasiletto. The *Nicaragua* or *peach wood* is also analogous to the brasiletto, and is said by Bancroft to be derived from a species of Cæsalpina. It is produced in the East Indies. Brazil wood is nearly inodorous, has a slightly sweetish taste, stains the saliva red, and imparts its colouring matter to water. It was formerly used in medicine; but has been abandoned as inert. In pharmacy it serves to colour tinctures, &c.; but its chief use is in dyeing. A red lake is prepared from it, and it is an ingredient in a red ink. Its dyeing properties are owing to a crystallizable colouring principle, named *breselin*.

BROMIDE OF IRON. *Ferri Bromidum.* This bromide is obtained by heating gently, in thirty parts of water, two parts of bromine, and one of iron filings. When the liquid becomes greenish, it is filtered and evaporated to dryness in an iron vessel; and the dry mass, again dissolved and evaporated to dryness, furnishes the bromide. Bromide of iron is a brick-red deliquescent salt, very soluble, and extremely styptic. For medicinal employment it should be in aqueous solution, protected by sugar. Mr. Dillwyn Parrish has proposed the following formula: Take of bromine *two hundred grains;* iron filings *eighty-five grains;* distilled water *four and a half fluidounces;* sugar *three ounces*. Make a solution in the manner directed for preparing solution of iodide of iron. (*Med. Exam.* vii. 162.) This solution is deemed tonic and alterative. It has been used with advantage by Dr. E. Gillespie, of Brady's Bend, Pa., in tetter, scrofulous tumours, inflammation of the glands, both acute and chronic, erysipelas, and amenorrhœa. In the case of tumours and erysipelas, Dr. Gillespie, besides giving the solution internally, applies it to the parts affected by means of a feather two or three times a day. (*Ibid.*, vii. 158.) The dose of Mr. Parrish's solution is twenty drops, three times a day, gradually increased until some effect is produced on the system. Bromide of iron is formed as the first step of the process for preparing the officinal bromide of potassium. (See *page* 1149.)

BROMIDES OF MERCURY. The *protobromide* is formed by adding bromide of potassium to nitrate of protoxide of mercury. It falls as a white curdy precipitate. The *bibromide* may be obtained by digesting the protobromide in water containing bromine. It is in the form of colourless crystals, soluble in water and alcohol. Exposed to heat it enters into fusion and sublimes. These bromides are analogous in composition and medicinal properties to the corresponding iodides of mercury. (See *pages* 1036 and 1037.) The protobromide is given in the dose of a grain daily, gradually increased. The bi-

bromide, like corrosive sublimate, is an irritant poison, and may be administered in doses of the sixteenth of a grain, gradually increased to a fourth, either in the form of pill, or in ethereal solution, made by dissolving a grain in a fluidrachm of ether.

BRYONY. *White Bryony.* This is the root of *Bryonia alba*, or white bryony, a perennial, climbing, herbaceous plant, growing in thickets and hedges in different parts of Europe. It bears rough, heart-shaped, five-lobed leaves, small yellow monœcious flowers, arranged in racemes, and roundish black berries about the size of a pea. Another species called *B. dioica*, with dioecious flowers and red berries, bears so close a resemblance in character and properties to the preceding, that it is considered by some botanists merely a variety. The roots of both plants are gathered for use. When fresh they are spindle-shaped, sometimes branched, a foot or two in length, as thick as the arm, or even thicker, externally yellowish-gray and circularly wrinkled, within white, succulent and fleshy, of a nauseous odour, which is lost in great measure by drying, and of a bitter, acrid, very disagreeable taste. The peasants are said sometimes to hollow out the top of the root, and to employ the juice which collects in the cavity as a drastic purge. (*Merat and De Lens.*) The berries are also purgative, and are used in dyeing.

As kept in the shops, the root is in circular transverse slices, externally yellowish-gray and longitudinally wrinkled, internally of a whitish colour, becoming darker by age, concentrically striated, light, brittle, and readily pulverizable, yielding a whitish powder. Besides a peculiar bitter principle called *bryonin*, the root contains starch in considerable proportion, gum, resin, sugar, a concrete oil, albumen, and various salts. It yields its active properties to water.

Bryony is an active hydragogue cathartic, in large doses sometimes proving emetic, and disposed, if too largely administered, to occasion inflammation of the alimentary mucous membrane. The recent root is highly irritant, and is said, when bruised and applied to the skin, to be capable of producing vesication. The medicine was well known to the ancients, and has been employed by modern physicians; but is now nearly superseded by jalap, which is more certain, and less liable to lose its strength by age. The dose of the powdered root is from a scruple to a drachm.

CABBAGE-TREE BARK. The bark of *Andira inermis*, De Cand., *Geoffroya inermis*, Willd., figured in Woodville's Medical Botany, p. 416, t. 151. This is a leguminous tree, with a stem rising to a considerable height, branched towards the top, and covered with a smooth gray bark. The leaves are pinnate, consisting of six or seven pairs of ovate lanceolate, pointed, veined, smooth, petiolate leaflets, with an odd one at the end. The flowers are rose-coloured, and arranged in terminal panicles, with very short pedicels. The tree is a native of Jamaica and other West India Islands. The bark, which is the part used, is in long pieces, thick, fibrous, externally of a brownish-ash colour, scaly and covered with lichens, internally yellowish, of a resinous fracture, a disagreeable smell, a sweetish, mucilaginous, bitterish taste, and affording a powder resembling that of jalap. Huttenschmidt obtained from it a crystallizable, very bitter substance, having the composition and neutralizing properties of the vegetable alkaloids, and named very inappropriately *jamaicina*. Two grains of it produced violent purging in pigeons.

On the continent of Europe the bark of *Andira retusa* (*Geoffroya Surinamensis*), which grows in Surinam, has also been employed. It is considered more powerfully vermifuge, without being equally liable to produce injurious effects. It has a grayish epidermis, beneath which it is reddish-brown, laminated, compact, very tenacious, and, when cut transversely, exhibits a shining and variegated surface. In the dried state it is inodorous, but has an austere bitter taste. The powder is of a pale-cinnamon colour.

Cabbage-tree bark is cathartic, and in large doses is apt to occasion vomiting, fever, and delirium. It is said that these effects are more liable to result if cold water is drunk during its operation, and are relieved by the use of warm water, castor oil, or a vegetable acid. In the West Indies it is esteemed a powerful vermifuge, and is much employed for expelling lumbrici; but it is dangerous if incautiously administered, and instances of death from its use have occurred. It is almost unknown in this country, and does not enter into our officinal catalogues. The usual form of administration is that of decoction, though the medicine is also given in powder, syrup, and extract. The dose of the powder is from a scruple to half a drachm, of the extract three grains, of the decoction two fluidounces.

CAHINCA. This medicine attracted at one time considerable attention. The name of *cahinca* or *cainca* was adopted from the language of the Brazilian Indians. The Portuguese of Brazil call the medicine *raiz pretta* or black root. When first noticed in Europe it was supposed to be derived from the *Chiococca racemosa* of Linnæus, which was known to botanists as an inhabitant of the West Indies. But Martius, in his "Specimen Materiæ Medicæ Brasiliensis," describes two other species of Chiococca, *C. anguifuga* and *C. densifolia*, which afford roots having the properties of that ascribed to *C. racemosa;* and, as

the medicine was brought from Brazil, there seemed to be good reason for referring it to one or both of the plants named by that botanist. A. Richard, however, received from Brazil specimens of *C. racemosa* as the cahinca plant.

A specimen brought into this market consisted of cylindrical pieces, varying in size from the thickness of a straw to that of the little finger, somewhat bent or contorted, slightly wrinkled longitudinally, with occasional small asperities, internally ligneous, externally covered with a thin brittle reddish-brown bark, having a light-brown or brownish ash-coloured epidermis. The cortical portion, which was of a resinous character, had a bitter disagreeable taste, somewhat acrid and astringent: the ligneous part was quite tasteless. The virtues of the root reside almost exclusively in its bark. They are extracted by water and alcohol. Cahinca has been analyzed by several chemists. Four distinct principles were discovered in it by Pelletier and Caventou:—1. a crystallizable bitter substance, believed to be the active principle, and called *cahincic acid;* 2. a green fatty matter of a nauseous odour; 3. a yellow colouring matter; and 4. a coloured viscid substance. Rochleder and Hlasiwetz found also caffeotannic acid. By these chemists a tincture obtained by boiling the bark in alcohol, was precipitated first with a spirituous solution of acetate of lead, and afterwards, having been previously filtered, with the tribasic acetate of lead. The first precipitate consisted chiefly of caffeotannate and a portion of cahincate of lead, the second of cahincate of lead exclusively. To obtain the caffeotannic acid separate, the first precipitate was treated with sulphuretted hydrogen, and afterwards with neutral acetate of lead, and in like manner several times, until at length a pure caffeotannate of lead remained, which, on decomposition, yielded an acid identical with the tannic acid of coffee. The cahincic acid was obtained by treating the second precipitate with sulphuretted hydrogen, and concentrating the resulting liquid. The chemists last mentioned give as its formula $C_{16}H_{13}O_7$. (*Chem. Gaz.*, ix. 121.) Cahincic acid is white, without smell, of a taste at first scarcely perceptible, but afterwards extremely bitter and slightly astringent, of difficult solubility in water, but readily soluble in alcohol, permanent in the air, and unaltered at 212°. It reddens vegetable blues, and unites with the alkalies, but does not form crystallizable salts. It is thought to exist in the root as subcahincate of lime.

Medical Properties. Cahinca is tonic, diuretic, purgative, and emetic. In moderate doses it gently excites the circulation, increases the discharge of urine, and produces evacuations from the bowels; but is rather slow in its operation. It may be made to act also as a diaphoretic, by keeping the skin warm, using warm drinks, and counteracting its purgative tendency. In some patients it occasions nausea and griping, and in very large doses always acts powerfully both as an emetic and cathartic. In Brazil it has long been used by the natives as a remedy for the bites of serpents; and its Indian name is said to have been derived from this property. According to Martius, the bark of the fresh root is rubbed with water till the latter becomes charged with all its active matters; and the liquid, while yet turbid, is taken in such quantities as to produce the most violent vomiting and purging, preceded by severe spasmodic pains. Patrick Brown speaks of the root of *C. racemosa* as very useful in obstinate rheumatisms. But the virtues of cahinca in dropsy, though well known in Brazil, were first made known to the European public in the year 1826, by M. Langsdorff, Russian Consul at Rio Janeiro. Achille Richard afterwards published a few observations in relation to it in the *Journal de Chimie Medicale;* and its properties were subsequently investigated by numerous practitioners. M. François, of Paris, contributed more than any other physician to its reputation. It was considered by him superior to all other remedies in dropsy. But general experience has not confirmed the partial estimate of Dr. François; and, having been found at least equally uncertain with other diuretics, the medicine is now little used. It was employed in substance, decoction, extract, and tincture. The powdered bark of the root was given as a diuretic and purgative, in a dose varying from a scruple to a drachm; but the aqueous or spirituous extract was preferred. The dose of either of these is from ten to twenty grains. Dr. François recommended that, in the treatment of dropsy, a sufficient quantity should be given at once to produce a decided impression, which should afterwards be maintained by smaller doses, repeated three or four times a day.

CALENDULA OFFICINALIS. *Marygold.* This well-known garden plant was formerly much employed in medicine. It has a peculiar, rather disagreeable odour, which is lost by drying, and a bitter, rough, saline taste. Among its constituents is a peculiar principle, called *calendulin*, discovered by Geiger most abundantly in the flowers, and considered by Berzelius as analogous to bassorin, though soluble in alcohol. The plant was thought antispasmodic, sudorific, deobstruent, and emmenagogue, and was given in low forms of fever, scrofula, jaundice, amenorrhœa, &c. Both the leaves and flowers were used; but the latter were preferred, and were usually administered in the recent state, in the form of tea. An extract was also prepared, and employed in cancerous and other ulcers, sick stomach, &c. At present marygold is very seldom if ever used in regular practice.

CALOTROPIS GIGANTEA. Brown. *Asclepias gigantea*, Linn. Under the name of *madar* or *mudar*, a medicine has been employed in the East Indies, with great asserted advantage. It is the bark of the root of a species of Calotropis, generally considered as *C. gigantea*, but asserted by Dr. Casanova to be a distinct species, and named by him *C. Madurii Indico-orientalis*. *C. gigantea* is a native of Hindostan, and has been introduced into the West Indies, where it is now naturalized. The bark, as employed, is destitute of epidermis, of a whitish colour, nearly or quite inodorous, and of a bitter somewhat nauseous taste. It appears to have the general properties of many other acrid medicines; in small doses, increasing the secretions, and in larger, producing nausea and vomiting. According to Dr. Casanova, who published an essay upon the subject at Calcutta, it is especially directed to the skin, the capillaries and absorbents of which it stimulates to increased action. It is chiefly recommended as a remedy in the obstinate cutaneous diseases of tropical climates, such as elephantiasis and leprosy. It has been employed also in syphilis, dropsy, rheumatism, and hectic fever. It is given in substance in the dose of from three to twelve grains, three times a day, and gradually increased till it affects the system.

CAM WOOD. A red dye-wood, procured from the *Baphia nitida* of De Candolle, a leguminous tree, growing on the Western Coast of Africa. The wood is usually kept in the shops in the ground state. It yields its colouring matter scarcely at all to cold water, slightly to boiling water, and readily to alcohol and alkaline solutions. This colouring matter is thought to be identical with santalin.

CANARY SEED. The seeds of *Phalaris Canariensis*, an annual plant belonging to the grasses, originally from the Canary Islands, but now growing wild in Europe and the United States, and cultivated in many places. The seeds are ovate, somewhat compressed, about two lines long, shining, and of a light yellowish-gray colour externally, and brownish within. Their chief constituent is starch. They were formerly esteemed medicinal, but are now used only for emollient cataplasms. They are nutritive, and their meal is said to be mixed, in some places, with wheat flour, and made into bread. They are used as food for Canary birds.

CAOUTCHOUC. *Gum elastic. Indian Rubber.* This substance is the concrete juice of the *Siphonia Cahuchu* of Schreber and Willdenow, identical with the *Siphonia elastica* of Persoon, the *Jatropha elastica* of the younger Linnæus, and the *Hevea Guianensis* of Aublet. This is a large tree growing in Brazil, Guiana, and possibly also in Central America. (*Journ. of Phil. Col. of Pharm.*, iii. 292.) On being wounded, it emits a milky juice, which concretes on exposure, and constitutes the substance in question. A similar product is afforded by several other lactescent plants; but hitherto it is only the juice of the Siphonia that has been extensively collected. Caoutchouc comes to us in large flat pieces, or moulded into various shapes. These are formed by applying successive layers of the juice upon moulds of clay, which are broken and removed when the coating has attained a sufficient thickness and consistence. In the drying of these layers they are exposed to smoke, which gives to the concrete mass a blackish colour. The juice, when it concretes by exposure to the air, assumes on the outer surface a yellowish-brown colour, while the mass remains white or yellowish-white within. The recent juice contains, according to Faraday, 1·9 per cent. of vegetable albumen, traces of wax, 7·13 per cent. of a bitter azotized substance soluble in water and alcohol, 2·9 of a substance soluble in water but insoluble in alcohol, 56·37 of water with a little free acid, and only 31·7 of the pure elastic principle to which chemists have given the name of caoutchouc. Besides these principles the concrete juice, as it reaches us, generally contains soot derived from the smoke used in drying it. *Pure caoutchouc* is nearly colourless, and in thin layers transparent. It is highly elastic, lighter than water, without taste and smell, fusible at about 248°, remaining unctuous and adhesive upon cooling, inflammable at a higher temperature, insoluble in water, alcohol, the weak acids, and alkaline solutions, soluble in ether when entirely freed from alcohol, soluble also in most of the fixed and volatile oils, though at the expense of its elasticity. It is said, however, that the oils of lavender and sassafras dissolve it without change, and that, when precipitated by alcohol from its solution in cajeput oil, it is still elastic. But its best solvents, for practical purposes, are coal-naphtha, an empyreumatic oil obtained by distilling caoutchouc itself, and pure oil of turpentine. Caoutchouc is not affected by atmospheric air, chlorine, muriatic or sulphurous acid gas, or ammonia. It consists, according to Faraday, of 87·2 parts of carbon, and 12·8 of hydrogen.

By the action of sulphur caoutchouc acquires properties which greatly increase its value in the arts. It becomes of a black colour and horny consistence, preserves its elasticity under the influence both of heat and cold, is compressible with great difficulty, and resists the ordinary solvents, such as petroleum and oil of turpentine. In this state it is said to be *vulcanized*. The discovery of the process of *vulcanization* is ascribed to Mr. Charles Goodyear, of New York. (*Chem. Gaz.*, x. 193.) It consists in submitting caoutchouc in

thin sheets to the action of a mixture composed of 40 parts of sulphuret of carbon and 1 of chloride of sulphur. For fuller details the reader is referred to the *Journ. de Pharm.* (3e *sér.*, xvii. 205). But the same object may be effected in other methods. When thin layers of caoutchouc are immersed for two or three hours in melted sulphur at the heat of 240° F., they are penetrated by the sulphur, but undergo no change of properties. If now heated in an inert medium to a temperature of from 275° to 320°, a chemical reaction takes place, and the vulcanized product is obtained. The same result takes place if the caoutchouc be first pounded with from 12 to 20 per cent. of finely powdered sulphur, and then heated to the temperature requisite for vulcanization. In either case a portion of uncombined sulphur remains mechanically mixed with the vulcanized caoutchouc, from which it may be separated by various solvents, such as solutions of caustic soda or potassa, sulphuret of carbon, oil of turpentine, anhydrous ether, &c. The *desulphurated* product thus obtained, while exempt from the disadvantages arising from the reaction of free sulphur, is more porous than before. (*Ibid.*, xxi. 366.)

Caoutchouc is used for erasing pencil marks; in the formation of flexible tubes for the laboratory, and of catheters, bougies, pessaries, and other instruments for surgical purposes; in the melted state, as a luting to the joints of chemical apparatus; in the shape of thin layers, for covering the mouths of bottles, and for other purposes in which the exclusion of air and moisture is requisite; in the manufacture of water-proof cloth; and for numerous other purposes, to which its elasticity, and the resistance which it offers to the ordinary solvents, and to other powerful chemical agents, peculiarly adapt it. It may be brought to the state of thin layers, by softening the small flasks of it in ether containing alcohol, or boiling them in water, for fifteen minutes, and then distending them by means of air forced into them; and the same end may be attained by spreading its naphtha or ethereal solution upon a smooth surface, and allowing the solvent to evaporate. Tubes of caoutchouc may be made from its solution, or from the juice imported in the liquid state. A court-plaster prepared with caoutchouc has been considerably used, and from its impermeability by moisture is sometimes valuable. (See *Amer. Journ. of Pharm.*, xv. 38.) A convenient sticking plaster may be prepared by spreading the liquid caoutchouc, by a stiff brush, upon calico, soft leather, or thin sheets of vulcanized Indian rubber as found in the shops. Small thin pieces of caoutchouc may be very advantageously employed to suppress hemorrhage from leech-bites, &c., by first softening one surface of the piece by a taper, and when cool applying it firmly over the bleeding point. The cavity of a decayed tooth may be lined with caoutchouc, so as to prevent the access of air, and thus relieve pain, by fastening a piece firmly around the end of a rod, liquefying the surface by heat, then introducing it with pressure into the cavity, and again withdrawing it. Caoutchouc has been given internally in phthisis, in the dose of one or two grains, gradually increased. (*Ann. de Thérap.*, 1847, p. 73.)

CAPPARIS SPINOSA. *Caper-bush.* A low, trailing shrub, growing in the South of Europe and North of Africa. The buds or unexpanded flowers, treated with salt and vinegar, form a highly esteemed pickle, which has an acid, burning taste, and is considered useful in scurvy. The dried bark of the root was formerly officinal. It is in pieces partially or wholly quilled, about one-third of an inch in mean diameter, transversely wrinkled, grayish externally, whitish within, inodorous, and of a bitterish, somewhat acrid, and aromatic taste. It is considered diuretic, and was formerly employed in obstructions of the liver and spleen, amenorrhœa, and chronic rheumatism.

CARANNA. *Gum Caranna.* A resinous substance, in pieces of a blackish-gray colour externally, dark-brown internally, somewhat shining and translucent, brittle and pulverizable when dry, but, in the recent state, soft and adhesive like pitch, easily fusible, of an agreeable balsamic odour when heated, and of a bitterish resinous taste. (*Geiger.*) It is said to be derived from the *Amyris Caranna* of Humboldt, a tree growing in Mexico and South America. Geiger refers it also to the *Bursera gummifera* of the West India Islands; but the resin obtained from this tree is described by the French writers under the name of *resine de Gomart*, or *resine de chibou*, or *cachibou*, and is said to bear a close resemblance to the resin *tacamahac.*

CARBURET OF IRON. *Ferri Carburetum. Plumbago. Black Lead.* This substance has been used both internally and externally in cutaneous affections. For medical use it is reduced to very fine powder, and purified by being boiled in water, and digested with dilute nitromuriatic acid. The dose is from five to fifteen grains or more, three or four times a day, given in the form of powder or pill. The ointment is made by mixing from two to six drachms with an ounce of lard.

CARDAMINE PRATENSIS. *Cuckoo-flower.* This is a perennial herbaceous plant, with a simple, smooth, erect stem, about a foot in height. The leaves are pinnate; the radical, composed of roundish irregularly toothed leaflets, those of the stem alternate, with leaflets

which become narrower, more entire, and pointed as they ascend. The flowers are purplish-white or rose-coloured, and terminate the stem in a raceme approaching the character of a corymb. The plant is a native of Europe, and is found in the northern parts of our continent, about Hudson's Bay. It is a very handsome plant, abounding in moist meadows, which it adorns with its flowers in the months of April and May. The leaves are bitterish and slightly pungent, resembling in some measure those of water-cresses, and like them supposed to be possessed of antiscorbutic properties. In Europe they are sometimes added to salads. The flowers have the same taste with the leaves, and, when fresh, a somewhat pungent odour. When dried, they become inodorous and nearly insipid. They formerly possessed the reputation of being diuretic, and, since the publication of a paper by Sir George Baker, more than half a century ago, have been occasionally used as an antispasmodic in various nervous diseases, such as chorea and spasmodic asthma, in which they were successfully employed by that physician. They produce, however, little obvious effect upon the system, and are not employed in this country.

CATALPA CORDIFOLIA. *Bignonia Catalpa.* Linn. *Catalpa tree,* or *Catawba tree.* This is a beautiful indigenous flowering tree, occasionally cultivated for ornamental purposes. It is reputed to be poisonous. The seeds have been employed by several practitioners of continental Europe in asthma. M. Automarchi recommends a decoction made by boiling twelve ounces of water with three or four ounces of the seeds down to six ounces, the whole to be given morning and night.

CEANOTHUS AMERICANUS. *New Jersey Tea. Red-root.* A small indigenous shrub, growing throughout the United States. The root is astringent, and imparts a red colour to water. It is said to be useful in syphilitic complaints, in which it is given in the form of decoction, made with two drachms of the root to a pint of water. Schoepf states that it is purgative. The leaves were used during the revolutionary war as a substitute for tea. Dr. Hubbard recommends a strong infusion of the dried leaves and seeds, as a local application in aphthous affections of the mouth and fauces, and the sorethroat of scarlatina, and as an internal remedy in dysentery. (*Boston Med. and Surg. Journ.*, Sept. 30, 1835.)

CEDRON. The seeds of a tree growing in New Granada and Central America, and described by M. Planchon under the name of *Simaba Cedron*, in the *London Journal of Botany*, v. 566, from specimens sent by Mr. Wm. Purdie, curator of the Botanical Garden at Trinidad, to Sir Wm. J. Hooker. Mr. Purdie had received the first intimation of the value of this medicine from Dr. Cespedes, a physician of Bogota. The first account of it, however, which reached Europe appears to have been that of Dr. Luigi Rotellini, a physician of Saint Domingo, who had previously resided in New Granada. It was published in an Italian journal so early as the year 1846. In France it appears to have been made known through M. Jamord, who received information of its effects from M. Herran, Chargé d'Affaires in France of the Republic of Costa Rica. The fullest account that we have seen of the plant and its products is from the pen of Sir Wm. J. Hooker. (See *Pharm. Journ. and Trans.*, Jan. 1851, x. 344.)

Simaba Cedron belongs to the natural family of Simarubaceæ. It is a small tree, with an erect stem, not exceeding six inches in diameter, branching at top in an umbellate form, with large, glabrous, pinnate leaves, and pale-brown flowers in long, branching racemes. The fruit is a large, solitary drupe, containing a single seed. The whole plant appears to be impregnated with a bitter principle, but it is the seed only that is used. A specimen of the dried fruit and the separated seed was kindly sent to one of the authors from Cartago, in Costa Rica, by Dr. Guier, formerly of Philadelphia. It is light, of a yellowish-ash colour, flattish-ovate, with one edge convex and the other nearly straight, the convex outline terminating at each end in an obtuse point, of which that at the apex is most prominent. It is about two inches long, and sixteen lines in its greatest breadth. Within, the seed is loose and movable. The seed itself is about an inch and a half long, ten lines broad, and half an inch thick. It is convex on one side, flat or slightly concave on the other, and presents an oval scar near one extremity of the flat surface. It is hard and compact, but may be readily cut with a knife.

Cedron seed is inodorous, but of a pure and intensely bitter taste, not unlike that of quassia. It yields its virtues to water and alcohol. M. Lewry obtained from it a crystalline substance, of intense bitterness, freely soluble in boiling water and neutral to test paper, which he supposes to be the active principle, and proposes to name *cedrin*. He obtained it by first exhausting the cedron with ether, then submitting it to the action of alcohol, and crystallizing from the tincture. (*Journ. de Pharm. et de Chim.*, xix. 335.)

This medicine has long had great reputation in New Granada and Central America, as a remedy for the bite of serpents, being mentioned in the *History of the Buccaneers*, published in 1699, as useful for this purpose; and such continues to be the confidence of the natives in its virtues, that they have no fears of the poisonous bite of these reptiles, if

provided with the antidote. It is also highly esteemed in the prevention of hydrophobia, and in the treatment of intermittent fever, spasm of the stomach and bowels, and dyspeptic affections. Dr. Guier informed us that he had seen it once apparently successful in curing the bite of a poisonous serpent, and had used it effectually in cholera morbus, colic, and neuralgia of the face. Dr. J. B. Thompson, of London, has found it useful in gout. (*Med. Times and Gaz.*, April, 1852, p. 364.) To us it appears to be closely analogous to quassia, with which it is botanically allied. The dose used in Central America is one or two grains. M. Herran states that he had employed the remedy in eight cases of poisoning, and that his mode of using it was to administer five or six grains with a spoonful of brandy, and to dress the bite with the tincture. He had rarely occasion to repeat the dose to effect a cure. Dr. Rotellini says that it is poisonous in over-doses, and has occasioned death in the quantity of twenty-five or thirty grains. A vinegar has been prepared in London by macerating for seven days two scruples of the cedron in an ounce of distilled vinegar. The dose is from twenty minims to a fluidrachm. (*Pharm. Journ. and Trans.*, xii. 63.)

CELASTRUS SCANDENS. *Climbing Staff-tree.* A climbing indigenous shrub, growing from Canada to Carolina, and said to possess emetic, diaphoretic, and narcotic properties. The bark is the part employed. It has been used in chronic affections of the liver and secondary syphilis. For a full description of the plant, see Darlington's *Flora Cestrica*, p. 149. Other species of Celastrus, growing in various parts of the world, have been employed in medicine, though with little reputation.

CENTAUREA BENEDICTA. *Blessed Thistle. Carduus benedictus. Cnicus benedictus.* De Cand. This is an annual herbaceous plant, the stem of which is about two feet high, branching towards the top, and furnished with long, elliptical, rough leaves, irregularly toothed, barbed with sharp points at their edges, of a bright-green colour on their upper surface, and whitish on the under. The lower leaves are deeply sinuated, and stand on footstalks; the upper are sessile, and in some measure decurrent. The flowers are yellow, and surrounded by an involucre of ten leaves, of which the five exterior are largest. The calyx is oval, woolly, and composed of several imbricated scales, terminated by rigid, pinnate, spinous points. The plant is a native of the South of Europe, and is cultivated in gardens in other parts of the world. It has become naturalized in the United States. The period of flowering is June, when its medicinal virtues are in greatest perfection. The leaves are the officinal portion. They should be gathered when the plant is in flower, quickly dried, and kept in a dry place. The herb has a feeble unpleasant odour, and an intensely bitter taste, more disagreeable in the fresh than the dried plant. Water and alcohol extract its virtues. The infusion with cold water is a grateful bitter; the decoction is nauseous, and offensive to the stomach. The bitterness remains in the extract. The active constituents are volatile oil, and a peculiar principle for which the name of *cnicin* has been proposed. This is crystallizable, inodorous, very bitter, neither acid nor alkaline, scarcely soluble in cold water, more soluble in boiling water, and soluble in all proportions in alcohol. It consists of carbon, hydrogen, and oxygen, and is analogous to salicin in composition. In the dose of 4 or 5 grains it is said often to vomit, and in that of 8 grains to be useful in intermittent fevers. (*Ann. de Thérap.*, 1843, p. 206.) The blessed thistle may be so administered as to prove tonic, diaphoretic, or emetic. The cold infusion, made with half an ounce of the leaves to a pint of water, has been employed as a mild tonic in debilitated conditions of the stomach. A stronger infusion, taken warm while the patient is confined to bed, produces copious perspiration. A still stronger infusion, or decoction, taken in large draughts, provokes vomiting, and has been used to assist the operation of emetics. The herb, however, is at present little employed, as all its beneficial effects may be obtained from chamomile. The dose of the powder as a tonic is from a scruple to a drachm, that of the infusion two fluidounces.

CHELIDONIUM MAJUS. *Celandine.* A perennial herbaceous plant, growing wild in this country, about old houses and in rocky places; but supposed to have been introduced from Europe, where it is indigenous. It is one or two feet high, bears pinnate leaves and small peduncled umbels of yellow flowers, and, when wounded, emits a yellow, opaque juice. The whole plant is used. It has a faint unpleasant odour, and a bitter, acrid, durable taste, which is stronger in the roots than in the leaves. The odour is nearly lost by drying, but the taste remains. The yellow juice is bitter and exceedingly acrid, and when applied to the skin produces inflammation and even vesication. The plant, analyzed by MM. Chevalier and Lassaigne, afforded a bitter resinous substance of a deep-yellow colour; a kind of gum-resin of an orange-yellow colour, and bitter, nauseous taste; mucilage; albumen; and various saline substances, besides free malic acid and silica. Dr. Probst, of Heidelberg, has more recently found in it a peculiar acid denominated *chelidonic acid*; two alkaline principles, one of which forms neutral salts with the acids, and is called

chelerythrin in consequence of the intense redness of its salts, the other unites with but does not neutralize the acids, and is named *chelidonin;* and lastly a neuter, crystallizable, bitter principle, which from its yellow colour he calls *chelidoxanthin.* Chelerythrin appears to be an acrid narcotic poison. (*Annal. der Pharm.*, xxix. 113.) See *Sanguinaria*, page 646, for the mode of preparing it. Celandine is an acrid purgative, possessed also of diuretic, and perhaps diaphoretic and expectorant properties. In over-doses, it produces unpleasant effects, and is by some considered poisonous. By the ancients it was much esteemed as a remedy in jaundice; and it has been found useful in the same complaint by some modern physicians. It was the chief ingredient of the old *decoctum ad ictericos* of the Edinburgh Pharmacopœia. It has been given also, in other complaints, especially those of a scrofulous character, affecting the mesenteric and lymphatic glands, the skin, and the eyes. The yellow juice is often applied to corns and warts, which it destroys by stimulating them beyond their powers. The fresh herb is also applied locally about the pelvis, with asserted benefit, in amenorrhœa. The dose of the dried root or herb is from thirty grains to a drachm, that of the fresh root one or two drachms; and the same quantity may be given in infusion. The watery extract and expressed juice have also been employed. The dose of the former is from five to ten grains, of the latter from ten to twenty drops, to be gradually increased until the effects of the remedy are experienced.

CHELTENHAM SALT, ARTIFICIAL. Several artificial mixtures have been prepared, professing to be exact imitations of the saline ingredients in the chalybeate Cheltenham water; but the only ones which appear worthy of confidence are those prepared by Robert Alsop, Chemist, of London, and W. Hodgson, jun., druggist, of this city. The composition of the natural Cheltenham chalybeate is given at page 113. The imitation of Mr. Alsop, as analyzed by Dr. Faraday, contains the same solid and gaseous constituents as the natural water, except the sulphate of lime, which is very properly omitted; and in the same proportions precisely, with the exception that there is about twice as much free carbonic acid in the artificial preparation. The iron is present in the state of protoxide, and is immediately dissolved by the free carbonic acid, upon adding a sufficient quantity of water. The carbonic acid probably exists in a free state in the dry mixture; as there is no obvious agent present to cause it to be disengaged in the mere act of solution.

Mr. Alsop's artificial mixture is in the form of a powder, nearly white, possessing a saline and slightly ferruginous taste. It forms a good combination, in which the aperient property of the salts present is combined with the tonic virtue of the iron. It is considered to be useful in glandular obstructions, especially of the liver, and in scrofulous affections, attended with feeble digestion, sluggish bowels, and pallidness of skin. It is employed, also, with advantage in sick headache, habitual costiveness, and hemorrhoids. The dose is a teaspoonful, quickly dissolved by brisk stirring in half a pint of cold water, and swallowed immediately, before the iron has time to separate in an insoluble state. This quantity may be taken in the morning, fasting, and repeated once or twice after an interval of twenty minutes, or in the course of the day. To obtain its full tonic and alterative effects, it should be persevered with for a month or six weeks.

The artificial Cheltenham salt of Mr. Hodgson is identical with that of Mr. Alsop, and may be used with entire confidence for all the purposes to which the latter is applied.

CHLORIDE OF MAGNESIUM. *Magnesii Chloridum. Muriate of Magnesia.* When a concentrated solution of this salt is evaporated to dryness, it is partially decomposed into magnesia and muriatic acid, the latter being evolved. By a careful evaporation, stopping it so soon as the vapour begins to redden litmus paper, the chloride may be obtained in the state of a fused hydrate, having the composition $MgCl,6HO$. (Casaseca, *Chem. Gaz.*, Oct. 15, 1853, p. 384.) The physiological action of this bitter and very deliquescent salt has been made the subject of a memoir by Dr. Lebert. He finds it to act mildly and favourably as a purgative, producing a flow of bile, and an increase of appetite. On account of its extreme deliquescence, he recommends it in the liquid form, prepared by dissolving the salt in its weight of water. Of this solution he gives an ounce sufficiently diluted to an adult, and half an ounce to a child from 10 to 14 years of age. (*Arch. Gén*, *4e sér.*, iii. 448.)

CHLORIDE OF MERCURY AND QUINIA. *Hydrargyri et Quiniæ Chloridum.* This compound has been prepared by Mr. McDermott, of Dublin, by uniting chemically corrosive sublimate with quinia. The corrosive sublimate was found to be reduced to the state of calomel; and, hence, it may be inferred that half the chlorine of the former united with the quinia. This preparation has been found useful in the treatment of obstinate skin diseases, given in the dose of a grain two or three times a day.

CHLORIDE OF POTASSA, SOLUTION OF. *Liquor Potassæ Chlorinatæ. Javelle's Water. Eau de Javelle.* This is obtained precisely as the solution of chlorinated soda. (See *Liquor Sodæ Chlorinatæ.*) It is employed for taking out fruit stains, &c., from linen. In chemical constitution it is probably a hypochlorite.

CHLORIDE OF SILVER. *Argenti Chloridum.* This has been already referred to as being inevitably formed when nitrate of silver is given internally. (See *page* 898.) It is readily prepared by adding a solution of common salt to one of nitrate of silver, as long as it produces a precipitate. As first thrown down it is a white curdy substance, but it soon becomes discoloured when exposed to the light. It has been used, rubbed on the tongue, in syphilis, and internally in epilepsy, chronic dysentery and diarrhœa, and other diseases in which nitrate of silver has been given. The dose is from one to three grains or more, four or five times a day. Dr. Perry administered it at the Philadelphia hospital, Blockley, in chronic dysentery, with the immediate effect of diminishing the number of stools. The crystallized *ammonio-chloride of silver* has been given in syphilitic affections, in the dose of the fourteenth of a grain. It is formed by saturating solution of ammonia, by the aid of heat, with chloride of silver, and allowing the liquid to cool in a stopped bottle. It crystallizes in cubes, and is very liable to decomposition.

CHLORINATED ANÆSTHETIC COMPOUNDS. By the mutual action of chlorine and olefiant gas, an oily liquid is obtained, discovered by the associated Dutch chemists, and called *Dutch liquid*, or *chloride of olefiant gas*. The empirical formula of this compound is $C_4H_4Cl_2$; the rational C_4H_3Cl,HCl. When it is acted on by an alcoholic solution of potassa, muriatic acid is separated by the formation of chloride of potassium, and a compound represented by C_4H_3Cl is set free. By the action of additional chlorine, the Dutch liquid is susceptible of having each equivalent of hydrogen successively replaced by one of chlorine, forming four new compounds; namely, $C_4H_2Cl_2,HCl$—C_4HCl_3,HCl—C_4Cl_4,HCl—C_4Cl_6. The last compound here is evidently a 6–4 chloride of carbon; and the others are called by Regnault, in allusion to the replacing chlorine, without noting the disappearing hydrogen, monochlorinated, bichlorinated, and trichlorinated Dutch liquid. The Dutch liquid has been tried as an anæsthethic by Dr. Simpson and Mr. Nunnely. Dr. Simpson was not satisfied with its effects; but Mr. Nunnely, having administered it frequently in practice, found it perfectly agreeable in every respect. Its use is not attended by the troublesome excitement produced by ether, or by the tendency to collapse caused by chloroform. Two forms of Dutch liquid have been recently experimented with by Dr. Aran, of Paris; and one of them furnished satisfactory clinical results. The liquid which gave favourable results has been ascertained by Mialhe and Flourens to be the monochlorinated Dutch liquid; but its cost proved to be too high to allow of its general use as a therapeutic agent. In consequence of this objection to the liquid just named, Mialhe and Flourens were induced to search for a substitute in the corresponding compound of a parallel series of ethers, formed by the action of chlorine on muriatic ether. When muriatic ether (C_4H_5Cl) is acted on by successive portions of chlorine, the hydrogen is replaced by the latter, equivalent for equivalent, and there are formed the five following compounds; $C_4H_4Cl_2$—$C_4H_3Cl_3$—$C_4H_2Cl_4$—C_4HCl_5—C_4Cl_6. Of this series, the first member is isomeric with the Dutch liquid; the second, third, and fourth with the mono- bi- and trichlorinated Dutch liquid, and the fifth is the 6–4 chloride of carbon, the terminating compound of the other series. The first member, though identical with the Dutch liquid in elementary composition, and having a vapour of the same density, has, nevertheless, a lower boiling point, and is different in chemical properties. Thus, it is not decomposed by an alcoholic solution of potassa, as the Dutch liquid is; and is not acted on by potassium, while the Dutch liquid is immediately attacked by it. These facts show that the atomic constitution of these two substances must be different. In like manner the second, third, and fourth members of this series are different in chemical properties from their isomeric representatives in the Dutch liquid series. In denoting the different degrees of chlorination of the muriatic ether series, Regnault indicates merely (as in the Dutch liquid series) the number of eqs. of chlorine supposed to replace hydrogen. Accordingly, he calls the first member of the series monochlorinated muriatic ether, corresponding to the Dutch liquid; and the second, third, and fourth, bi- tri- and quadrichlorinated muriatic ethers, corresponding to the mono- bi- and trichlorinated Dutch liquids. This confusion of nomenclature arises from the fact that the replacement by chlorine sets out from five eqs. of hydrogen in the muriatic ether series, and from four eqs. in the Dutch liquid series.

From the explanation above given, it will be understood that the compound of the muriatic ether series corresponding to the monochlorinated Dutch liquid, is the bichlorinated muriatic ether. This compound proved too volatile to act advantageously as a local anæsthetic. The tri- and quadrichlorinated ethers are denser and less volatile, and acted more favourably. The conclusion arrived at by Mialhe and Flourens appears to be that the four chlorinated muriatic ethers all possess anæsthetic properties; and as it would be difficult to separate them, they propose the use of the mixed ethers, consisting principally of the tri- and quadrichlorinated compounds, as an anæsthetic, under the indefinite name of chlorinated muriatic ether (*chlorinated chlorohydric ether*).

Chlorinated muriatic ether is a colourless, very mobile, neuter liquid, having an aromatic ethereal odour, and hot saccharine taste. It is sparingly soluble in water, but readily soluble in alcohol, ether, and most of the fixed and volatile oils. It is not inflammable, in which respect it agrees with chloroform. Being a mixture of different liquids, its sp. gr. is not uniform. Its boiling point varies from 230° to 266°. According to the experiments of Flourens, it has a similar action to chloroform, the most important of the chlorinated anæsthetics. (See *chloroformum*). Its local action is that of a powerful sedative. (B. Cucuel, *Ann. de Thérap.*, 1853, 102.)

CHROME YELLOW. This is the neutral chromate of lead, prepared by precipitating a solution of the nitrate of lead with chromate of potassa. It is of a beautiful lemon-yellow colour. The subchromate of lead, consisting of one eq. of acid, and two eqs. of base, is of a red colour, and is sometimes used as a pigment. *Chrome green* is a mixture of chrome yellow and Prussian blue.

CHROMIC ACID. *Acidum Chromicum.* This acid is readily obtained by mixing 100 measures of a cold saturated solution of bichromate of potassa with 150 measures of sulphuric acid, and allowing the mixture to cool. The sulphuric acid unites with the potassa, and sets the chromic acid free, which crystallizes in brilliant crimson-red prisms. The mother-liquor having been poured off, the crystals should be placed upon a tile to drain, covered with a glass bell-jar. Chromic acid is deliquescent and very soluble in water. It is a powerful oxidizer, yielding its oxygen readily to organic matter, which is thereby dissolved. In composition it is the teroxide of chromium, having the formula CrO_3. This acid has been tried as a caustic by Prof. Sigmund, of Vienna, on the recommendation of Dr. Heller. Used in substance, made into a paste with water, its action is exceedingly slow and gradual, but deeply penetrating. In saturated solution its action is less penetrating and less gradual. By using a solution more or less dilute, the action may be graduated according to the degree of effect desired. Prof. Sigmund tried the concentrated solution, with advantage, for the destruction of condylomata, occurring in his syphilitic wards. This caustic is well suited to the destruction of morbid growths, and gives less pain than other caustics. Chromic acid acts as a rapid solvent of organic matter. "Smaller animals (mice, birds, &c.) were so completely dissolved by the acid within fifteen or twenty minutes, that no trace of their bones, skin, hair, claws, or teeth could be discovered." (*Dublin Quarterly Journ.*, xiii. 250, from the *Wiener Medizinische Wochenschrift.*)

CICHORIUM INTYBUS. *Chicory. Succory.* A perennial herbaceous plant, indigenous in Europe, but naturalized in this country, where it grows in fields, and in roads along the fences, in neighbourhoods which have been long settled. It is one or two feet high, with large, compound, beautifully blue flowers, which appear in July and August, and serve to distinguish the plant at first sight. The whole plant has a bitter taste, without acrimony, or any very peculiar flavour. The taste is strongest in the root, and weakest in the flowers. The leaves, when young and tender, are said to be sometimes eaten as salad in Europe. Succory is gently tonic without being irritating, and is considered by some authors as aperient and deobstruent. It is said to be useful, if freely taken, in hepatic congestion, jaundice, and other visceral obstructions in the early stages: and is affirmed to have done good even in pulmonary consumption. The usual form of administration is that of decoction, which is prepared by boiling one or two ounces of the root, or a handful of the herb, in a pint of water. The root dried and roasted is much used in certain parts of Europe as a substitute for coffee, and is said also to be mixed fraudulently with ground coffee for sale. In preparing it for coffee, Dausse recommends that the dried root should be cut into rather large and equal pieces, which are to be roasted until they lose 140 out of 500 parts. The pieces are then easily ground in a mill, and afford a yellowish-brown powder. (*Pharm. Cent. Blatt*, Oct. 1850, p. 688.) The *garden endive* is a species of Cichorium, denominated *C. Endivia.*

CICUTA VIROSA. *Water Hemlock. Cowbane.* A perennial, umbelliferous European plant, growing on the borders of pools and streams. It is very poisonous, proving fatal to most animals which feed upon it, though said to be eaten with impunity by goats and sheep. Several instances are on record of children who have died from eating the root by mistake for parsnep. It operates as an acrid narcotic, producing inflammation of the stomach, together with symptoms which indicate cerebral disturbance, such as vertigo, intoxication, and convulsions. Infusion of galls is recommended as an antidote, but should not be relied on to the exclusion of emetics. When the plant vomits, as it frequently does, fatal effects are less apt to ensue. It is said to be less poisonous dried than fresh; and it has been inferred that the active principle is volatile. But the volatile oil, obtained by distillation, was found by Simon, of Berlin, not to be poisonous. On the other hand, the alcoholic extract of the dried root operated as a violent poison upon animals. (*Annal. der Pharm.*, xxxi. 258.) It is at present never used internally, having been superseded by

Conium maculatum. Externally it is sometimes employed as an anodyne poultice in local pains, particularly those of a rheumatic or gouty nature.

The *Cicuta maculata* or *American water hemlock* is closely analogous, in botanical character and effects, to the European species. In several instances, children have been fatally poisoned by eating its root. It is never used in medicine. For a full account of this plant, see *Bigelow's Medical Botany* (i. 125). In cases of poisoning by either of these plants, vomiting should be induced as speedily as possible, and maintained till the stomach is thoroughly evacuated.

CITRATE OF IRON AND MAGNESIA. *Ferri et Magnesiæ Citras.* This double salt has been introduced to the notice of the profession by M. Van der Corput. It is made by dissolving two ounces of freshly precipitated hydrated oxide of iron in a moderately heated solution of three ounces of citric acid, and saturating the liquor with carbonate of magnesia. The solution, after filtration, is evaporated by means of a water-bath to a syrupy consistence, and spread on glass to dry in scales. The carbonate required is nearly an ounce. Three and a quarter ounces of sulphate of iron will furnish by decomposition the necessary hydrated oxide for three ounces of the acid. (See formula for *Ferri Oxidum Hydratum*.) This salt is in transparent greenish-yellow scales, having a slightly ferruginous somewhat acid taste. It is very soluble in water, but insoluble in alcohol and ether. It may be given in doses of five or ten grains, in the form of solution, syrup, or pill. (See the remarks of Prof. Procter on this preparation, contained in the *Am. Journ. of Pharm.* for Oct. 1850, p. 315.)

CITRATE OF IRON AND QUINIA. *Ferri et Quiniæ Citras.* This is made, according to Prof. Procter, by heating together, in a capsule, *an ounce* of recently precipitated quinia, *two drachms* of citric acid, *five ounces* of citrate of iron, and *twelve fluidounces* of water, constantly stirring, and avoiding ebullition. When the solution is effected, evaporate carefully to a syrupy consistence, and spread on glass to dry in thin layers. This double salt is in the form of shining scales, of a garnet-red colour, more or less deep. It is given as a tonic in doses of five grains or more, three times a day, either in solution, or in the form of pill. This double salt is sometimes adulterated with cinchonia, which replaces part of the quinia. A sample, analyzed by Mr. C. G. Williams, was found to contain only 5·3 per cent. of quinia, instead of 12·5 per cent. (*Chem. Gaz.*, xi. 269.)

CITRATE OF SODA. *Sodæ Citras.* This salt may be formed by saturating a solution of citric acid with bicarbonate of soda, evaporating the liquid, and setting it aside to crystallize. It is a white salt crystallized in six-sided pyramids, and having a saline taste without any bitterness. Citrate of soda has been proposed by M. Guichon, of Lyons, as a pleasant purgative, having properties similar to those of citrate of magnesia, and, though possessing a taste more decidedly saline than the latter, having the advantages of cheapness, and of a constant solubility, which permits it to be associated with other medicinal preparations. The dose is from ten to fourteen drachms, given in simple aqueous solution, or acidulated with citric acid and sweetened.

CIVET. *Zibethum.* This is an odorous substance, obtained from two animals of the genus Viverra, viz., the *V. Civetta* or civet cat of Africa, and the *V. Zibetha* which inhabits the East Indies. It is secreted into a cavity which opens between the anus and external genitals, and is collected from animals confined for the purpose. It is semi-liquid, unctuous, yellowish, becoming brown and thicker by exposure to the air, of a very strong, peculiar odour, similar to that of musk, though less agreeable and less diffusible, and of a bitterish, subacrid, disagreeable, fatty taste. When heated it becomes quite fluid, and at a higher temperature takes fire, and burns with a clear flame, leaving little residue. It is insoluble in water, and only slightly soluble in ether and cold alcohol; but heated alcohol dissolves it almost entirely, depositing it again upon cooling. It contains, among other ingredients, a volatile oil, fat, and free ammonia. In medicine it was formerly employed as a stimulant and antispasmodic, like castor and musk; but it is now used exclusively as a perfume.

CLEMATIS ERECTA. *Upright Virgin's Bower.* A perennial European plant. The leaves and flowers have an acrid burning taste. When bruised in a mortar they irritate the eyes and throat, giving rise to a flow of tears and to coughing; and applied to the skin they produce inflammation and vesication. Hence the name of *flammula Jovis*, by which the plant was known in older pharmacy. The acrimony is greatly diminished by drying. Störck found this species of Clematis useful in secondary syphilis, cancerous and other foul ulcers, and severe headaches. He gave it internally, and at the same time applied the powdered leaves to the surface of the sore. It acted as a diuretic and diaphoretic. Two or three drachms of the leaves were infused in a pint of water, of which he administered four ounces three times a day. He also employed an extract, in the dose of a grain or two in the course of a day. At present the plant is not used.

Other species of Clematis have the same acrid properties. Among these are *C. Flammula* or *sweet scented virgin's bower*, which, though a native of Europe, is cultivated in our gardens, *C. Vitalba* or *traveller's joy*, also a native of Europe, and several indigenous species, of which *C. Virginica* or *common virgin's bower*, *C. Viorna* or *leather flower*, and *C. crispa* have been particularly cited by authors as proper substitutes for the C. erecta used by Störck. All these are climbing plants. C. Vitalba has been used in Europe with success in the cure of itch. For this purpose the roots and stems, bruised, and boiled for a short time to diminish their acrimony, were infused in boiling oil, which, thus impregnated, was applied to the skin several times a day. Twelve or fifteen applications were usually sufficient.

COBALT BLUE. This beautiful pigment is a compound of oxide of cobalt and alumina, obtained by precipitating the mixed solutions of a salt of alumina and of cobalt by means of an alkali, and washing, drying, and strongly calcining the precipitate. (*Berzelius.*) The cobalt blue of Thenard is made by heating together the hydrated subphosphate of cobalt and hydrate of alumina. It is used in painting. An oxide of cobalt prepared by precipitating the chloride with potassa has been employed in rheumatism. It is emetic in the dose of 10 or 20 grains. The salts of the metal are irritant poisons.

COBWEB. *Spider's Web. Tela Araneæ.* The genus *Aranea* of Linn. has been divided by subsequent naturalists into several genera, of which the *Tegeneria* of Walkenaer is the one that includes the medicinal species of spider. The *T. domestica* of Europe, and *T. medicinalis* of this country (Henz, *Journ. Acad. of Nat. Sci.*, ii. 53), are the particular species which have attracted most attention. They inhabit cellars, barns, and other dark places, and are of a brown or blackish colour. It is affirmed that the web of the field spider is inefficacious, while that collected in the cellars of houses, &c., has extraordinary medical virtues. Several authors speak in very decided terms of its powers as a febrifuge and antispasmodic. According to Dr. Robert Jackson, it is superior even to bark and arsenic in the cure of intermittents, and is, moreover, highly useful in various spasmodic and nervous diseases, controlling and tranquillizing irregular nervous action, exhilarating the spirits, and disposing to sleep, without producing any of the narcotic effects of opium on the brain. Among the complaints in which it has been found useful, besides intermittent fever, are periodical headache, hectic fever, asthma, hysteria, and nervous irritations attended with morbid vigilance and irregular muscular action. It will be observed that these are, for the most part, affections over which the imagination has much control. The dose of spider's web is five or six grains, to be given in the form of pill, and repeated every three or four hours. Dr. Jackson states that its influence is not in proportion to the quantity administered, and that he obtained the same effects from ten as from twenty grains. This might well be, if the supposition be allowed that its chief operation is through the imagination. Spider's web has also been used, with asserted advantage, as a styptic in wounds, and a healing application in superficial ulcers. Spiders themselves were formerly employed in the treatment of intermittent fever, and this application of the web is not of recent origin.

COCHLEARIA OFFICINALIS. *Common Scurvy-grass.* This is an annual or biennial plant, sending up early in the spring a tuft of radical leaves, which are heart-shaped, roundish, of a deep shining-green colour, and supported on long footstalks. The leaves of the stem are alternate, oblong, somewhat sinuate, the lower petiolate, the upper sessile. The stem is erect, branched, angular, six or eight inches high, and bears, at the extremity of the branches, numerous white cruciform peduncled flowers, in thick clusters. The fruit is a roundish two-celled pod, containing numerous seeds. The whole plant is smooth and succulent. It is a native of the northern countries of Europe, where, as well as in the United States, it is occasionally cultivated in gardens. The whole herb is officinal. It has, when fresh, a pungent unpleasant odour if bruised, and a warm, acrid, bitter taste. These properties are lost by drying. They are imparted to water and alcohol by maceration, are retained by the expressed juice, and probably depend on a peculiar volatile oil which is separable in very small quantity by distillation with water.

Common scurvy-grass is gently stimulant, aperient, and diuretic. It is highly celebrated as a remedy in sea-scurvy, and has been recommended in chronic obstructions of the viscera, and certain forms of chronic rheumatism. The fresh plant may be eaten as a salad, or used in the form of infusion in water or wine, or of the expressed juice. Alcohol and water are impregnated with its virtues by distillation; and the distilled spirit has been found useful in paralysis, in the dose of thirty drops several times a day. The expressed juice may be used as a local application in scorbutic affections of the gums.

COCOA. *Cacao. Chocolate Nuts.* These are the seeds of *Theobroma Cacao*, a handsome tree, from twelve to twenty feet in height, growing in Mexico, the West Indies, and South America, in some parts of which it is largely cultivated, particularly in Guayaquil

and Venezuela. The fruit is an oblong-ovate capsule or berry, six or eight inches in length, with a thick, coriaceous, somewhat ligneous rind, enclosing a whitish pulp, in which numerous seeds are embedded. These are ovate, somewhat compressed, about as large as an almond, and consist of an exterior thin shell, and a brown oily kernel. Separated from the matter in which they are enveloped, they constitute the *cocoa* of commerce. They have a slightly aromatic, bitterish, oily taste, and, when bruised or heated, an agreeable odour. They contain a large quantity of fixed oil, together with albumen and bitter extractive. The oil is obtained by hot expression, or by decoction. It is a soft solid, whitish or yellowish, with a peculiar agreeable odour, and a bland pleasant taste, and is known by the name of *cocoa butter*. According to Brandes, it has peculiar properties, and yields a peculiar acid when saponified. He calls the oil *cocin*, and the acid *cocinic acid*. (*Journ. de Pharm.*, xxiv. 652.) It has since been found to contain several solid and volatile fatty acids; as caproic, caprylic, capric, and pichuric acids. (*Ibid.*, 3*e sér.*, xv. 69.) The oil is said to be frequently adulterated with animal fats. The chief use to which it is applied is as an ingredient in cosmetic unguents. A peculiar crystallizable azotized principle, called *theobromin*, has been found in the seeds by M. Woskresensky. It is said to contain a larger proportion of nitrogen than cafeïn. (*Journ. de Pharm.*, 3*e sér.*, i. 136.) The shells of the nuts are sometimes employed in the state of infusion, as a substitute for tea or coffee. They impart to boiling water a taste analogous to that of chocolate, but weaker. The kernel is consumed in great quantities, in the shape of chocolate, or in some analogous form.

Chocolate is differently prepared in different countries. In Great Britain and the United States, it usually consists, when pure, exclusively of the cocoa or chocolate nuts, which are first roasted, then deprived of their shell, and lastly reduced, by grinding between heated stones, to the state of a paste, which is moulded into oblong cakes. Not unfrequently rice flour or other farinaceous substance, with butter or lard, is added; but these must be considered as adulterations. On the continent of Europe, sugar is generally incorporated with the paste, and spices, especially cinnamon, are often added. Vanilla is a favourite addition in South America, France, and Spain. Cocoa is often sold in the state of powder, which is sometimes mingled with other ingredients, such as ground rice, barley flour, sugar, &c. Chocolate is prepared for use by reducing it to powder, and boiling it in milk, water, or a mixture of these fluids. In this state it is much employed as a drink at the morning and evening meals, and serves as an excellent substitute for coffee in dyspeptic cases. It is also a good article of diet for convalescents, and may sometimes be given advantageously as a mild nutritive drink in acute disease.

COFFEE. The coffee plant—*Caffea Arabica*—belongs to the class and order Pentandria Moñogynia of the sexual system, and to the natural order Cinchonaceæ of Lindley. It is a small tree, rising from fifteen to thirty feet in height. The branches are opposite, the lower spreading, the upper somewhat declining, and gradually diminishing in length as they ascend, so as to form a pyramidal summit, which is covered with green foliage throughout the year. The leaves are opposite, upon short footstalks, oblong-ovate, acuminate, entire, wavy, four or five inches long, smooth and shining, of a dark-green colour on their upper surface, paler beneath, and accompanied with a pair of small pointed stipules. The flowers are white, with an odour not unlike that of the jasmine, and stand in groups in the axils of the upper leaves. The calyx is very small, the corolla salverform, with a nearly cylindrical tube, and a flat border divided into five lanceolate, pointed segments. The stamens project above the tube. The fruit, which is inferior, is a roundish berry, umbilicate at top, at first green, then red, and ultimately dark-purple. It is about as large as a cherry, and contains two seeds surrounded by a paper-like membrane, and enclosed in a yellowish pulpy matter. These seeds, divested of their coverings, constitute coffee.

This tree is a native of Southern Arabia and Abyssinia, and probably pervades Africa about the same parallel of latitude, as it is found growing wild at Liberia, on the western coast of the continent. It is cultivated in various parts of the world where the temperature is sufficiently elevated and uniform. Considerable attention has long been paid to its culture in its native country, particularly in Yemen, in the vicinity of Mocha, from which the demands of commerce were at first almost exclusively supplied. About the year 1690, it was introduced by the Dutch into Java, and in 1718, into their colony of Surinam. Soon after this latter period, the French succeeded in introducing it into their West India Islands, Cayenne, and the Isles of France and Bourbon; and it has subsequently made its way into the other West India Islands, various parts of tropical America, Hindostan, and Ceylon.

The tree is raised from the seeds, which are sown in a soil properly prepared, and, germinating in less than a month, produce plants which, at the end of the year, are large enough to be transplanted. These are then set out in rows at suitable distances, and in three or four years begin to bear fruit. It is customary to top the trees at this age, in order to prevent their attaining an inconvenient height, and to increase the number of

fruit-bearing branches. It is said that they continue productive for thirty or forty years. Though almost always covered with flowers and fruit, they yield most abundantly at two seasons, and thus afford two harvests during the year. Various methods are employed for freeing the seeds from their coverings; but that considered the best, is by means of machinery to remove the fleshy portion of the fruit, leaving the seeds surrounded only by their papyraceous envelope, from which they are afterwards separated by drying, and by the action of peeling and winnowing mills.

The character of coffee varies considerably with the climate and mode of culture. Consequently, several varieties exist in commerce, named usually from the sources from which they are derived. The *Mocha coffee*, which is in small roundish grains, takes precedence of all others. The *Java coffee* is highly esteemed in this country; but our chief supplies are derived from the West Indies and South America. Some good coffee has been brought from Liberia. Coffee improves by age, losing a portion of its strength, and thus acquiring a more agreeable flavour. It is said to be much better when allowed to become perfectly ripe upon the tree, than as ordinarily collected. The grains should be hard, and so heavy as readily to sink in water. When soft, light, black or dark-coloured, or musty, they are inferior.

Coffee has a faint, peculiar odour, and a slightly sweetish, somewhat austere taste. An analysis by M. Payen gives for its constituents, in 100 parts, 34 of cellulose, 12 of hygroscopic water, 10 to 13 of fatty matter, 15·5 of glucose, with dextrine and a vegetable acid, 10 of legumin, 3·5 to 5 of *chlorogenate of potassa and caffein*, 3 of a nitrogenous body, 0·8 of free caffein, 0·001 of concrete volatile oil, 0·002 of fluid volatile oil, and 6·697 of mineral substances. (*Journ. de Pharm.*, 3*e sér.*, x. 266.) Pfaff recognised, in the precipitate produced by acetate of lead with the decoction of coffee, two peculiar principles, one resembling tannin, called *caffeo-tannic acid*, and the other an acid, called by him *caffeic acid*. *Caffein* was first discovered by Runge, and afterwards by Robiquet. According to Payen it exists in the coffee partly free, partly in the form of a double salt, consisting of a peculiar acid, denominated *chlorogenic acid*, combined with potassa and caffein. It may be obtained in the following manner. Exhaust bruised coffee by two successive portions of boiling water, unite the infusions, add acetate of lead, in order to precipitate the principles which accompany the caffein, filter, decompose the excess of acetate of lead in the filtered liquor by sulphuretted hydrogen, concentrate by evaporation, and neutralize with ammonia. The caffein is deposited in crystals upon cooling, and may be purified by redissolving in water, treating with animal charcoal, and evaporating. For another method, said to be more economical, proposed by H. J. Versmann, of Lubeck, the reader is referred to the *Chemical Gazette* (Feb. 16, 1852, p. 67). Caffein crystallizes, by the cooling of its concentrated solution, in opaque, silky, flexible needles: by slow and spontaneous evaporation, in long transparent prisms. It has a feebly bitter and disagreeable taste, is soluble in water, alcohol, and ether, melts when exposed to heat, and at a higher temperature sublimes, without residue, in needles analogous to those formed by benzoic acid. It is precipitated from its aqueous solution by no reagent except tannic acid, and is remarkable for containing a larger proportion of nitrogen than almost any other proximate vegetable principle, in this respect equalling some of the most highly animalized products. The present views of its composition are represented by the formula $N_2C_8H_5O_2$; and it is believed to be identical with theïn, or the peculiar principle of tea. Notwithstanding its large proportion of nitrogen, caffein does not putrefy, even when its solution is kept for some time in a warm place.

Coffee undergoes considerable change during the roasting process. It swells up very much, acquiring almost double its original volume, while it loses from 15 to 20 per cent. of its weight. (*Pharm. Cent. Blatt*, Oct. 1850, p. 687.) It acquires, at the same time, a peculiar odour entirely different from that of the unaltered grains, and a decidedly bitter taste. A volatile oil is developed during the process, and, according to Chenevix, a portion of tannin. The *caffein* does not appear to undergo material change, as, according to Garot, it may be extracted unaltered from the roasted coffee. The excellence of the flavour of roasted coffee depends much upon the manner in which the process is conducted, and the extent to which it is carried. It should be performed in a covered vessel, over a moderate fire, and the grains should be kept in constant motion. When they have acquired a chestnut-brown colour, the process should cease. If too long-continued, it renders the coffee bitter and acrid, or, by reducing it to charcoal, deprives it entirely of flavour. The coffee should not be burnt long before it is used, and should not be kept in the ground state.

Medical and Economical Uses.—More attention has been paid to the effects of coffee on the system in the roasted than in the crude state. Unroasted coffee has been employed by Dr. Grindel, of Russia, in intermittent fever, and the practice has been followed by other physicians; but the success, though considerable, has not been such as to lead to the conclusion that this medicine would answer as a substitute for Peruvian bark. It was given

in powder, in the dose of a scruple every hour, in decoction prepared by boiling an ounce with eighteen ounces of water down to six, or in the state of extract in the dose of from four to eight grains.

The action of coffee is directed chiefly to the nervous system. When swallowed it produces a warming cordial impression on the stomach, quickly followed by a diffused agreeable nervous excitement, which extends itself to the cerebral functions, giving rise to increased vigour of imagination and intellect, without any subsequent confusion or stupor such as characterizes the action of narcotic medicines. Indeed, one of its most extraordinary effects is a disposition to wakefulness, which continues for several hours after it has been taken. It is even capable of resisting, to a certain extent, the intoxicating and soporific influence of alcohol and opium, and may sometimes be advantageously employed for this purpose. It also moderately excites the circulatory system, and stimulates the digestive function. A cup of coffee, taken after a hearty meal, will often relieve the sense of oppression so apt to be experienced, and enable the stomach to perform its office with comparative facility. The exhilarating effects of coffee, united with its delicious flavour when suitably qualified by cream and sugar, have given rise to its habitual employment as an article of diet. Its use for this purpose has prevailed from time immemorial in Persia and Arabia. In 1517 it was introduced by the Turks into Constantinople, whence it was carried to France and England about the middle of the succeeding century, and has since gradually made its way into almost universal use. It cannot be supposed that a substance capable of acting so energetically upon the system, should be entirely destitute of deleterious properties. Accordingly, if taken in very large quantities, it leaves, after its first effects are passed, a degree of nervous derangement or depression equivalent to the previous excitement; and its habitual immoderate employment is well known very greatly to injure the tone of the stomach, and frequently to give rise to troublesome dyspeptic and nervous affections. This result is peculiarly apt to take place in individuals of susceptible nervous systems, and in those of sedentary habits. We have repeatedly known patients, who have long suffered with headache and vertigo, to get rid of them by abstaining from coffee.

In the treatment of disease, coffee has been less employed than might have been expected from its effects upon the system. There can be no doubt that it may be advantageously used in various nervous disorders. In a tendency to stupor or lethargy dependent on deficient energy of the brain, without congestion or inflammation, it would be found useful by stimulating the cerebral functions. In light nervous headaches, and even in sick headache not caused by the presence of offending matter in the stomach, it often proves temporarily useful. It has acquired much reputation as a palliative in the paroxysms of spasmodic asthma, and has been recommended in hooping-cough, and in hysterical affections. The Egyptians are said to have formerly employed it as a remedy in amenorrhœa. Hayne informs us that in a case of violent spasmodic disease, attended with short breath, palpitation of the heart, and a pulse so much increased in frequency that it could scarcely be counted, immediate relief was obtained from a cup of coffee, after the most powerful antispasmodics had been used in vain for several hours. By the late Dr. Dewees it was highly recommended in cholera infantum. It is said also to have been used successfully in obstinate chronic diarrhœa; and the late Dr. Chapman, of Philadelphia, found it highly useful in calculous nephritis. We have heard of its effectual use in croup. In acute inflammatory affections it is contra-indicated. It should be given in cases of poisoning from opium, after the evacuation of the stomach, or when from any cause such evacuation is not effected.

Coffee is usually prepared in this country by boiling the roasted grains, previously ground into a coarse powder, in water for a short time, and then clarifying by the white of an egg. Some prefer the infusion, made by a process similar to that of displacement. It has more of the aroma of the coffee than the decoction, with less of its bitterness. The proper proportion for forming the infusion for medical use is an ounce to a pint of boiling water, of which a cupful may be given warm for a dose, and repeated, if necessary. *Citrate of caffein*, made by dissolving caffein in a solution of citric acid with a gentle heat, and evaporating carefully, has been recommended as a preventive and remedy in sick headache, in the dose of a grain every hour, before or during the paroxysm.

The *leaves* of the coffee plant possess properties analogous to those of the fruit, and are extensively used, in the form of infusion, as a beverage, in the vicinity of Padang in the island of Sumatra. An account of their employment was published in the *Singapore Free Press* by Mr. N. M. Ward, of Padang. Previously to this, Dr. John Gardener, of London, had proposed to introduce them into use in Europe, and is stated to have taken out a patent for the mode of preparing them. A specimen examined by Dr. Stenhouse has been found to contain caffein in larger proportion than the coffee-bean, and also caffeic acid. Mr. Ward states that, in Sumatra, the leaves are prepared for use by moderately roasting them, and then powdering them coarsely by rubbing in the hands. The powder

is made into an infusion like common tea. The taste is said to be like that of tea and coffee combined. (*Pharm. Journ. and Trans.*, xii. 443, and xiii. 207 and 382.)

COLLINSONIA CANADENSIS. *Horse-weed. Horse-balm. Richweed. Heal-all. Stone-root. Knot-root.* An indigenous plant, with a perennial, knotty root, and an herbaceous simple stem about two feet high, furnished with two or three pairs of broad, cordate-ovate, smooth leaves, and terminating in a panicle of yellow flowers in branched racemes. The flowers are diandrous and monogynous, with a labiate calyx and corolla, the latter of which has the lower lip fringed. The plant grows in woods from Canada to Carolina, and flowers from July to September. The whole plant has a strong disagreeable odour, and a warm pungent taste. It is considered tonic, astringent, diaphoretic, and diuretic; and the root, in substance, is said to irritate the stomach, and produce vomiting, even in small doses. The plant is used in numerous complaints in domestic practice. It is preferred in the fresh state, as the active principle is volatile. A decoction of the fresh root is said to have been used with advantage in catarrh of the bladder, leucorrhœa, gravel, dropsy, and other complaints; and the leaves are applied by the country people, in the form of cataplasm or fomentation, to wounds, bruises, and sores, and in cases of internal abdominal pains.

COLUTEA ARBORESCENS. *Bladder Senna.* A shrub, growing spontaneously in the southern and eastern parts of Europe, and cultivated in gardens as an ornamental plant. Its leaves are pinnate, consisting of from three to five pairs of leaflets, with an odd one at the end. The leaflets are obovate, slightly emarginate, smooth, and of a deep-green colour on the upper surface, grayish-green and somewhat pubescent beneath. The flowers are yellow, and the fruit vesicular, whence the plant derived its vulgar name. The leaflets are purgative, and, in some parts of Europe, are used as a substitute for senna, which is said to be sometimes adulterated with them. Bladder senna is comparatively very feeble. It is administered in infusion or decoction, of which the dose is about half a pint, containing the virtues of from one to three ounces of the leaves.

COMPTONIA ASPLENIFOLIA. *Sweet Fern.* A shrubby indigenous plant, named from the resemblance of its leaves to the *spleenwort fern*, but belonging to the Linnæan class and order *Monœcia Triandria.* It grows in thin sandy or stony woods, from New England to Virginia. All parts of it possess a resinous spicy odour, which is increased when the plant is rubbed. It is said to be tonic and astringent, and to be occasionally used in domestic practice as a remedy in diarrhœa, and various other complaints. It is employed in the form of decoction.

CONVALLARIA MAJALIS. *Lily of the Valley.* This charming little garden flower is a native of Europe, and is found growing wild in the United States, upon the highest mountains of Virginia and Carolina. The *flowers* have a strong delightful odour, which is in great measure lost by drying. Their taste is nauseous, bitter, and acrid. Taken internally they are said to be emetic and cathartic, and their extract purges actively in the dose of half a drachm. They were formerly used in epilepsy and against worms. At present they are employed only as a sternutatory, for which purpose they are dried and reduced to a coarse powder. The *root*, which is also bitter, has similar purgative properties, and, reduced to powder, is said to be sternutatory.

CONVALLARIA POLYGONATUM. Linn. *Polygonatum uniflorum.* Desfontaines. *Solomon's Seal.* A perennial, herbaceous, European plant, the root of which is horizontal, jointed, white, and marked, at short intervals, with small circular impressions, which bear a remote resemblance to those made by a seal, and have served to give a name to the plant. The root is inodorous, and of a sweetish mucilaginous taste, followed by a slight degree of bitterness and acrimony. It is said to be emetic. In former times it was used externally in bruises, especially those about the eyes, in tumours, wounds, and cutaneous eruptions, and was highly esteemed as a cosmetic. At present it is not employed, though recommended by Hermann as a good remedy in gout and rheumatism. The berries and flowers are said to be acrid and poisonous. *C. multiflora* (*Polygonatum multiflorum*, Desf.), which grows both in this country and Europe, is analogous to the preceding in properties. Dr. John H. Rauch found two fluidounces of a decoction, made by boiling two ounces of the root in a pint of milk, to produce nausea, a cathartic effect, and either diaphoresis or diuresis. He used it advantageously as an internal remedy in piles, and externally, in the form of decoction, in the affection of the skin resulting from the poisonous exhalations of certain plants. (*Inaugural Essay*, March, 1849.)

COPAL. A resinous substance, brought from the East Indies, South America, and the western coast of Africa, but most abundantly from the first mentioned source. It is the concrete juice of different trees, and is furnished by exudation. The East Indian copal has been ascribed by some writers to the *Vateria Indica* of Linn., the *Elæocarpus copal-*

iferus of Retzius; and the Brazilian, by Martius and Hayne, probably with justice, to different species of *Hymenæa*. There is some reason to believe that the East India copal is also the product of a Hymenæa; at least a specimen of this resin was collected by M. Perottet from the *Hymenæa verrucosa*, which he found growing in the Isle of Bourbon. This tree is a native of Madagascar, and probably of the neighbouring parts of Africa; and M. Perottet was informed that the copal of India is taken thither by the Arabs of Muscat, who obtain it from the East coast of Africa. (*Journ. de Pharm.*, *3e sér.*, i. 406.) It is stated by Mr. James Vaughan, who was stationed as army surgeon at Aden, in Arabia, that copal is taken to that port from the African coast opposite the island of Zanzibar, where it is said to be dug up from the earth. (*Pharm. Journ. and Trans.*, xii. 385.) Copal varies somewhat in appearance and properties, as procured from different sources. It is in roundish, irregular, or flattish pieces, colourless, yellowish, or brownish-yellow, more or less transparent, very hard, with a shining conchoidal fracture, inodorous and tasteless, of a sp. gr. varying from 1·045 to 1·139, insoluble in alcohol, soluble in ether, and slightly so in oil of turpentine. Some varieties unite with alcohol, if suspended in its vapour while boiling. By heat it melts and is partially decomposed, becoming thereby soluble in alcohol and oil of turpentine. It is not a proximate principle, but consists of various resins united in different proportions. The East India or African copal is described by Mr. Schindler as of a globular form, softer and more transparent than the other varieties, with a surface always clear, and having an agreeable smell when heated. It is readily and freely dissolved by the oils of turpentine and rosemary when pure, but not by these fluids when rendered resinous by age. It is more readily fusible than the others, and makes the best varnish. The West India copal is in flat pieces, seldom weighing more than three ounces, rarely containing insects, very hard, of a rough appearance, of a yellowish colour, and without smell or taste. It is much less readily dissolved by the oil of turpentine than the E. India variety, swells but does not dissolve in oil of rosemary, and is slightly soluble in absolute alcohol. A third kind, probably also American, is in convex or concave pieces, about a pound in weight, often containing insects and other impurities. In solubility it resembles the last mentioned variety, in fusibility is intermediate between it and the E. Indian, and is altogether inferior. (*Pharm. Journ. and Trans.*, Aug. 1850.) *Crude* and *scraped* copal are also known in the market—the former of a dull opaque appearance externally, the latter much clearer and more transparent, in consequence of being deprived of its outer coat. The process of *scraping* is said to consist in the removal of the exterior portion by means of an alkaline solution, which readily dissolves copal. This resin is used chiefly in the preparation of varnishes.

CORAL. A substance found at the bottom of the Mediterranean and other seas, formerly considered as a plant, but now universally admitted to belong to the animal kingdom. The *red coral* (*Corallium rubrum* of Lamarck, *Isis nobilis* of Linn.) is in the form of a small shrub, a foot or two in height, with a stem sometimes an inch or two in thickness, fixed to the rock by an expansion of the base, divided above into branches, and covered with a pulpy membrane, which is properly the living part, and which is removed when the coral is collected. The central portion is extremely hard, of various shades of red, susceptible of a brilliant polish, longitudinally striated, and formed of concentric layers, which are rendered obvious by calcination. Its chief constituent is carbonate of lime, which is coloured by oxide of iron, and united, as in similar calcareous products, with more or less animal matter. It was formerly highly esteemed as a remedy, but is in no respect superior to prepared oyster shell, or other form of carbonate of lime, derived from the animal kingdom. It was employed in fine powder, or in different preparations, such as troches, syrups, conserves, &c. At present it is valued chiefly as an ornament.

CORTEX CARYOPHYLLATA. *Cassia Caryophyllata. Clove Bark* These names have been given to a bark, brought from the West Indies, and derived from a tree belonging to the family of Myrtaceæ, supposed to be the *Myrtus acris* of Schwartz. It is usually in cylinders from one to two feet long by an inch in diameter, composed of numerous separate pieces rolled around one another, having a dark-brown colour, a pungent taste, and an odour similar to that of cloves. It is sometimes in fragments, of a similar colour, taste, and smell, but softer and lighter,and supposed to be derived from older branches. A similar bark is said to be derived from the *Myrtus caryophyllata* of Linn., which grows in Ceylon. The clove bark has aromatic properties not unlike those of the spice from which it derived its name; but it is much inferior, and is now never used in this country. Some authors have confounded with it a wholly different bark, produced in the Moluccas, and known by the Indian name of culilawan. (See *Culilawan.*)

CORYLUS ROSTRATA. *Beaked Hazel.* This is a small indigenous shrub, growing especially in mountainous districts. The nut is invested with a scaly involucre, projecting beyond it like a beak, and thickly covered with short spicula like those of Mucuna pruriens.

These spicula have been employed by Dr. Heubener, of Bethlehem, Pennsylvania, as an anthelmintic, and found to be efficacious. They operate in the same way as cowhage, and may be administered in the same manner and dose. (See a communication by the late Mr. Duhamel, in the *Am. Journ. of Pharm.*, xiv. 280.)

COTYLEDON UMBILICUS. *Navel-wort. Penny-wort.* This is a perennial, herbaceous, succulent plant, belonging to the class and order Decandria Pentagynia, and the natural family of Crapulaceæ. It is about six inches high, with fleshy, peltate, crenate leaves, and a flower-stem bearing, in the form of a spike, pale-yellow, bell-shaped, pendulous flowers, which appear in June and July. The plant is a native of England, where it grows upon old walls and rocks, and dry sandy banks. It was first brought before the profession as a remedy in epilepsy, by Mr. Thos. Salter, of Poole, who had found its expressed juice very efficient in that disease, and published the results of his observations in the *London Medical Gazette* for March, 1849 (*page* 367). In the following May, Dr. Joseph Bullar, of Southampton, communicated the results of his observations on the same subject to the *Prov. Med. and Surg. Journ.*, which were confirmatory of those of Mr. Salter. Since that period, other testimony has been advanced in favour of the remedy; among which is that of Dr. Graves, of Dublin, who considers it a valuable aid in the treatment of epilepsy, and states that it has long been known in Ireland as a popular remedy, not only in that disease, but in asthma. (*Dublin Quart. Journ. of Med. Sci.*, xiv. 264.) It is, however, proper to say, that Dr. Ranking, of Norwich, England, in a letter published in the *Lond. Med. Times and Gaz.* for April, 1854 (*page* 328), declares that, so far as his experience goes, he considers the medicine utterly worthless, having employed it perseveringly in more than thirty cases of epilepsy, without the smallest benefit in a single instance.

The medicine is said to have no other observable effect than that of a gentle tonic to the nervous system. The part used is the expressed juice, which should be obtained when the leaves are most succulent, before the appearance of the flowers. An extract, and a fluid extract have also been employed. The juice has been given in doses varying from a fluidrachm to a fluidounce twice or three times a day, and should be long persevered with. The dose of the fluid extract is stated at a fluidrachm, that of the dry extract at five grains, to be increased if necessary.

CRABS' CLAWS. *Chelæ Cancrorum.* These, in a prepared state, were formerly included in the Edinburgh Pharmacopœia, but were very properly omitted upon the last revision of that work. Supposing them identical with the crust of the lobster, they consist, in the 100 parts, of 60 parts of carbonate of lime, 14 of phosphate of lime, and 26 of animal matter. They are prepared by levigation and elutriation, so as to bring them to a fine powder. They were formerly used as an absorbent and antacid; but the animal matter in their composition confers on them no peculiar virtues. They are given in the same dose with prepared chalk.

CRABSTONES. *Lapilli Cancrorum. Crabs' Eyes.* These are concretions, found in the stomach, one on each side, of the European crawfish, at the time the animal is about to change its shell. They are most abundantly procured in the province of Astracan, in Asiatic Russia. The crawfish are bruised with wooden mallets, and laid up in heaps to putrefy. The animal remains are then washed away, and the stones picked out. They are inodorous, insipid bodies, somewhat hemispherical in shape, of a white or reddish colour, hard and stony consistence, and laminated texture. They are very variable in size, weighing from one to twelve grains each. They effervesce with acids, and, without dissolving, become converted, owing to the animal matter which they contain, into a soft transparent mass, retaining the original shape of the stone. By this character they are distinguished from counterfeit stones, which are sometimes fabricated of chalk, mixed with mucilaginous substances. They consist of carbonate and phosphate of lime, cemented together by animal matter. Crabstones have been used as an absorbent and antacid, given in the same dose with prepared chalk. They were prepared for exhibition by being levigated in the usual manner; but they are now no longer officinal, having been expunged from the Edinburgh Pharmacopœia.

CROCUS OF ANTIMONY. *Saffron of Antimony.* This compound is generated during the deflagration of equal weights of tersulphuret of antimony and nitrate of potassa. The nitric acid of the nitre is decomposed, nitrogen and nitric oxide being given off, and, by furnishing oxygen to part of the tersulphuret, converts its constituents into sulphuric acid and teroxide of antimony. The sulphuric acid combines with the potassa of the nitre, to form sulphate of potassa; while the teroxide unites or mixes with the undecomposed tersulphuret to constitute the crocus. The product of the deflagration is reduced to powder, washed to separate sulphate of potassa, and then fused. When crocus of antimony is intended to be employed for making tartar emetic, it should not be fused; because it requires for preparing this antimonial to be reduced to a very fine powder, and

the fused substance is pulverized with difficulty. Instead of fusing the deflagrated mass, it should be reduced to very fine powder, and washed with boiling water. In this state it more readily dissolves in the solution of cream of tartar.

Fused crocus is in masses of a liver-brown colour. As obtained without fusion, it is a saffron-brown insoluble powder, containing about two-fifths of its weight of teroxide, the remainder being tersulphuret. In the London Pharmacopœia of 1836, the unfused crocus was used for preparing tartar emetic; but in the edition of 1851 the crocus has been abandoned, and the subsulphate of antimony substituted for it.

CUCUMBER OINTMENT. An emollient ointment, prepared from the common cucumber (fruit of *Cucumis sativus*), has been considerably employed in irritated states of the skin. The following is the mode of preparing it recommended by Prof. Procter. Take of green cucumbers 7 pounds avoirdupois, pure lard 24 ounces, veal suet 15 ounces. Grate the washed cucumbers to a pulp, express, and strain the juice. Cut the suet into small pieces, heat it over a salt water bath till the fat is melted out from the membrane; then add the lard, and, when melted, strain through muslin into an earthen vessel capable of holding a gallon, and stir until thickening commences, when one-third of the juice is to be added, and the whole beaten with a spatula till the odour has been almost wholly extracted. The portion which separates is to be decanted, and the remaining two-thirds of the juice are to be consecutively incorporated and decanted in the same manner. The jar is then closely covered and placed in a water-bath, until the fatty matter entirely separates from the juice. The green coagulum floating on the surface is now removed, and the jar put in a cool place that the ointment may solidify. The crude ointment is then separated from the watery liquid on which it floats, melted and strained, and placed in glass jars, which must be kept closely sealed. A layer of rose water upon its surface will favour its preservation. A portion may be triturated with a little rose water until white and creamy, and put into a separate jar for present use. (*Am. Journ. of Pharm.*, xxv. 409.)

CUCURBITA CITRULLUS. *Watermelon.* The seeds of the watermelon are employed, to a considerable extent, as a domestic remedy in strangury and other affections of the urinary passages. They have the same properties with the seeds of the other Cucurbitaceæ, of which four different kinds were formerly officinal under the name of the *greater cold seeds*—viz., those of the *Cucurbita Pepo* or pumpkin, the *Cucurbita Lagenaria* or gourd, the *Cucumis Melo* or muskmelon, and the *Cucumis sativus* or cucumber. These, when bruised and rubbed up with water, form an emulsion which was formerly thought to possess considerable virtues, and was much used in catarrhal affections, disorders of the bowels and urinary passages, fever, &c.; but they have been superseded by other more agreeable demulcents. Watermelon seeds are also esteemed by some diuretic. They are given in infusion, made with one or two ounces of the bruised seeds to a pint of water, and taken *ad libitum*.

The seeds of the *Cucurbita Pepo*, or *pumpkin*, have recently obtained in this country considerable reputation in the treatment of *tape-worm*. This employment of them, however, is not new. In the *Dictionary of Materia Medica* by Mérat and De Lens (ii. 493), it is stated that Dr. Hoarau had reported that, in the Isle of France, the seeds of a small variety of pumpkin were used against the tape-worm, and with never-failing success. In the year 1820, M. Mongeny, a physician of Cuba, published the results of his experience with the flesh of the pumpkin in the same disease. He had discovered the remedy by accident, and found it uniformly successful. He gave to the patient, in the morning, fasting, about three ounces of the fresh pumpkin in the form of a paste, and followed it at the end of an hour by about two ounces of honey, which latter was twice repeated at intervals of an hour. MM. Brunet and Lamothe, of Bordeaux, verified the statements of M. Mongeny, as to the efficacy of the remedy in tænia, employing, however, a paste made from the seeds, in the quantity of about an ounce and a half, with as much sugar. (*Ann. de Thérap.* 1853, p. 301.)

In the *Boston Med. and Surg. Journ.* (October 8, 1851, *page* 201), is a communication from Mr. Richard Soule, recommending the seeds in very strong terms as a remedy in tænia; and his letter is preceded by some editorial observations, in which reference is made to the previous successful employment of the remedy by Dr. J. S. Jones, of Boston. Since that time various other notices of the efficacy of the seeds have appeared in the journals, and a very striking case was related to ourselves, on the best authority, in which they had proved immediately and completely successful after the vain employment of all other known remedies, through a course of several years. Mr. Soule gives the preference to the seeds from the West Indies. The dose of the seeds is about two ounces; which are to be taken in the morning fasting, and followed in an hour or two by a fluidounce of castor oil. The mode of administration is various. Sometimes the seeds, deprived of their outer covering, are beaten into a paste with sugar, and thus taken. In other in-

stances they are formed into an emulsion, by rubbing them up thoroughly with water, and a little sugar. At the suggestion of the late Dr. H. S. Patterson, of Philadelphia, the expressed oil of the seeds was used in a case by Mr. John C. Lyons, and with success. After fasting for 24 hours, the patient took, in the morning, f℥ss of the oil, which was followed in two hours by f℥ss more, and in two hours after the last dose by f℥i of castor oil, which brought away the worm. (*Med. Examiner*, N. S., ix. 629.)

CULILAWAN. *Cortex Culilaban.* An aromatic bark, produced by *Cinnamomum Culilawan* (*Laurus Culilawan*, Linn.), a tree of considerable size, growing in the Molucca islands, Cochin-china, and other parts of the East. It is usually in flat or slightly rolled pieces, several inches long, an inch or more in breadth, and one or two lines thick. Sometimes the bark is thinner and more quilled, bearing considerable resemblance to cinnamon. The epidermis is for the most part removed, but when present is of a light brownish-gray colour, soft to the touch, and somewhat spongy. The colour of the bark itself is a dull dark cinnamon-brown, the odour highly fragrant, the taste agreeably aromatic, and not unlike that of cloves. The active constituent is a volatile oil, which may be separated by distillation. Culilawan has the medical properties common to the aromatics, but is scarcely used at present.

CUNILA MARIANA. *American Dittany.* A small indigenous perennial herb, growing on dry, shady hills, from New England to Georgia, and flowering in June and July. The whole herb has a warm pungent taste, and a fragrant odour, dependent on an essential oil. Its medical properties are those of a gently stimulant aromatic, analogous to the mints, pennyroyal, &c. In warm infusion, it is popularly employed to excite perspiration in colds and slight fevers, to promote suppressed menstruation, to relieve flatulent colic, and for various other purposes to which the aromatic herbs are thought applicable.

CUTTLE-FISH BONE. *Os Sepiæ.* This is a calcareous body, situated underneath the skin, in the back of the *Sepia officinalis*, or *cuttle-fish*, which inhabits the seas of Europe, especially the Mediterranean, in the waters of which the bone is not unfrequently found floating. It is oblong-oval, from five to ten inches long, and from one and a half to three inches broad, somewhat convex on both sides, with thin edges, of a rather firm consistence upon the upper surface, very friable beneath, and composed of numerous layers, loosely connected, so as to give to the mass a porous consistence. It is lighter than water, of a white colour, a feeble odour of sea plants, and a saline taste. It contains, according to John, from 80 to 85 per cent. of carbonate of lime, besides animal matter, a little common salt, and traces of magnesia. Reduced by levigation and elutriation to a fine powder, it may be given as an antacid like chalk or oyster-shell. It is sometimes used as an ingredient of tooth-powders. Small pieces of it are often put into bird-cages, that the birds may rub their bills against them; and the powder is employed for polishing. Another product of the cuttle-fish is a blackish-brown liquor, secreted by a small gland into an oval pouch, communicating externally near the rectum by a long excretory duct, through which the animal is said to have the power of ejecting it at will. This, when taken from the fish, is dried, and used in the preparation of the water colour called *sepia*.

CYANURET OF ZINC. *Zinci Cyanuretum.* This cyanuret is precipitated as a white insoluble powder, by adding cautiously, until it ceases to produce a precipitate, a recently filtered solution of cyanuret of potassium, obtained from the impure black cyanuret, to a solution of sulphate of zinc. It is used in Germany as a substitute for hydrocyanic acid, and is said to possess anthelmintic properties. It has been employed in epilepsy, chorea, and neuralgia, in several painful affections of the stomach, and in the colics attendant on difficult menstruation. The dose is a quarter of a grain, gradually increased to a grain and a half, given in mixture. It is included in the officinal list of the French Codex.

CYNANCHUM VINCETOXICUM. R. Brown. *Asclepias Vincetoxicum.* Linn. *White Swallow-wort. Vincetoxicum.* A perennial herbaceous European plant, the root of which was formerly esteemed a counterpoison, and hence gave origin to the officinal name. It has a bitterish acrid taste, and, when fresh, a disagreeable odour which is diminished by drying. Taken internally, especially in the recent state, it excites vomiting, and is capable in large quantities, of producing dangerous if not fatal inflammation of the stomach. Its former reputation as an alexipharmic was without foundation. It is said to be useful in cutaneous diseases, scrofula, &c., but is little employed. The leaves of the plant also are emetic. Feneulle found in the root a peculiar principle analogous to emetin.

CYNARA SCOLYMUS. *Garden Artichoke.* This is a perennial plant, indigenous in the South of Europe, and cultivated in our gardens as a culinary vegetable. The flowers, constituting what are commonly called the *heads*, are the part used. The receptacle and the lower portion of the fleshy leaflets of the calyx are eaten, and the other parts rejected. When young, the heads are cut up raw and eaten as salad; when older, they are boiled, and

dressed variously. The flowers are said to curdle milk, and the plant to yield a good yellow dye. The leaves and their expressed juice are very bitter, and have been thought to be actively diuretic. They have long had some reputation in the treatment of dropsies. Dr. Badely, of Chelmsford, England, recommends a tincture and extract prepared from the leaves, in rheumatic, gouty, and neuralgic affections. He gives a drachm of the tincture, with five grains of the extract, three times a day, with or without other remedies as circumstances seem to require. The leaves should be fresh, and the preparations made from them quickly used. (*Lond. Lancet*, 1843, p. 556.)

CYNOGLOSSUM OFFICINALE. *Hound's Tongue.* A biennial plant, common both in Europe and this country, and named from the shape of its leaves. The leaves and root have been employed, but the latter has been generally preferred. The fresh plant has a disagreeable narcotic odour resembling that of mice, which is dissipated by drying. The taste is nauseous, bitterish, and mucilaginous. Different opinions as to its powers have been entertained, some considering it nearly inert, others as a dangerous poison. Hound's tongue has been used as a demulcent and sedative in coughs, catarrh, spitting of blood, dysentery, and diarrhœa: and has been applied externally in burns, ulcers, scrofulous tumours, and goitre. The *pilulæ de cynoglosso*, which are officinal in some parts of Europe, though they contain the root of hound's tongue, owe their properties chiefly to opium.

CYPRIPEDIUM PARVIFLORUM. *Ladies' Slipper. Moccasin Plant.* Several species of Cypripedium inhabit the woods in different parts of the United States, some of them with very beautiful flowers. The root is the part used. Dr. R. P. Stevens, of Ceres, Pennsylvania, says of them, that he has found the *C. spectabile* and *C. acaule*, especially when growing in dark swamps, to be possessed of narcotic properties, and to be less safe than the *C. parviflorum*, which is a gentle stimulant with a tendency to the nervous system, and is considered by him quite equal to valerian. He has employed it advantageously in hysteria, and in the pains of the joints following scarlet fever. (*N. Y. Journ. of Med.*, iv. 359.) Dr. E. Ives considers the *C. pubescens*, *spectabile*, and *humile* as identical in their effects, but the *pubescens* as the most powerful. He has employed them all in a variety of nervous diseases, and known them to cure epilepsy. The complaints specially mentioned by him are hypochondriasis, neuralgia, and morbid sensitiveness of the nervous system generally, and especially of the eye. He gave fifteen grains three times a day. (*Trans. of Am. Med. Assoc.*, iii. 312.)

DIANTHUS CARYOPHYLLUS. *Clove Pink.* The *clove pink* or *carnation* is too well known to require minute description. It is a perennial, herbaceous plant, belonging to the family of Caryophyllaceæ, and characterized as a species by its branching stem, its solitary flowers, the short ovate scales of its calyx, its very broad beardless petals, and its linear, subulate, channeled, glaucous leaves. Indigenous in Italy, it is everywhere cultivated in gardens for the beauty of its flowers, of which numerous varieties have been produced by horticulturists. Those are selected for medicinal use which have the deepest red colour, and the most aromatic odour. The petals should not be collected till the flower is fully blown, and should be employed in the recent state. They have a fragrant odour, said to resemble that of the clove. Their taste is sweetish, slightly bitter, and somewhat astringent. Both water and alcohol extract their sensible properties, and they yield a fragrant essential oil by distillation. In Europe they are employed to impart colour and flavour to a *syrup*, which serves as a vehicle for other less pleasant medicines. According to the direction of the former Edinburgh Pharmacopœia, this was prepared by macerating one part of the flowers, without their claws, with four parts of boiling water for twelve hours, then filtering, and adding seven parts of sugar.

DIAPHORETIC ANTIMONY. *Antimonium Diaphoreticum. Potassæ Biantimonias.* This compound is directed in the French Codex, to be formed by deflagrating in a red-hot crucible, and keeping red-hot for half an hour, a mixture of pure antimony with twice its weight of nitrate of potassa, both being in fine powder. The product is washed with water and dried, and forms the *washed diaphoretic antimony*. As thus prepared, M. Oscar Figuier has shown that it contains, besides antimonic acid, both teroxide of antimony and antimonious acid; the nitre not being in sufficient quantity completely to peroxidize the antimony. When, however, the antimony is deflagrated with three times its weight of nitre, and the matter is kept at a red heat for an hour and a half, the whole of the antimony is converted into antimonic acid; and, when the product is thoroughly exhausted by boiling water, the solution obtained contains a large quantity of neutral antimoniate of potassa, and the insoluble residue is impure biantimoniate. M. Figuier rejects this residue, which forms the diaphoretic antimony of the ordinary process, and obtains the preparation from the solution of the neutral antimoniate, by passing through it a stream of carbonic acid gas, which removes one eq. of potassa from two of the antimoniate, and throws down the biantimoniate in the form of a white powder. By this process, he obtained a quantity of

the preparation equal to three-fourths of the weight of the materials employed. Diaphoretic antimony is a perfectly white powder. When properly prepared, as by the process of M. Figuier, it consists of two eqs. of antimonic acid, one of potassa, and six of water. The dose is two or three drachms. On account of its weak and variable nature, it has been very properly laid aside in practice.

DICTAMUS ALBUS. *White Fraxinella. Bastard Dittany.* This is a perennial European plant, the root of which is bitter and aromatic, and has been used as an anthelmintic, emmenagogue, and stomachic tonic, though at present little employed in Europe, and not at all in this country. Störck gave it in intermittents, worms, amenorrhœa, hysteria, epilepsy, and other nervous diseases. The bark of the root is the most active part. The dose is from a scruple to a drachm.

DIPPEL'S ANIMAL OIL. *Oleum Cornu Cervi.* This oil is obtained during the distillation of bones, in the processes for obtaining ammoniacal products on a large scale. The portion which first comes over is pale-yellow; but, in the progress of the distillation, it becomes gradually deeper coloured and thicker, and at last black and viscid. It is purified and rendered colourless by redistillation, a pyrogenous resin being left behind. Thus rectified it is a colourless liquid, very limpid and volatile, with a penetrating extremely fetid odour, and burning taste. By repeating the distillation till a dark residuum is no longer left in the retort, it may be obtained free from fetor, and of an agreeable, aromatic odour; and in this mode it is said to have been prepared by Dippel. Four or five distillations are necessary. (*Am. Journ. of Pharm.*, ix. 244.) The oil is soon altered by the action of air and light, becoming thick, yellow, brown, and finally black. It has an alkaline reaction, and probably contains the various principles which have been discovered by Reichenbach in the products of the distillation of organic substances.

This oil was originally obtained from hartshorn, and was a product of the decomposition of the gelatinous tissue, the horn containing no fat. When obtained from bones, it is a product of the same tissue; as these are boiled with a large quantity of water, and dried, before they are submitted to destructive distillation. The oily product of this distillation, after rectification, forms the *bone-oil* of commerce. Bone-oil has a dark-brown almost black colour, with a greenish shade. It is perfectly opaque in the mass, but brown when viewed by transmitted light in a thin layer. Its sp. gr. is about 0·970. Its smell is peculiarly disagreeable and somewhat ammoniacal. A piece of fir-wood, moistened with muriatic acid, and held over the mouth of a vessel containing it, acquires, a dark reddish-purple colour, characteristic of pyrrol. It contains several organic bases, such as *petinin*, *picolin*, *&c.*, which have been examined by Dr. Thomas Anderson, of Scotland. (See his paper on the Products of the Distillation of Animal Substances, in the *Philos. Mag.*, 3d series, xxx. 174.)

Animal oil was formerly much used in medicine; but its repulsive odour and taste, as it is ordinarily prepared, have caused it to be almost entirely laid aside. It is given in the dose of a few drops, mixed with water, and acts as a stimulant and antispasmodic. Its presence in the spirit and salt of hartshorn gives to these preparations medicinal properties different from those of the pure spirit and carbonate of ammonia.

DIRCA PALUSTRIS. *Leather Wood.* An indigenous shrub, usually very small, but sometimes attaining the height of five or six feet, growing in boggy woods, and other low wet places, in almost all parts of the United States. The berries, which are small, oval, and of an orange colour, are said to be narcotic and poisonous. The bark has attracted most attention. It is extremely tough, and of very difficult pulverization. In the fresh state it has a peculiar rather nauseous odour, and an unpleasant acrid taste, and when chewed excites a flow of saliva. It yields its acrimony completely to alcohol, but imperfectly to water even by decoction. In the dose of six or eight grains, the fresh bark produces violent vomiting, preceded by a sense of heat in the stomach, and often followed by purging. Applied to the skin it excites redness, and ultimately vesicates; but its epispastic operation is very slow. It appears to be analogous in its properties to mezereon, to which it is botanically allied.

DRAGON'S BLOOD. *Sanguis Draconis.* This is a resinous substance obtained from the fruit of several species of *Calamus*, especially *C. Rotang* and *C. Draco*, small palms, growing in the Molucca Islands and other parts of the East Indies. On the surface of the fruit, when ripe, is an exudation, which is separated by rubbing, or shaking in a bag, or by exposure to the vapour of boiling water, or finally by decoction. The finest resin is procured by the two former methods. It comes in two forms; sometimes in small *oval masses*, of a size varying from that of a hazelnut to that of a walnut, covered with the leaves of the plant, and connected together in a row like beads in a necklace; sometimes in *cylindrical sticks* eighteen inches long and from a quarter to half an inch in diameter, thickly covered with palm leaves, and bound round with slender strips of cane. In both these forms, it is

of a dark reddish-brown colour, opaque, and readily pulverizable, affording a fine scarlet powder. It sometimes comes also in the form of a reddish powder, and in small irregular fragments or tears. An inferior kind, said to be obtained by boiling the fruit in water, is in *flat circular cakes*, two or three inches in diameter and half an inch thick. This also yields a fine red powder. A fourth variety, much inferior even to the last mentioned, is in *large disks*, from six to twelve inches in diameter, by an inch in thickness, mixed with various impurities, as pieces of the shell, stem, &c., and supposed to be derived from the fruit by decoction with expression. A substance known by the name of Dragon's blood is derived by exudation from the trunk of the *Dracæna Draco*, a large tree inhabiting the Canary Islands and the East Indies, and another from the *Pterocarpus Draco*, a tree of the West Indies and South America, by incision into the bark. These last, however, are little known in commerce. According to Lieut. Wellstead, much dragon's blood is obtained, in the island of Socotra, by spontaneous exudation from a large tree, growing at a considerable elevation on the mountains.

Dragon's blood is inodorous and tasteless, insoluble in water, but soluble in alcohol, ether, and the volatile and fixed oils, with which it forms red solutions. According to Herberger, it consists of 90·7 parts of a red resin which he calls *draconin*, 2·0 of fixed oil, 3·0 of benzoic acid, 1·6 of oxalate of lime, and 3·7 of phosphate of lime. It was formerly used in medicine as an astringent, but is nearly or quite inert, and is now never given internally. It is sometimes used to impart colour to plasters, but is valued chiefly as an ingredient of paints and varnishes.

DUTCH PINK. A yellow or brownish-yellow paint, consisting of clay, or a mixture of clay and chalk, or carbonate of lime in the form of whiting, coloured by a decoction of woad, French berries, or birch leaves, with alum.

EMERY. A very hard mineral, the powder of which is capable of wearing down all other substances except the diamond. As found in commerce, it is said to be derived chiefly from the island of Naxos in the Grecian Archipelago, but, according to Landerer, it has been found also in Asia Minor, and the Morea. It is pulverized by grinding it in a steel mill; and the powder is kept in the shops of different degrees of fineness. It is used for polishing metals and hard stones.

EPIGÆA REPENS. *Trailing Arbutus. Ground Laurel. May-flower.* This is a small trailing plant, with woody stems from six to eighteen inches long, entire, cordate-ovate leaves, and small very fragrant flowers, which appear early in the spring. It is found in the woods, and affects the sides of hills with a northern exposure. Dr. Darlington states that the plant has been supposed to be injurious to cattle, when eaten by them. (*Flora Cestrica*, p. 259.) Dr. Eli Ives, of New Haven, Connecticut, has furnished us with the following account of its virtues and uses, founded on his own observation. "The Epigæa repens has been freely used for some years in diseases of the urinary organs, and of the pelvic viscera generally, particularly of irritated action, in those cases in which the uva ursi and buchu are indicated. The leaves and stems are prepared in the same manner, and administered in the same dose as the uva ursi. The Epigæa has given relief in some cases where the uva ursi and buchu have failed. May 4th, 1849."

EUONYMUS ATROPURPUREUS. *Burning Bush. Spindletree. Wahoo.* Some years since a bark was introduced into notice in this city, as a remedy in dropsy, under the name of wahoo, by Mr. Geo. W. Carpenter, who had obtained a knowledge of its virtues in the Western States. On a journey to the North West in the year 1845, one of the authors had the opportunity of examining the plant from which the bark was derived, and found it to be *Euonymus atropurpureus;* but it is probable that *E. Americanus* has identical properties. They are shrubs or small trees belonging to the Linnæan class and order Pentandria Monogynia, and to the natural family of Celastraceæ of Lindley; and in the autumn present a striking appearance from the rich red colour of their capsules, which has obtained for them the name of burning bush. They grow throughout the United States. Euonymus Europæus has probably similar properties. According to Grundner, who experimented with the fruit of the European species, this was found to have no other effect than that of a diuretic. (*Pharm. Cent. Blatt*, A. D. 1847, p. 873.) Dr. Griffith says that the seeds of this and other species are purgative and emetic. (*Med. Bot.*, p. 220.) An oil expressed from these seeds is used in Europe for the destruction of vermin in the hair, and sometimes also as an application to old sores. (*Pharm. Cent. Blatt*, Sept. 1851, p. 641.) Mr. C. A. Santos, in a dissertation upon the American species, published in the *American Journal of Pharmacy* (xx. 80), speaks of the bark as tonic, hydragogue, cathartic, diuretic, and antiperiodic. Dr. Twyman, of Westport, Missouri, informed the author that he had found it as a cathartic rather to resemble rhubarb, than to possess hydragogue properties, and thought he had obtained useful effects from it as an alterative to the hepatic function. Similar information was obtained from other sources. On the whole, the character of its

action must be considered as somewhat uncertain; and it might well form an object of further examination. As a diuretic in dropsy it may be given in the form of decoction or infusion, made in the proportion of an ounce to a pint of water, in the dose of a wine-glassful several times a day. The name of *wahoo* (pronounced *wawhoo*), by which the plant is known in the North West, was given to it by the Indians. The same name has also been applied to the *Ulmus alata* of the Southern States, and has thus led to mistakes.

EUPHRASIA OFFICINALIS. *Eyebright.* A small annual plant, common to Europe and the United States, without odour, and of a bitterish, astringent taste. It was formerly used in various complaints, and among the rest in disorders of the eyes, in which it was thought to be very efficacious, and in the treatment of which it is still popular in some countries. The probability is that it is nearly inert.

FERROCYANURET OF ZINC. *Zinci Ferrocyanuretum.* This compound is formed by double decomposition between hot solutions of ferrocyanuret of potassium (ferroprussiate of potassa) and sulphate of zinc. It is thrown down as a white powder. It has similar medical properties to those of the cyanuret, and is used in the same diseases. The dose is from one to four grains, given in pill.

FRAXINUS EXCELSIOR. *Common European Ash.* It has been stated, in the first part of this work, that, in the South of Europe, this tree yields manna by incisions in its trunk. In this place, however, it is noticed only in reference to its bark and leaves. The bark is bitter and astringent, and, before the introduction of cinchona into use, was employed in the treatment of intermittent fever; but has since fallen into neglect. Keller believed that he had found in the bark a peculiar crystallizable organic alkali, which Buchner denominated *fraxinin;* but Rochleder and Schwarz have since shown that the crystals formed along with the bitter substance obtained by the process of Keller, were nothing but mannite. (*Pharm. Cent. Blatt*, May, 1853, p. 312.) The *leaves* have been at different times recommended as an antidote to the poison of serpents, and as a remedy in scrofula. Within a few years they have been introduced into use in Germany in the treatment of gout and rheumatism, in which they have acquired considerable reputation. Drs. Pouget and Peyraud, of France, have spoken in the highest terms of their efficacy in these diseases; and, upon the authority of the former, it is stated that they have been used for forty years by the peasants of Auvergne as a specific in gout. M. Garot has shown that they contain 16 per cent. of *malate of lime*, to which it is thought their anti-arthritic virtues may be ascribed. (*Journ. de Pharm.*, 3e *sér.*, xxiv. 311.) By some authors the leaves are said to be purgative, which is, however, contradicted by Drs. Pouget and Peyraud. An ounce may be infused in a pint of boiling water, and taken three times during the day. (See *Am. Journ. of Med. Sci.*, N. S., xxv. 492.)

FRENCH CHALK. A variety of indurated talc. It is compact, unctuous to the touch, of a greenish colour, glossy, somewhat translucent, soft and easily scratched, and leaves a silvery line when drawn over paper. It is used chiefly for marking cloth, &c., and for extracting grease spots.

FRUIT ESSENCES, ARTIFICIAL. Several of the compound ethers have been found to possess the odour and flavour of certain fruits, a property which has led to their employment as flavouring materials for confectionery and desserts, under the name of fruit essences. The simple ethers, present in these compounds, so far as they have become of commercial importance, are common ether, or oxide of ethyle, which should be called ethylic ether, and oxide of amyle or amylic ether. Each of these ethers possesses basic properties, and has its alcohol; common or ethylic ether corresponding to common or ethylic alcohol, and amylic ether to amylic alcohol or fusel oil. These alcohols are hydrated oxides of ethyle and amyle respectively. (See *Alcohol Amylicum*, p. 851, and *Alcohol*, p. 852.)

Butyrate of Ethylic Ether. Butyric Ether. ($C_4H_5O,C_8H_7O_3$.) This ether is readily prepared by mixing 100 parts of butyric acid with 100 of alcohol, and 50 of concentrated sulphuric acid, and agitating the mixture for a short time. The ether forms a layer on the surface, and may be purified by washing it with water, and subjecting it to the action of chloride of calcium. Butyric ether is sparingly soluble in water, but very soluble in alcohol, and boils at 230°. It is said to be much used to communicate a pine-apple flavour to rum. Dissolved in 8 or 10 parts of alcohol it forms the *pine-apple essence.* From 20 to 25 drops of this essence, added to a pound of sugar containing a little citric acid, imparts to the mixture a strong taste of pine-apple. *Butyric acid* is formed during what is called the butyric fermentation, which usually consumes two or three months before it is completed, and which is preceded by the lactic fermentation. To prepare it a solution of grape sugar is mixed with half its weight of chalk, and with about one-tenth of its weight of cheese to act as a ferment, and the whole is kept at the temperature of 90°. The sugar is first transformed into a viscous substance, and afterwards into lactic acid, which is gradually

converted into butyric acid, with the disengagement of hydrogen and carbonic acid. At the end of the fermentation, the liquid contains principally a mixture of butyrate and lactate of lime, from which the butyric acid may be obtained by precipitating the lime as a carbonate by carbonate of soda, and decomposing the resulting butyrate of soda with sulphuric acid. Butyric acid is a colourless liquid, having a very disagreeable odour and a rancid taste. It dissolves in all proportions in water and alcohol, boils at 327° F., and has the density of 0·963. It is a hydrated acid, having the formula $C_8H_7O_3.HO$.

Pelargonate of Ethylic Ether. Pelargonic Ether. Œnanthic Ether. ($C_4H_5O,C_{18}H_{17}O_3$). A preliminary step in forming this ether is to prepare the *pelargonic acid*. This is most conveniently obtained, according to Dr. R. Wagner, by the action of nitric acid on oil of rue. Treat the oil with double its weight of very dilute nitric acid, and heat the mixture until it begins to boil. Two layers are formed in the liquid; the upper one being brownish, and the lower consisting of the products of the oxidation of the oil, with the excess of nitric acid. The lower layer, having been separated, is freed from the greater part of the nitric acid by evaporation in a chloride of zinc bath, and then filtered. The filtrate is a solution of pelargonic acid, and may be converted into pelargonic ether by a prolonged digestion, at a gentle heat, with alcohol. The ether, as thus prepared, has the agreeable odour of quince, and, when dissolved in alcohol in due proportion, forms the *quince essence*. (See *Am. Journ. of Pharm.*, July, 1853, p. 320.) *Pure* pelargonic ether (œnanthic ether) is a colourless liquid, having an agreeable vinous odour, and a taste, at first slight, but afterwards acrid. Its sp. gr. is 0·87, and boiling point, when constant, 433° F. Pelargonic acid, so called from its having been first obtained from *Pelargonium roseum*, or rose geranium, is a hydrated acid, and has the formula $C_{18}H_{17}O_3.HO$. Delffs's analysis of œnanthic acid gives it the same composition, and, accordingly, he considers the two acids as undoubtedly identical. (*Chem. Gaz.*, April 15, 1852, p. 144.) The formula given for œnanthic acid at *page* 753 must, therefore, be abandoned.

Acetate of Amylic Ether. ($C_{10}H_{11}O,C_4H_3O_3$). This is prepared by distilling a mixture of one part of amylic alcohol (fusel oil), two of acetate of potassa, and one of concentrated sulphuric acid. The distilled liquid is purified from free acid, by washing with a weak alkaline solution, and from water, by distillation from chloride of calcium. It is a colourless, limpid liquid, lighter than water, boiling at 272° F., insoluble in water, but soluble in alcohol. It possesses the odour, in a remarkable degree, of the Jargonelle pear, and is manufactured on a large scale for flavouring syrups and confectionery. An alcoholic solution of this ether forms the *Jargonelle pear essence*. Fifteen parts of acetate of amylic ether, with half a part of acetic ether, dissolved in 100 parts of alcohol, form what may be called the *bergamot pear essence*, which, when employed to flavour sugar acidulated with a little citric acid, imparts the odour of the bergamot pear, and a fruity, refreshing taste. Acetate of amylic ether, mixed with butyric ether, forms another fruity compound, which recalls the odour of the banana, and forms, in alcoholic solution, the *banana essence*.

Valerianate of Amylic Ether. ($C_{10}H_{11}O,C_{10}H_9O_3$). This is made by carefully mixing four parts of pure amylic alcohol (fusel oil) with four of sulphuric acid, and adding the mixture, when cold, to five parts of valerianic acid. The whole is warmed for a few minutes in a water-bath, and then mixed with a little water, which causes the ether to separate. Lastly, it is purified by washing it with water and a weak solution of carbonate of soda. An alcoholic solution of this ether, in the proportion of one part to six or eight of alcohol, forms a flavouring liquid under the name of *apple essence*. For the mode of obtaining valerianic acid, see *Valerianate of Soda*, p. 1188.

It is thus perceived that the bases of the fruit essences are certain ethereal compounds of organic acids with the oxides of ethyle and amyle. Besides the essences here described, there are found in commerce the strawberry, raspberry, apricot, green gage, mulberry, and black currant essences, all of which may be viewed as various mixtures of the ethers of the ethyle and amyle series, modified by the addition of pure nitrous ether, vanilla, volatile oils, &c., to bring about a resemblance to the fruit, the odour and taste of which it is the object to imitate. In making these essences, it is important that the materials should be pure, especially the fusel oil and alcohol. The alcohol, used as a solvent, should be rectified and deodorized.

These fruit essences are extensively employed for flavouring ices, jellies, lozenges, and drops, and for making fruit syrups and effervescent beverages. They are manufactured on a large scale by Messrs. Mander, Weaver, & Co., of Wolverhampton, England, and sold by their agents, Messrs. Phelps, Fowler, & Co., of New York. The more useful ones are also prepared by Messrs. Powers & Weightman, manufacturing chemists, of Philadelphia.

FUCUS VESICULOSUS. *Sea-wrack. Bladder-wrock.* This was omitted as an officinal in the edition of the Dublin Pharmacopœia of 1850. It belongs to *Cryptogamia Algæ* in the sexual system, and to the natural order Algaceæ. The following is the generic character.

"MALE. *Vesicles* smooth, hollow, with villose hairs within, interwoven. FEMALE. *Vesicles* smooth, filled with jelly, sprinkled with immersed grains, prominent at tip. *Seeds* solitary." This sea-weed is perennial, with the frond or leaf flat, smooth and glossy, from one to four feet high, from half an inch to an inch and a half broad, furnished with a midrib throughout its length, dichotomous, entire upon the margin, and of a dark olive-green colour. Small spherical vesicles, filled with air, are immersed in the frond near the midrib. The fruit consists of roundish, compressed receptacles, at the ends of the branches, filled with a clear tasteless mucus. The plant grows upon the shores of Europe and of this continent, attaching itself to the rocks by its expanded woody root. On the coast of Scotland and of France, it is much used in the preparation of kelp. It is also employed as a manure, and is mixed with the fodder of cattle. It has a peculiar odour, and a nauseous saline taste. Several chemists have undertaken its analysis, but the results are not satisfactory. It contains much soda in saline combination, and iodine, according to Gaultier de Claubry, in the state of iodide of potassium. These ingredients remain in its ashes, and in the charcoal resulting from its exposure to heat in close vessels. This charcoal, which is sometimes called *Æthiops vegetabilis* or *vegetable ethiops*, has long had the reputation of a deobstruent, and been given in goitre and scrofulous swellings. Its virtues were formerly ascribed chiefly to carbonate of soda, in which it abounds; but, since the discovery of the medical properties of iodine, this has been considered as its most active ingredient. The mucus contained in the vesicles was applied externally, with advantage, by Dr. Russel, as a resolvent in scrofulous tumours.

Other species of Fucus are in all probability possessed of similar properties. Many of them contain a gelatinous matter, and a sweet principle analogous to mannite; and some are used as food in times of scarcity. Large quantities of a sea weed, named in the East *agar-agar*, are gathered on the rocky coasts of the East India Islands, and sent to China, where it is valued for making jellies, and a size for stiffening silks. The *Ceylon moss* is a delicate fucus (*Gigartina lichenoides*), growing on the coast of Ceylon, where it is gathered by the natives. It abounds in starch and vegetable jelly, which render it applicable to the same purposes as the carrageen or Irish moss. (*Pharm. Journ. and Trans.*, xiii. 355.) *F. Helminthocorton* (*Gigartina Helminthocorton* of Greville) has some reputation in Europe as an anthelmintic, and is said also to be febrifuge. It is one of the ingredients in that mixture of marine plants which is sold in Europe under the name of *Corsican moss* or *helminthocorton*. This is used in decoction, from four to six drachms being boiled in a pint of water, and a wineglassful given three times a day.

FULIGOKALI. This preparation, proposed by M. Deschamps, is formed by boiling for an hour, 20 parts of caustic potassa, and 100 of shining soot, in powder, in 2 parts or a sufficient quantity of water. The solution, when cold, is diluted, filtered, and evaporated to dryness. Fuligokali is in the form of a black powder, or of scales, very soluble in water, and having an empyreumatic odour and mild alkaline taste. It is used in the same affections as *anthrakokali*. The dose is two or three grains, repeated several times a day. An ointment, containing from sixteen to thirty-two grains to the ounce of lard, was found by Dr. Gibert, of Paris, to be detersive, resolvent, and gently stimulant. (See a paper by the late A. Duhamel, in the *Am. Journ. of Pharm.*, xiv. 284.)

FUMARIA OFFICINALIS. *Fumitory.* A small annual European plant, naturalized in this country, growing in cultivated grounds, and flowering from May to August. It was formerly considerably employed as a medicine, and is still used in Europe. The leaves are the officinal part. They are inodorous, have a bitter saline taste, and are very succulent, yielding by expression a juice which has the sensible and medicinal properties of the plant. An extract prepared by evaporating the expressed juice, or a decoction of the leaves, throws out upon its surface a copious saline efflorescence. The plant, indeed, abounds in saline substances, and to these, in connexion with its bitter extractive, its medical virtues are to be ascribed. It is gently tonic, in large doses is said to be laxative and diuretic, and is thought, moreover, to have an alterative action. Both in ancient and modern times it has been esteemed a valuable remedy in visceral obstructions, particularly those of the liver, in scorbutic affections, and in various troublesome eruptive diseases. Cullen speaks favourably of its influence in these last complaints. He gave the expressed juice in the dose of two ounces twice a day. Others have prescribed it in much larger quantities. The leaves either fresh or dried may be used in decoction, without precise limitation as regards the dose. The inspissated juice and an extract of the dried leaves have also been employed.

FUSTIC. A yellow dye-wood, obtained from *Morus tinctoria* (*Broussonetia tinctoria*, Kunth), a tree growing in the West Indies and South America. It is not used in medicine or pharmacy. According to Bancroft, two different woods bear in England the name of fustic, one the product of the tree just mentioned, distinguished as *old fustic*, probably

from the greater magnitude of the billets in which it is imported: the other derived from the *Rhus Cotinus* or *Venice sumach*, and called *young fustic*. The wood of M. tinctoria owes its colouring properties to two principles which have been isolated by R. Wagner, one which he has denominated *morin*, and the other bearing some resemblance to tannic acid, which he calls *moritannic acid*. (See *Chem. Gaz.*, ix. 1, 21, and 241.)

GALANGAL. *Galanga.* Two varieties are described by authors, the *galanga major* and *galanga minor*, or *large* and *small galangal*. They are considered by some as the roots of different plants: but there is reason to believe that they are both derived from *Maranta Galanga* of Linn. (*Alpina Galanga* of Willd.), and that they differ in consequence of the different stages of growth at which they are collected. They are brought from the East Indies. The *larger variety* is cylindrical, three or four inches long, as thick as the thumb or thicker, often forked, reddish-brown externally, slightly striated longitudinally, marked with whitish circular rings, orange-brown internally, rather hard and fibrous, difficultly pulverizable, of an agreeable aromatic odour, and a pungent, hot, spicy, permanent taste. The *small galangal* resembles the preceding in shape, but is smaller, not exceeding the little finger in thickness, of a darker colour, and of a stronger taste and smell. According to Morin, galangal contains a volatile oil, an acrid resin, extractive, gum, bassorin, and liguin. A. Vogel, jun., found also starch and fixed oil. (*Pharm. Cent. Blatt*, 1844, p. 158.) R. Brandes is said to have found a peculiar crystallizable substance called *kempferid*. (*Annal. der Pharm.*, xxxii. 311.) The active principles are the volatile oil and acrid resin. Its medical effects are those of a stimulant aromatic. It was known to the ancient Greeks and Arabians, and formerly entered into numerous compound preparations. At present it is seldom employed. Its dose is from fifteen to thirty grains in substance, and twice as much in infusion.

GALEGA OFFICINALIS. *Goat's Rue.* A perennial herb, growing in the South of Europe, and sometimes cultivated in gardens. It is without smell unless bruised, when it emits a disagreeable odour. Its taste is unpleasantly bitter and somewhat rough, and when chewed, it stains the saliva yellowish-brown. In former times it was much employed as a remedy in malignant fevers, the plague, the bites of serpents, worms, &c.; but it has fallen into merited neglect. The roots of *Galega Virginiana*, a native of the United States, are said to be diaphoretic and powerfully anthelmintic. They are given in decoction.

GALIUM APARINE. *Cleavers. Goose-grass.* This is an annual, succulent plant, common to Europe and the United States, growing in cultivated grounds, and along fences and hedges. It is inodorous, and has a bitterish, herbaceous, somewhat acrid taste. Analyzed by Schwartz, it was found to contain, besides chlorophylle, starch, and other principles common to all plants, three distinct acids, viz.: a variety of tannic acid, which he names *galitannic acid*, citric acid, and a peculiar acid previously discovered by Schwartz and Rochleder, and named *rubichloric acid*. (*Pharm. Journ. and Trans.*, xii. 190.) The expressed juice is said to be aperient, diuretic, and anti-scorbutic; and has been used in dropsy, congestion of the spleen, scrofula, and scorbutic eruptions. In the last complaint it has been thought peculiarly useful. Three ounces of the juice may be taken twice a day. Dr. Winn, of Truro, Cornwall, has recently called the attention of the profession to this medicine. Several persons in his neighbourhood had been cured of lepra by a decoction of the plant: and he had himself employed it with great advantage not only in this but other cutaneous diseases. At first he gave it in the form of decoction made by boiling a handful of the recent herb in a quart of water for twenty minutes, of which a tumblerful was given three times a day; but he now prefers the inspissated juice, in the form of a fluid extract, of which ʒj represents Oss of the decoction. (*London Med. Times and Gaz.*, Feb. 1854, page 144.) The fresh herb, in the form of ointment or decoction, has been applied externally to scrofulous swellings with supposed advantage.

GALIUM VERUM. *Yellow Ladies' Bed-straw. Cheese rennet.* This species of Galium is perennial, and a native of Europe. The flowers, which are yellow, have a peculiar, agreeable odour, and have been given in nervous affections, with a view to their supposed antispasmodic powers. The herb is inodorous, but has an astringent, acidulous, bitterish taste. The property of coagulating milk was formerly ascribed to it, but is certainly not constant, as the experiment has been frequently tried without success. The bruised plant is sometimes used to colour cheese yellow, being introduced into the milk before coagulation. It is also used for dyeing yellow. The roots of this and of most other species dye red; and the plant, eaten by animals, colours the bones like madder. This plant was analyzed by Schwartz, and found to contain the same principles as *G. Aparine*, mentioned above. It was formerly highly esteemed as a remedy in epilepsy and hysteria, and was applied externally in cutaneous eruptions. It may be employed in the form either of the recently expressed juice, or of a decoction prepared from the fresh plant. Its medical properties, however, are feeble.

Of the American species, the *G. tinctorium* is closely allied in properties to G. verum. It is said to be useful in cutaneous diseases; and the root is employed by the Indians for staining their feathers and other ornaments red.

GELSEMINUM SEMPERVIRENS. Juss. *Gelseminum Nitidum.* Michaux. *Bignonia Sempervirens.* Willd. *Yellow Jasmine. Carolina Jasmine.* This is one of the most beautiful climbing plants of our Southern States, ascending lofty trees, and forming festoons from one tree to another, and in its flowering season, in the early spring, scenting the atmosphere with its delicious odour. It belongs to the Linnæan class and order Pentandria Digynia, and the natural family of Apocynaceæ. The stem is twining, smooth, and shining; the leaves perennial, opposite, shortly petiolate, lanceolate, entire, dark-green above, and paler beneath; the flowers in axillary clusters, large, of a deep-yellow colour and fragrant, with a very small, five-leaved calyx, and a funnel-shaped corolla, having a spreading, five-lobed, nearly equal border. The fruit is a flat, compressed capsule, divisible into two parts, two-celled, and furnished with flat seeds, which adhere to the margins of the valves. The root is the part employed. It is said to have a slight narcotic odour and an agreeably bitter taste, and yields its virtues to water, and readily to diluted alcohol. From the accounts given of its effects, it appears to be a cerebro-nervous sedative, without nauseating or purgative properties, but sometimes causing diaphoresis, especially in febrile diseases. In moderate doses it produces agreeable sensations of languor, with muscular relaxation, so that the patient finds some difficulty in moving the eyelids, and keeping the jaws closed. More largely taken it occasions dizziness, dimness of vision, dilated pupil, general muscular debility, and universal prostration; but after a short time these symptoms pass off leaving no unpleasant effects. It is no doubt capable of causing death in over-doses, and must therefore be used cautiously.

The discovery of its medical virtues was accidental. A planter of Mississippi, labouring under an obstinate bilious fever, directed his servant to get a particular root from the garden, and prepare a tea from it. The tea was prepared accordingly, and drank by the invalid, who was soon afterwards affected with great prostration, and especially muscular debility, so that he could not raise a limb, but without stupor. These effects gradually passed off, and with them the fever. The servant had made a mistake in the root, and dug that of the Gelseminum, instead of the one intended. The planter, having made this discovery, employed the root afterwards with success upon his own plantation and in the neighbourhood. The remedy passed into the hands of irregular practitioners, and was employed by the "eclectic physicians" before its virtues came to the knowledge of the profession. Attention was called to it by a paper of Professor Procter in the *Am. Journ. of Pharm.* for October, 1852 (*page* 307), who derived most of his information from the "*Eclectic Dispensatory,*" and a paper by F. D. Hill, in the "*Eclectic Medical Journal*" of Cincinnati. Communications have since been published in reference to it in the *Southern Journ. of Med. and Phys. Sciences,* for January, 1853 (*page* 40) by Dr W. S. Jenkins, of Castilian Spring, Tenn.; in the *Stethoscope* of Nov. 1853 (*page* 636) by Dr. H. M. Nash, of Norfolk, Va.; and in the *Iowa Med. Journ.* by Dr. Bachelor (see *Charleston Med. Journ. and Rev.*, March, 1854, *page* 243). From these sources most of the statements in this article were drawn. The diseases in which the medicine has been prescribed are intermittent, remittent, and typhoid fevers, inflammation of the lungs and pleura, rheumatism, neuralgia, chorea, and epilepsy. The preparation usually employed is a tincture made by macerating for two weeks the fresh bark of the root, well bruised, in diluted alcohol, or some form of ardent spirit, and then expressing, and filtering. It has a dark-red colour, and the bitterness of the root, and is probably saturated. The dose is from ten to fifty drops, every hour or two; but is of course somewhat indefinite, as there is no precise formula for the tincture. Dr. Jenkins gives from half a teaspoonful to three times the quantity.

GENISTA TINCTORIA. *Dyers' Broom. Dyers' Weed. Green Weed.* A low shrub, growing wild in Europe, and sometimes cultivated in this country in gardens. The flowering tops of the plant are employed to dye yellow, whence its name was derived. Both these and the seeds have been used in medicine. They are said to be purgative and even emetic, especially the seeds, which were formerly given as a cathartic in the dose of a drachm and a half. By some authors they are said to be diuretic, and to be useful in dropsy. The plant has been long used as a preventive of hydrophobia by the peasants of Podolia, the Ukraine, and other provinces of Russia. They employ it in the form of strong decoction, both internally and locally, in connexion with *Rhus coriaria,* and persevere with it for six weeks. The trials made with it in other parts of Europe have failed.

GERANIUM ROBERTIANUM. *Herb Robert.* This species of Geranium grows wild both in Europe and the United States, but is rare in this country; and Pursh states that the American plant is destitute of the heavy smell by which the European is so well known, though the two agree in all other respects. The herb has a disagreeable, bitterish,

astringent taste, and imparts its virtues to boiling water. It has been used internally in intermittent fever, consumption, hemorrhages, nephritic complaints, jaundice, &c., has been employed as a gargle in affections of the throat, and has been applied externally as a resolvent to swollen breasts and other tumours.

GLASS OF ANTIMONY. *Vitrum Antimonii.* This is prepared from the tersulphuret of antimony by a partial roasting and subsequent fusion. The tersulphuret is reduced to coarse powder, and strewed upon a shallow, unglazed earthen vessel, and heated gently and slowly, being continually stirred to prevent it from running into lumps. White vapours of sulphurous acid arise; and when these cease, the heat is increased a little to reproduce them. The roasting is continued in this manner until, at a red heat, no more vapours are given off. The matter is then melted in a crucible with an intense heat, and kept in a state of fusion until it assumes the appearance of melted glass, when it is poured out on a heated brass plate. In this process, part of the sulphur of the tersulphuret is driven off by the roasting; while the portion of antimony which loses its sulphur becomes teroxidized. The roasted matter, accordingly, consists of teroxide of antimony and undecomposed tersulphuret; and these, by uniting during the fusion, form the glass. Glass of antimony is in thin irregular pieces, exhibiting a vitreous fracture, and having a metallic steel-gray lustre. When well prepared it is transparent, and, upon being held between the eye and the light, appears of a rich orange-red, or garnet colour; but if of inferior quality it is black and opaque. It is hard and brittle, and rings when struck with a hard substance. It is insoluble in water, but soluble in acids and in cream of tartar, with the exception of a few red flocculi. Its essential constituents are the teroxide and tersulphuret, united in variable proportions. When of good quality it consists of about eight parts of teroxide to one of tersulphuret. It usually contains about five per cent. of silica, and three of sesquioxide of iron, which are derived from the crucible, and to the former of which the vitrification of the product is owing. When good it is dissolved, with the exception of a few red flocculi, in strong muriatic acid. An excess of silica is known by the acid leaving a gelatinous residuum, and the iron may be detected by ferrocyanuret of potassium, and its amount judged of by the bulk of the precipitate and the depth of its blue colour. Sometimes *glass of lead* is sold for glass of antimony, a fraud easily detected by the difference between the two substances in specific gravity; the glass of lead having a density of nearly seven, while that of glass of antimony is not quite five.

Medical Properties, &c. Glass of antimony is an active antimonial; but, owing to its variable composition and uncertain operation, is at present very seldom used. When the levigated powder is mixed with one-eighth of its weight of melted yellow wax, and the mixture roasted over a slow fire, with constant stirring until it ceases to exhale vapours, a coal-like pulverizable mass is formed, which is the *cerated glass of antimony*, a preparation formerly included in the Edinburgh Pharmacopœia.

GLECHOMA HEDERACEA. *Nepeta Glechoma. Ground-ivy.* A small perennial herb, indigenous in Europe and the United States, and growing in shady grassy places, as in orchards and along fences and hedges. It belongs to the family of labiate plants, and shares their general properties. The herb was formerly officinal, and still enjoys some credit as a domestic remedy. It has a peculiar disagreeable odour, and a bitterish, rough, somewhat aromatic taste, and imparts its properties to boiling water. From the statements of authors, it appears to be gently stimulant and tonic, with, perhaps, a peculiar direction to the lungs and kidneys. It has also been considered aperient. The complaints in which it has been most used are chronic affections of the pulmonary and urinary organs; and at one time it had considerable reputation as a remedy in consumption. It has also been employed as a vulnerary and errhine. The usual form in which it was administered was that of infusion, of which a quantity was given for a dose containing the virtues of half a drachm or a drachm of the herb.

GLUE. An impure form of gelatin, obtained from various animal substances by boiling them in water, straining the solution, and evaporating it till upon cooling it assumes the consistence of jelly. The soft mass which results is then divided into thin slices, which are dried in the open air. Glue, when of good quality, is hard and brittle, of a brown colour, and equally transparent throughout. It softens and swells very much in cold water, without dissolving; but is readily dissolved by hot water. It is employed chiefly for cementing pieces of wood together, being too impure for the purposes of a test, or for internal use.

Capsules of Gelatin. Glue has within a few years been applied to an important practical purpose in pharmacy. Certain medicines are so offensive to the taste, and consequently so apt to sicken the stomach, that it is highly desirable to administer them in such a way as to prevent their contact with the tongue and palate. This object is fully accomplished, so far as regards many disagreeable liquid medicines, by the use of the

capsules of gelatin, invented by M. Dublanc, of Paris. These are prepared from the purest glue in the following manner. Small pouches made of fine skin, of an oval form, are attached by a waxed thread to the smaller extremity of a hollow elongated metallic cone, which is bent towards its point, and has its base closed by a cover, which is screwed so as to make the instrument air-tight. Into this conical tube sufficient mercury is poured to fill the pouch, which, thus distended, is dipped into a concentrated sweetened solution of glue, and afterwards exposed to heat in a vertical position, so as to dry the layer of gelatin which it has received. In the same manner a second coating may be given, and the process again repeated till a sufficient thickness has been obtained. The cone being then reversed, the mercury flows out of the pouch, which collapses, and allows the capsule of gelatin to be removed. Into this the medicine may now be introduced, care being taken to avoid any contact with the outer surface of the capsule. The opening is next to be closed by means of a thin lamina of gelatin previously softened by steam; and a solution of the same substance should be applied to the edges by means of a camel's hair pencil. Another mode of preparing the capsules is as follows. Take a cylinder of iron or hard wood, four lines in diameter and a few inches long, and smoothly rounded at one end. Dip half an inch of this end first into a saturated warm alcoholic solution of soap, and afterwards, when the soap has concreted upon the surface, into a concentrated hot solution of gelatin, and repeat the latter immersion once or oftener, if it be desired to have a firm capsule. When the glue has concreted, remove the capsule. A top for it may be made in the same way, and, after the body has been filled with the liquid to be given, is to be applied and secured by rubbing a camel's hair pencil moistened with hot water over the line of junction. (*Med. Exam.*, N. S., i. 441.) M. Mothès considers the following plan of preparing the capsules the most convenient. He has a number of assorted "copper olives" prepared, covers their surface with a layer of something to prevent oxidation, immerses them in a sweetened and aromatized concentrated solution of gelatin, then places them vertically on boards to cool, and before complete desiccation removes the capsules, places them on sieves, and dries them by a stove-heat. (*Journ. de Pharm. et de Chim.*, xvii. 204.) For an account of another process, invented and described by Mr. Alfred Guillou, of Philadelphia, the reader is referred to the *Am. Journ. of Pharm.* (ix. 20). The capsules may be made of such a capacity as to contain from ten to fifteen grains of copaiba.

GNAPHALIUM MARGARITACEUM. *Cudweed. Life-everlasting.* An indigenous herbaceous perennial, growing in fields and woods, and flowering in August. The herb of this and of *G. polycephalum*, or *sweet-scented life-everlasting*, is sometimes used in the form of tea by the country people, in diseases of the chest and of the bowels, and in hemorrhagic affections, and externally, in the way of fomentation, in bruises, languid tumours, and other local complaints; but it probably possesses little medical virtue. Shoepf says that it is anodyne. In Europe, different species of Gnaphalium are also occasionally employed for similar purposes.

GOLD. *Aurum.* The preparations of this metal were introduced to the notice of physicians by Dr. Chrestien, of Montpellier, in 1810. They are employed both internally, and by frictions on the tongue and gums. The principal affections in which they have been recommended are secondary syphilis, syphilitic ulcerations, scrofula, and inveterate eruptions, particularly those of a leprous character. The chief preparations which have been employed, up to the present time, are metallic gold in a finely divided state, the oxide (teroxide or auric acid), the chloride (terchloride), the iodide, the double chloride of gold and sodium, the chloroaurate of ammonia (a compound of terchloride of gold and muriate of ammonia), and the cyanuret (tercyanuret) of gold. *Gold in powder* may be obtained by rubbing up gold-leaf with 10 or 12 times its weight of sulphate of potassa until brilliant particles are no longer visible, and then washing away the sulphate with boiling water. The *oxide* may be procured by treating the nitromuriatic solution of gold with an excess of magnesia, and washing the precipitate, first with water, and afterwards with dilute nitric acid. This process being tedious, M. L. Figuier prefers to obtain the oxide by precipitating a cold solution of chloride of gold, rendered strongly alkaline by caustic potassa, with a solution of chloride of barium. The precipitate, consisting of aurate of baryta, is then treated with dilute nitric acid, which dissolves the baryta and leaves the oxide of gold pure. Ten parts of gold, thus treated, produced 11¾ parts of oxide; while the same quantity of metal by the magnesia process, only yielded 9 parts. (*Journ. de Pharm.*, Dec. 1847.) The *chloride* is obtained by dissolving pure gold in three times its weight of nitromuriatic acid, with the aid of a moderate heat. The solution is evaporated by a gentle heat nearly to dryness, being at the same time stirred with a glass rod. It is in the form of a crystalline mass of a deep-red colour. Its solution has a fine yellow tint. Being deliquescent, it requires to be kept in ground-stoppered bottles. The *iodide* may be made by precipitating a solution of terchloride of gold by one of iodide of

potassium, and washing the precipitate with alcohol to remove the excess of iodine. It is of a greenish-yellow colour, and, when heated in a porcelain crucible, is resolved into iodine vapours and a residue of pure gold. *Chloride of gold and sodium* is prepared by dissolving four parts of gold into nitromuriatic acid, evaporating the solution to dryness, and dissolving the dry mass in eight times its weight of distilled water. To this solution one part of pure decrepitated common salt is added, previously dissolved in four parts of water. The mixed solution is then evaporated to dryness, being in the mean time constantly stirred with a glass rod. This salt is of a golden-yellow colour, and, when crystallized, is in the form of long prismatic crystals, unalterable in the air. The *chloroaurate of ammonia* is formed by dissolving one part of the terchloride of gold and two parts of muriate of ammonia in distilled water, assisted by a few drops of nitromuriatic acid, and evaporating the solution to dryness by a gentle heat. The *cyanuret* is best obtained, according to M Oscar Figuier, as follows. Prepare the chloride of gold as neutral as possible by repeated solutions and crystallizations; and to the solution of this salt add, very cautiously, avoiding any excess, a solution of *pure* cyanuret of potassium, so long as any precipitate falls. (See *Potassii Cyanuretum.*) The precipitate, consisting of cyanuret of gold, is to be washed with pure water and dried in the dark. Gold in powder, and the oxide, chloride, iodide, sodio-chloride, and cyanuret are officinal in the French Codex.

The preparations of gold are decidedly poisonous, though in different degrees. The chloride is most virulent, and, according to Dr. Chrestien, is even more active than corrosive sublimate. In an over dose, it produces pain, inflammation, and even ulceration of the stomach and bowels, and otherwise acts as a corrosive poison. The general effects of these preparations, in moderate doses, is to produce increased fulness and frequency of the pulse, and to augment the urine and insensible perspiration, without interfering with the appetite or the regular action of the bowels; but if the dose be pushed too far, general irritation is apt to be produced, inflammation seizes upon some organ, according to the predisposition of the individual, and fever is developed.

Gold in powder, the oxide, chloride, and *iodide* are not as much used as the double chloride of gold and sodium. The oxide may be given in the form of pill, in the dose of a tenth of a grain, in scrofula and lymphatic swellings, beginning with one pill daily, and afterwards gradually increasing to seven or eight in 24 hours. The chloride has been used with advantage as a caustic, in lupus, and syphilitic tubercles and ulcers, by M. Chavannes. The iodide may be given in the same cases with the other preparations. The dose is from the fifteenth to the tenth of a grain.

Chloride of gold and sodium is the preparation of gold most commonly employed. It may be given in lozenges, each containing the twelfth of a grain, by mixing intimately five grains of the salt with an ounce of powdered sugar, and making the whole with mucilage of tragacanth into a proper mass, to be divided into sixty lozenges. Pills, containing the same dose, may be formed by dissolving ten grains of the dried salt in a drachm of distilled water, and forming the solution into a pilular mass with a mixture of four drachms of potato starch and one drachm of gum Arabic, to be divided into one hundred and twenty pills. (*Journ. de Pharm.*, xx. 648.) For frictions on the gums and tongue, Chrestien recommends the following formula:—Crystallized chloride of gold and sodium, one grain; powdered orris root, deprived of its soluble parts by alcohol and water, and dried, two grains. Mix. At first the fifteenth part of this powder is used daily by frictions; afterwards the fourteenth, the thirteenth, &c., until, increasing gradually, the tenth or eighth part is employed. The use of four grains of the salt in this way is said commonly to cure bad cases of recent syphilis; such, for example, as are characterized by the co-existence of chancres, warts, and buboes. In preparing this powder, lycopodium may be substituted for the orris.

Chloroaurate of ammonia has been recommended by Bouchardat in amenorrhœa and dysmenorrhœa in debilitated subjects, in the dose of about the tenth of a grain. A grain may be dissolved in five teaspoonfuls of alcohol and five of water, and a teaspoonful given morning and evening, mixed with sweetened water.

Cyanuret of gold is employed, like the chloride of gold and sodium, mixed with inert powders, by friction, and in the form of pill. The fifteenth of a grain may be rubbed into the gums daily for fifteen days, next the fourteenth of a grain for fourteen days, and so on, increasing until the dose amounts to the ninth or eighth of a grain. The dose for internal exhibition is the eighteenth of a grain, gradually increased to the eighth. Cyanuret of gold has been found useful in the treatment of syphilis and scrofula by M. Pourché, and is said to be less exciting than the double chloride, when used in those diseases. (*Journ. de Pharm.*, xx. 599 and 649.)

The different medicinal compounds of gold should not be prepared in pill, powder, or otherwise, until they are wanted for use; as they are liable to undergo decomposition when kept. They should be carefully secluded from the light.

GRATIOLA OFFICINALIS. *Hedge Hyssop.* This is a perennial herb, indigenous in the South of Europe, where it flourishes in meadows and other moist grounds. The whole herb is used. It is nearly inodorous, but has a bitter nauseous taste. Both water and alcohol extract its active properties. It is a drastic cathartic and emetic, possessing also diuretic properties, and is employed on the continent of Europe in dropsy, jaundice, worms, chronic hepatic affections, scrofula, and various other complaints. With us it is almost unknown as a remedy. The dose of the powdered herb is from fifteen to thirty grains; of the infusion made in the proportion of half an ounce to the pint of boiling water, half a fluidounce.

GUACO. This name is given in Central and South America, and the West Indies, to various plants having supposed alexipharmic properties, and belonging to the genera *Mikania* and *Aristolochia;* but it is to the different species of the former genus that the appellative properly belongs, and especially to the *Mikania Guaco*, described by Humboldt and Bonpland. (*Pl. Æq.*, ii. 84.) The genus Mikania belongs to the Linnæan class and order *Syngenesia Æqualis*, and to the natural order *Asteraceæ*. The plants are closely allied to the Eupatoria. For their generic character, see *Lindley's Flora Medica* (*page* 451), and *Griffith's Medical Botany* (*page* 392). *Mikania Guaco* is described as having twining stems, with round, sulcate, and hairy branches; ovate, subacuminate, remotely dentate leaves, somewhat narrowed at the base, rough above, and hairy beneath; and flowers in opposite, axillary corymbs. The plant is a native of intertropical America, and has been introduced into the W. India Islands from the continent. The leaves are the part used. In the recent state they have a bitter taste, and a strong disagreeable odour; but their sensible properties and medical virtues are impaired by drying.

This and other plants have long been employed by the natives as a preventive and cure of the bites of poisonous serpents. This application of them was first made known by Mutis; and his account was confirmed by Humboldt and Bonpland. The medicine has also been employed as a febrifuge and anthelmintic, and a few years since attracted considerable attention for its supposed prophylactic and remedial powers in epidemic cholera and chronic dysentery. It has, moreover, been recommended in chronic rheumatism, both internally and locally, and as a direct application in bites of insects, bruises and sprains, and atonic deafness. The probability, however, is that, like eupatorium, it has simply the virtues of a mild tonic, and gentle stimulant to the secretions. It is best employed in the recent state. The natives, when employing it as a counter-poison, apply the bruised leaves and expressed juice to the bite, and at the same time drink of the infusion. The preparations recommended for internal use are chiefly an infusion and tincture, the former made in the proportion of an ounce of the leaves to a pint of boiling water, the latter of about a pound to the gallon of proof spirit. The dose may be about the same as analogous preparations of eupatorium. (See *Lond. Med. Times and Gaz.*, Dec. 1852, p. 651, and *Journ. de Pharm.*, 3*e sér.*, xx. 357.)

GUANO. *Bird-manure.* This is a valuable manure, consisting of the decomposed excrement of countless aquatic birds, which has accumulated for ages on certain barren and uninhabited islets of the western coast of South America, and in other localities throughout the world. The best comes from Peru, and will be here described. It is a coarse dry powder of a brown colour. Exposed to the air it absorbs moisture, and becomes somewhat sticky. Its smell is offensive, and somewhat ammoniacal. With the powder are intermingled friable lumps, which exhibit in their inside whitish specks, and which, when exposed to the air, fall to powder, exhaling an ammoniacal smell. It is soluble in great part in water, and the solution formed contains chiefly oxalate of ammonia. When exposed to heat it blackens, burns with a slight flame, exhales the smell of ammonia, and leaves a whitish ash, varying in amount from 27 to 35 per cent. The guanos of commerce vary very much in composition, from the best Peruvian to the inferior sorts, which have scarcely any value as fertilizers. A good specimen of guano, analyzed by Fownes, consisted of about two-thirds oxalate of ammonia, and one-third earthy and alkaline phosphates, &c. The source of the oxalate of ammonia is undoubtedly the uric acid, originally in the excrement, and which is often found undecomposed in the guano. The value of guano as a fertilizer, depends chiefly upon the proportion of the nitrogenous ingredients; the phosphates being of secondary importance. Unger obtained from Peruvian guano, a peculiar substance, analogous to xanthic oxide, and called *guanine.* It forms crystallizable salts with acids, and has the formula $N_5C_{10}H_5O_2$.

In Colombia, S. A., guano has been used with benefit, internally and externally, as a remedy in the different forms of lepra. The late Prof. Horner, of Philadelphia, used it as a cataplasm, mixed with an equal quantity of potter's clay, in chronic inflammation of the knee-joint. In this proportion it blistered the surface; and cataplasms were afterwards used, containing one-third and one-fourth of guano. (*Med. Exam.*, Feb. 1852, p. 69.) Prof.

Horner attributed the revulsive effect of the guano to urate of ammonia; but the best authorities state that oxalate of ammonia is the characteristic salt of this substance.

GUN COTTON. *Pyroxylin.* This substance, discovered by Schönbein, of Bâle, in Switzerland, is conveniently prepared by the following process, given by Mr. Thomas Taylor, of London. Mix, in a glass vessel, 1½ fluidounces of nitric acid (sp. gr. 1·45) with an equal bulk of sulphuric acid, and, when the mixture has cooled, pour it upon 100 grains of fine cotton, contained in a Wedgwood mortar, and, with a glass rod, imbue the cotton as quickly as possible with the acids. As soon as the cotton is completely saturated, pour off the superabundant liquid, and, with the aid of the pestle, quickly press out as much of it from the cotton as possible. Then throw the cotton into a basin of water, wash it until it has not the slightest acid taste, and dry it with a gentle heat. Gun cotton may be made with strong nitric acid alone: but, as this acid is not always of full strength, it is better to mix with it sulphuric acid, which acts by strengthening the nitric acid, from its affinity for water. It is also prepared by immersing the cotton in a mixture of nitre and sulphuric acid.

Properties, &c. Gun cotton has the appearance of ordinary cotton, but is harsh to the touch. It is perfectly insoluble in water, and nearly so in strong alcohol; but dissolves in large quantity in acetic ether. As ordinarily prepared for commercial purposes, it is insoluble in ether, but, when carefully and *freshly* prepared, it dissolves in that menstruum, forming a powerfully adhesive liquid. (See *Collodium.*) According to Dr. J. H. Gladstone, of England, it is subject to spontaneous decomposition, if kept for some time. The same fact has been observed by Mr. James Beatson, of New York, and Prof. Procter, of Philadelphia. The specimen, observed by Prof. Procter to undergo decomposition, had not been well washed. The change is shown by the bottle, in which the gun cotton is kept becoming full of nitrous acid vapour; and the substance is so far altered that it is no longer explosive, or soluble in ether. According to M. Béchamp, of Strasburg, the product is soluble in ether, if the cotton be immersed in a mixture of nitre and sulphuric acid, while still hot from their reaction; but not soluble, if the cotton be added to the mixture when cold. By treating gun cotton with protochloride of iron, M. Béchamp caused the disengagement of nitrous oxide gas, and gave the filaments a coating of oxide of iron, which was readily dissolved off by muriatic acid. After this treatment the gun cotton was restored to its original state of cotton. (*Chem. Gaz.*, Jan. 1, 1854, p. 11.) When kindled gun cotton flashes off like gunpowder, burning without residue. Its inflaming point is at the temp. of 370°. Dr. Marx makes its inflaming point lower. It has been tried as a substitute for gunpowder in firearms; but, from its strong bursting power, it has not been found to answer for this purpose. It appears, however, to be well adapted to rock blasting. Its composition has not been satisfactorily determined. While Mr. T. Ransome, of Manchester, makes its composition correspond with that of lignin (cotton), in which two eqs. of hydrogen are replaced by two of nitric acid ($C_{12}H_{10}O_{10}-H_2+2NO_5=$ gun cotton $N_2C_{12}H_8O_{20}$); Mr. Walter Crum, of Glasgow, views it as the same substance, in which three eqs. of water are replaced by three of nitric acid ($C_{12}H_{10}O_{10}-3HO+3NO_5 = N_3C_{12}H_7O_{22}$). M. Pelouze gives a different formula.

GUTTA PERCHA. This valuable product of the East Indies was first brought into notice by Dr. Wm. Montgomerie, a British army surgeon, who became acquainted with its singular properties in the year 1842 at Singapore, and in the following year sent specimens of it to Europe. It is the product of a large tree growing in the southern extremity of the Malayan Peninsula, the island of Singapore, Borneo, and probably many other islands in the neighbourhood. This tree belongs to the Linnæan class and order Decandria Monogynia, natural family Sapotaceæ, and genus Isonandra of Dr. Wight, and has received the name of *Isonandra gutta.* It is of considerable magnitude, with a trunk commonly three feet, and sometimes as much as six feet in diameter, having numerous ascending branches, which are crowded with leaves at their extremities. The flowers are small and white; the leaves petiolate, oblong, four or five inches long by two in breadth, bright green above and brownish beneath. Dr. Montgomerie states that the natives procure the gutta percha by the very wasteful mode of cutting down the tree, stripping off the bark, and then collecting the milky juice, which is put into convenient recipients, and coagulates on exposure to the air. Twenty or thirty pounds are thus collected from each tree; but the probability is that the product would be much greater if obtained by tapping the tree, and thus preserving it for future use. Large quantities of gutta percha are now imported into Europe and this country. As found in commerce it is generally impure, containing fragments of vegetable matter and earth. From these it may be freed by kneading in hot water, or by melting it with oil of turpentine, straining, and evaporating.

Gutta percha is of a dull white or whitish colour, of a feeble odour, tasteless, at ordinary temperatures hard, almost horny, somewhat flexible in thin pieces, having an unctuous

feel under the fingers, and very tenacious. Its sp. gr. is 0·9791. (*Soubeiran.*) At about 120° F., it becomes softer and more flexible, but is still elastic, resisting, and tenacious. At 150° or 160°, it is soft, very plastic, and capable of being welded and moulded into any form. It is thus softened whether by means of hot water or by dry heat. On cooling it reassumes its former state, and retains any form which may have been given to it. In the softened state it is readily cut with a knife, though with some difficulty when cold. Exposed to a heat of 330° it loses a portion of water, and on hardening becomes translucent and gray; but it recovers its original characters if immersed in water. Subjected to igneous distillation it yields volatile products, resembling closely the volatile oil obtained from caoutchouc by the same process. Heated in an open vessel, it melts, foams up, and takes fire, burning with a brilliant flame and smoke. A portion thus melted retains the state of a viscid fluid on cooling. Gutta percha is a non-conductor of electricity. It is insoluble in water, alcohol, alkaline solutions, and the weak acids. Ether and the volatile oils soften it in the cold, and imperfectly dissolve it with the aid of heat. Oil of turpentine dissolves it perfectly, forming a clear colourless solution, which yields it unchanged by evaporation. It is also dissolved by bisulphuret of carbon, chloroform, and benzole. According to Soubeiran, it contains, besides pure gutta percha, small portions of a vegetable acid, casein, and two resins, one soluble in ether and oil of turpentine, the other in alcohol. (*Journ. de Pharm.*, 3e *sér.*, xi. 22.) Freed from these impurities, it has an ultimate composition closely analogous if not identical with that of caoutchouc. For a particular account of the distinctive properties of pure gutta percha, and the two resins mixed with it, the reader is referred to an article by M. Payen, in the *Journ. de Pharm.* (3e *sér.*, xxii. 183), also in the *Chem. Gaz.* (x. 353.) M. Arppe considers gutta percha as a mixture of six different resins, which may have been formed from a carbo-hydrogen $C_{10}H_8$. (See *Chem. Gaz.*, ix. 471.)

This singular substance has been applied to many useful and ornamental purposes. Its plasticity when moderately heated, and great firmness and tenacity at ordinary temperatures, and its insolubility in water and alcohol, are the properties to which it chiefly owes its value. By immersing it in hot water, it is made susceptible of being formed into any desirable shape; so that utensils of various kinds, metallic and other ornamental impressions, casts, sheets, bands, cords, sticks, tubs, &c., applicable to numerous purposes in the arts, may be made from it with great facility. To give it greater pliability, it is sometimes mixed with the tar resulting from the igneous decomposition of caoutchouc, or with its own tar and lampblack. It may be vulcanized in the same manner as caoutchouc, and undergoes a similar change of properties. (See *Caoutchouc.*)

In the dissolved state it may be employed as a varnish, impervious to moisture. It has been introduced into surgery, in order to preserve limbs and joints in fixed positions; and has been used beneficially in clubfoot, fractures, and diseases of the joints. It is employed for these purposes in the shape of bands, two or three inches broad and about a line thick, which, being softened in water, are applied in this state, and, when they harden, form a firm case for the limb. Holes should be made through the bands, for the escape of the vapour from the surface. It is also used for the formation of catheters and other tubes, splints, stethoscopes, bougies, specula, pessaries, and various other instruments, useful in surgery. Vogel recommends the solution in bisulphuret of carbon as an application to the skin in incised wounds. The liquid speedily evaporates, producing a refrigerant effect; while the gutta percha hardens, and holds the edges of the wound firmly together. According to Mr. Acton, the best substance for protecting the surface from the contact of poisons, contagions, &c., is prepared by dissolving with a gentle heat a drachm of gutta percha in an ounce of benzole, and ten grains of caoutchouc in the same quantity of the same menstruum, and mixing the solutions. It may be applied by a brush, and a delicate film is left by the evaporation of the liquid. A saturated solution in chloroform is highly recommended in various chronic affections of the skin by Dr. Graves, of Dublin. It is applied by means of a camel's hair pencil, and forms, on the evaporation of the solvent, a thin elastic covering, which completely excludes the air, and acts like an artificial cuticle to the part. The crusts or scales should be previously removed by poultices or alkaline solutions. The affections in which it has been found most efficacious, are the dry scaly and tubercular diseases of the skin, especially psoriasis. It has been used also to render the variolous eruption abortive. (*Dub. Quart. Journ. of Med. Sci.*, xiv., 1.)

HAMAMELIS VIRGINICA. *Witch-hazel.* An indigenous shrub, from five to fifteen feet high, growing in almost all sections of the United States, usually on hills or in stony places, and frequently on the banks of streams. It is remarkable for the late appearance of its yellow flowers, which expand in September or October, and continue till the weather becomes very cold in winter. The fruit, which is a nut-like capsule not unlike the hazelnut, ripens in the following autumn, and is often mingled on the same plant with the new

blossoms. The bark has a bitter, astringent, somewhat sweetish and pungent taste. It probably first attracted notice as a remedy of the Indians, who are said to have used it as a sedative and discutient in painful tumours, and other cases of external inflammation. It is used in the shape of poultice, or as a wash in the form of decoction, in hemorrhoidal affections and ophthalmia. The leaves are said to possess similar properties, and, in the state of infusion, to be given internally in bowel complaints and hemorrhages. Dr. James Fountain, of Peekskill, N. Y., speaks in strong terms of the efficacy of the bark in hemorrhage of the lungs and hæmatemesis, and also highly recommends, as one of the best applications in external piles, an ointment prepared from lard and a decoction of equal parts of this bark, white-oak bark, and that of the apple-tree. He believes the witch-hazel to possess anodyne properties. (*N. Y. Journ. of Med.*, x. 208.) Dr. N. S. Davis agrees with Dr. Fountain in his estimate of this remedy, which he has employed usefully in incipient phthisis. He gives it in decoction, made with an ounce of the bark to a pint of water, of which the dose is a wineglassful every three, six, or eight hours. (*Transact. of Am. Med. Assoc.*, i. 350.) The seeds are black and shining externally, white, oily, and farinaceous within, and edible like the hazel-nut.

HEDERA HELIX. *Ivy.* This well-known evergreen creeper is a native of Europe. The fresh *leaves* have a balsamic odour, especially when rubbed, and a bitterish, harsh, unpleasant taste. They are used for dressing issues, and, in the form of decoction, have been recommended in sanious ulcers and cutaneous eruptions, particularly tetter and the itch. Dried and powdered, they have been employed in the atrophy of children, and in complaints of the lungs, in the dose of a scruple or more. The *berries*, which have an acidulous, resinous, somewhat pungent taste, are said to be purgative and even emetic. MM. Vandamme and Chevallier discovered in ivy seeds a peculiar alkaline principle, which they called *hederin* (*hederia*). It is very bitter, and appears to be closely allied to quinia in febrifuge properties. It is obtained by treating the seeds with hydrate of lime, dissolving the precipitated alkali in boiling alcohol, and evaporating the alcoholic solution. (*Am. Journ. of Pharm.*, xiii. 172.) Prof. Posselt has discovered two acids in the seeds, one of which has their taste in a high degree, and was named by him *hederic acid*, the other he did not obtain quite pure. (See *Chem. Gaz.*, March 1, 1849, p. 93.) From the trunks of old ivy plants, growing in the South of Europe and the North of Africa, a resinous substance exudes through incisions in the bark, which has been employed in medicine under the name of *ivy gum*. It is in pieces of various sizes, of dark yellowish-brown colour sometimes inclining to orange, more or less transparent, sometimes of a deep ruby-red colour internally, of a vitreous fracture, pulverizable, yielding a lively orange-yellow powder, of a peculiar not disagreeable odour when heated or inflamed, and of a bitterish resinous taste. Its chief constituent is resin, though some pieces contain a considerable proportion of bassorin, and others large quantities of ligneous matter. It was formerly used as a stimulant and emmenagogue, but is now scarcely employed. Placed in the cavities of carious teeth, it is said to relieve toothache. The *wood* of the ivy, which is light and porous, is sometimes used for making *issue-peas*.

HELENIUM AUTUMNALE. *False Sunflower. Sneezewort.* An indigenous perennial herb, from three to seven feet high, with large golden-yellow compound flowers, which appear in August. It grows in all parts of the United States, flourishing best in meadows, moist fields, and other low grounds. All parts of it are bitter and somewhat acrid, and, when snuffed up the nostrils in the state of powder, produce violent sneezing. The leaves and flowers have been recommended as an excellent errhine. Clayton says that the plant is thought to be useful in intermittent fever.

HELLEBORUS FŒTIDUS. *Bear's-foot.* This is a perennial European plant, growing in shady places, and flowering in March and April. It derived its botanical designation from its offensive odour. The leaves, which are the part used, have a bitterish, pungent, and acrid taste, and when chewed excoriate the mouth. The foot-stalks are still more acrid. This species of hellebore is said by Allioni to be the most acrid and energetic of the plants belonging to the genus. It is powerfully emetic and cathartic, and in very large doses produces dangerous effects. It has long been used in Great Britain as a domestic remedy for worms, and was brought to the notice of the profession by Dr. Bisset, who found it an efficacious anthelmintic, and prescribed it also in asthma, hysteria, and hypochondriasis. M. Decerfs has known it to cause the expulsion of tænia. It is given in powder or decoction. The dose for a child from two to six years old is from five grains to a scruple of the dried leaves, or a fluidounce of the decoction made by boiling a drachm of the dried leaves in half a pint of water. This quantity should be repeated morning and night for two or three days in succession. A syrup made from the juice of the green leaves is used in England.

HELONIAS DIOICA. *False Unicorn Plant. Star-wort.* This is a small perennial herbaceous plant, growing in most parts of the United States, in shady and hilly situations.

The root, which is the part used, is bulbous. Pursh says that it is used as a remedy in colic. Dr. Braman has found it peculiarly efficacious in atony of the generative organs, and has obtained great advantages from it in leucorrhœa. He states the dose of the powdered root at a drachm and a half, three times a day. It may also be given in the forms of syrup and tincture. (*Bost. Med. and Surg. Journ.*, xl. 416.)

HERMODACTYLS. *Hermodactyli.* Under this name are sold in the shops of Europe the roots or bulbs of an uncertain plant, growing in the countries about the eastern extremity of the Mediterranean. By some botanists the plant is considered a species of *Colchicum*, and the *C. variegatum*, a native of the South of Europe and the Levant, is particularly indicated by Fée, Geiger, and others; while by authors not less eminent, the roots are confidently referred to *Iris tuberosa*. They certainly bear a considerable resemblance to the bulb of Colchicum autumnale, being heart-shaped, channelled on one side, convex on the other, and from half an inch to an inch in length, by nearly as much in breadth. As found in the shops, they are destitute of the outer coat, of a dirty yellowish or brownish colour externally, white and amylaceous within, inodorous, and nearly tasteless, though sometimes slightly acrid. They are often worm-eaten. Their chief constituent is starch, and they contain no veratria or colchicia. From this latter circumstance, and from their insipidity, it has been inferred that they are probably not derived from a species of Colchicum; but Geiger observes that they may have lost their acrimony by age. They are in fact almost without action upon the system, and are now seldom used; never, we believe, in this country. It is doubted whether they are the *hermodactyli* of the ancients, which were certainly a powerful medicine, operating very much in the same manner as our colchicum, and like it proving useful in gout and rheumatism. Pereira describes a bitter variety of hermodactyls, which was brought from India by Dr. Royle. The bulbs are smaller and darker than the others, and have externally a striped or reticulated appearance. From their bitter taste they are probably more active.

HIBISCUS ABELMOSCHUS. *Abelmoschus moschatus.* Wight and Arnott. An evergreen shrub, growing in Egypt, and in the East and West Indies, and affording the seeds known under the names of *semen Abelmoschi, alceæ Ægyptiacæ* and *grana moschata*. These are of about the same size as flaxseed, kidney-shaped, striated, of a grayish-brown colour, of an odour like that of musk, and of a warm somewhat spicy taste. They were formerly considered stimulant and antispasmodic; but are now used only in perfumery. The Arabs flavour their coffee with them. They are said to be employed in the adulteration of musk. Another species, *Hibiscus esculentus*, or *Abelmoschus esculentus* of Wight and Arnott, is cultivated, under the name of *okra*, *bendee*, or *gombo*, in various parts of the world, for the sake of its fruit, which abounds in mucilage, and is used for thickening soup. The leaves are sometimes employed for preparing emollient poultices.

HURA BRASILIENSIS. *Assacou.* Hura Brasiliensis of Martius is a Brazilian tree belonging to the family of Euphorbiaceæ, and known to the natives of the country it inhabits by the name of *assacou*. Another species of the same genus, *H. crepitans*, growing in the W. Indies, and characterized by the tendency of its fruit to break when ripe with violence into several pieces, and thus scatter the seeds, has long been known as an acrid emeto-cathartic, capable in large doses of acting as a violent poison. The fresh juice, the seeds, and a decoction of the bark, all have these properties, which, in fact, belong in a greater or less degree to most of the Euphorbiaceæ: and, as in other members of the same family, an oil expressed from the seeds is actively purgative. It is highly probable that the Hura Brasiliensis is similar in all these respects to its congener. Martius states that the juice is anthelmintic, and employed to intoxicate fish. But attention has recently been especially attracted to the plant, in consequence of reports favourable to its efficacy in that terrible scourge of Brazil, the elephantiasis or leprosy of the country. These reports were received by the Academy of Medicine, of Paris, from the French Consul in one of the towns of Para, of which province the natives are said to regard the remedy as a specific in the complaint referred to. Experiments have been made by the Brazilian physicians, and it is said with favourable results, though complete cures have not been obtained. The fact is, that various acrid emeto-cathartic medicines, capable also of producing diaphoresis, have been more or less useful in elephantiasis, as the Calotropis gigantea, and one or more species of Ionidium; and it is probable that the assacou acts in a similar manner, and with similar results. The milky juice of the plant, and an infusion or decoction of the bark are used. The juice is extremely acrid, producing on the skin, when applied to it, an erysipelatous redness and a pustular eruption; and the natives are said to employ it in the preparation of a poison. A grain of the juice made into a pill, or a scruple of the bark infused in a pint of water, is given every day, and gradually increased as the stomach and bowels will bear it. Every week an emetic preparation is administered, made by boiling half an ounce of the bark in a pint of water to half a pint, to which twelve

drops of the juice are added. Every second or third day the patient takes a bath, consisting of a saturated infusion of the bark. (*Journ. de Pharm. et de Chim.*, xiv. 424.)

HYDRANGEA ARBORESCENS. *Common Hydrangea. Seven Barks.* This species of Hydrangea is indigenous, growing in shady places, in the woods and on the banks of streams throughout the middle and southern States. It is a shrub from four to eight feet high, with ovate or cordate leaves, from three to six inches long, generally acuminate, serrately toothed, and slightly pubescent or nearly glabrous. The flowers are in fastigiate cymes, and appear in July. For a particular botanical description of the plant, the reader is referred to Torrey and Gray's *Flora of North America* (i. 591). The root, which is the part used, consists of a caudex, from which proceed numerous radicles, from the thickness of a quill to that of the finger or more. For use it should be cut into transverse pieces when fresh, and then dried. The taste is aromatic, pungent, and not unpleasant. The root was analyzed by Mr. Laidley, of Richmond, Va., who found in it gum, albumen, starch, resin, and various salts, among which was a protosalt of iron. (*Am. Journ. of Pharm.*, xxiv. 20.) Attention was first called to it as a remedy in the *N. J. Med. Report. and Trans.* for Oct., 1850 (p. 44), by Dr. S. W. Butler, whose father, Dr. E. Butler, long residing as a missionary among the Cherokee Indians, employed it with great apparent advantage in their calculous complaints. Dr. Butler used it in the form of decoction, or of a syrup made from the decoction with sugar or honey. A strong syrup may be given in the dose of a teaspoonful three times a day. In over-doses it occasions vertigo, oppression of the chest, &c.

HYDRASTIS CANADENSIS. *Yellow root. Orange root.* This is an indigenous plant, growing in different parts of the United States, but most abundantly beyond the Alleghanies. It flourishes best in rich shady woods. It has a perennial root, and an herbaceous stem, from six inches to a foot high, with two unequal leaves, and a single terminal whitish or rose-coloured flower. The root consists of a tortuous caudex and numerous long fibres, and is of a bright-yellow colour. It is juicy in the recent state, and loses much of its weight when dried. It has a strong, somewhat narcotic odour, and an exceedingly bitter taste. Examined by Mr. Alfred A. B. Durand, of Philadelphia, it was found to contain albumen, starch, fatty matter, resin, yellow colouring matter, sugar, lignin, and various salts. He also discovered a peculiar nitrogenous, crystallizable substance, for which he proposes the provisional name of *hydrastin*, until it shall be determined whether it is, as he suspects, an organic alkali. (*Am. Journ. of Pharm.*, xxiii. 113.) The root probably possesses the ordinary virtues of the vegetable bitters, and is said to be popularly employed as a tonic in some parts of the country. In the form of infusion, it has been used in the Western States as a topical application in ophthalmia; and the Indians are said to employ it in the same manner in old ulcers of the legs. The notion of its efficacy in cancer, originating in a report which reached the late Professor Barton, that it was used in the cure of this complaint by the Cherokees, is probably altogether groundless. Dr. U. E. Ewing, of Lexington, Ky., and Dr. D. M. McCann, of Martinsburgh, Ohio, have recommended an infusion or decoction of the root as an injection in gonorrhœa. Dr. McCann made the decoction in the proportion of a drachm of the dried root to a pint of water, and injected a syringe-full three times a day. Dr. Ewing used the infusion with the addition of *sulphate of copper*. (*Med. Examiner*, N. S., vii. 733.) Dr. P. C. Gooch has subsequently used it in five cases, and obtained no good effect whatever. (*Am. Journ. of Med. Sci.*, N. S., xxiii. 286.) The Indians employ the juice of the root to stain their clothing, &c., yellow.

HYDRIODIC ACID. *Acidum Hydriodicum.* Dr. Andrew Buchanan, of Glasgow, recommends the following formula for obtaining this acid for medicinal purposes. Take of iodide of potassium 330 grains, tartaric acid 264 grains. Dissolve the salts, separately, each in a fluidounce and a half of distilled water, and mix the solutions. Filter the liquor, in order to separate the bitartrate of potassa which precipitates, and add to it sufficient distilled water to make the whole measure fifty fluidrachms. When of this strength, each fluidrachm of the acid contains five grains of iodine. The solution of hydriodic acid, when thus prepared, is sufficiently pure for medicinal use, although containing a little cream of tartar in solution. At first it is limpid, or has only a slight yellow tinge; but on keeping it assumes, first a wine-yellow, and afterwards a beautiful red colour, in consequence of the disengagement of iodine.

Dr. Buchanan considers uncombined iodine to be an irritant, and its alterative powers, when these are manifested, to depend upon its conversion into hydriodic acid, of a strength sufficiently moderate to be readily absorbed, and to pass into the current of the circulation. He conceives that when iodine is given, and proves to be absorbed, it is by being first converted into hydriodic acid by hydrogen derived from the gastric juice, or from the tissues of the stomach, which latter undergo corrosion. A desire to avoid this incidental irritant effect led Dr. Buchanan at first to combine the iodine with starch, which he supposes to

furnish the necessary hydrogen while undergoing digestion, and finally to use the hydriodic acid ready formed.

In giving the liquid hydriodic acid according to his formula, Dr. Buchanan begins by exhibiting a few drops, and afterwards increases the dose, first to a fluidrachm and finally to half a fluidounce three times a day, equal to a drachm of iodine daily. This was his ordinary maximum dose, but sometimes he gave a fluidounce three times a day. In all cases the acid was administered sufficiently diluted with water to reduce it to an agreeable sourness, in which state it possesses no irritant action whatever. When, however, the acid has undergone a change of colour, as previously mentioned, Dr. Buchanan uses a solution of starch as a vehicle, in order to divest the free iodine, the presence of which is indicated by this change, of all irritant qualities. Hydriodic acid, when thus used, exhibits the same therapeutic effects as free iodine, with the advantages of having no irritant property, and of affording the means of introducing much larger quantities of iodine into the system through the medium of absorption, than when given in the ordinary form. (*Am. Journ. of Med. Sci.*, xx. 210 and 214, from the *Med. Gazette.*) Dr. Samuel Lewis and Mr. T. J. Husband, of this city, have combined hydriodic acid with several of the organic alkalies, with a view to form new medicinal preparations. (*Am. Journ. of Pharm.*, xvi. 21.)

HYDRIODIC ETHER. *Æther Hydriodicus. Iodide of Ethyle.* This ether may be obtained by gradually and cautiously mixing five parts of alcohol, ten of iodine, and one of phosphorus, and distilling. The phosphorus is converted into phosphorous acid by the oxygen of the alcohol, and the liberated ethyle unites with the iodine. Hydriodic ether is a colourless non-inflammable liquid, insoluble in water, with a penetrating ethereal odour and pungent taste. Its density is 1·92, and boiling point 158° F. When exposed to the air it becomes red from the liberation of iodine, a change which is prevented by adding to the bottle containing the ether, a globule of mercury. Being an iodide of ethyle, its formula is C_4H_5I. M. Huette has proposed this ether as a medicinal agent, to be used by inhalation, placed under a layer of water. Fifteen or twenty inspirations suffice to impregnate the system with iodine. Its physiological effects appear to be those of an antispasmodic and general stimulant. It increases the appetite, renders the pulse fuller, and gives vivacity to the feelings and activity to the intellect. M. Huette considers it a suitable preparation for bringing the system rapidly under the influence of iodine, and by any desired dose. (See *Am. Journ. of Pharm.*, xxiii. 156.)

HYDROCOTYLE ASIATICA. *Thick-leaved Pennywort. Bevilacqua.* Boileau. This is a small umbelliferous plant, with a trailing stem, and, in consequence of the shape of its leaves, bearing some resemblance to the violet. It grows in moist grounds in India, Southern Africa, and the Islands of the Indian Ocean. It has long been ranked among the medicinal plants of India, where it has been used as an alterative to purify the blood in children. It has been supposed to possess diuretic properties; and, according to Ainslie, is employed in infusion with fenugreek in fever and bowel complaints. But it has recently attracted considerable attention, from the claims strongly urged in its favour as a remedy in that most obstinate affection often called leprosy, but more correctly elephantiasis of the Greeks. It was first employed in this complaint by Dr. Boileau, of the Island of Mauritius, who was himself a victim of the disease, and had resorted to this remedy under the false impression that it might be identical or analogous with the *cuichunchulli*. He was so much pleased with its effects that he was induced to try it upon others; and a great number of lepers were put under its influence. All the cases were arrested, many were benefited, and in some the disease almost disappeared. The statements of Dr. Boileau have been supported by those of M. Lépine, of Pondicherry, and the medicine would certainly seem to merit a thorough investigation. Dr. Boileau, probably at first in ignorance of its proper botanical title, gave it the name of *bevilacqua*. He used it in powder, infusion, and syrup. An ounce of the dried plant may be given daily in the form of infusion, made with a pint of water. This should be continued for several weeks, and combined with baths, and attention to the state of the bowels. After this preparation, the syrup is to be given in spoonful doses three times a day, to be gradually increased after three weeks, if no improvement has taken place, to eight spoonfuls daily. The powder may be added to the syrup, if deemed necessary, in the dose, at first of fifteen grains, increased cautiously to a drachm. (*Journ. de Pharm.*, 3e *sér.*, xxiv. 424, and xxv. 153.)

HYDROCYANIC ETHER. *Æther Hydrocyanicus. Hydrocyanate of Etherine. Cyanuret of Ethyle.* This ether was discovered by Pelouze. It is formed by distilling a mixture of sulphovinate of baryta and cyanuret of potassium. It is a colourless liquid of a penetrating garlic odour, soluble in alcohol and ether, sparingly soluble in water, boiling at 180°, and weighing specifically 0·78. It is very poisonous, but less so than hydrocyanic acid, with which it agrees in therapeutic action and dose.

HYPERICUM PERFORATUM. *St. John's Wort.* A perennial herb, abundant both in Europe and this country, often covering whole fields, and proving extremely troublesome to farmers. It is usually from one to two feet high, with leaves which, from the presence of numerous transparent vesicles, appear as if perforated, and have hence given origin to the botanical designation of the plant. The flowers, which are numerous and of a deep-yellow colour, appear during the summer from June to August. The flowering summits are the parts used, though the unripe capsules are possessed of the virtues of the plant in an equal degree, and the seeds are said to be even stronger. St. John's wort has a peculiar balsamic odour, which is rendered more sensible by rubbing or bruising the plant. Its taste is bitter, resinous, and somewhat astringent. It imparts a yellow colour to cold water, and reddens alcohol and the fixed oils Its chief constituents are volatile oil, a resinous substance, tannin, and colouring matter. As a medicine it was in high repute among the ancients, and the earlier modern physicians. Among the complaints for which it was used were hysteria, mania, intermittent fever, dysentery, gravel, hemorrhages, pectoral complaints, worms, and jaundice; but it was, perhaps, most highly esteemed as a remedy in wounds and bruises, for which it was employed both internally and externally. It is difficult to ascertain its exact value as a remedy; but from its sensible properties, and from the character of the complaints in which it has been thought useful, it may be considered, independently of its astringency, as somewhat analogous in medical power to the turpentines. It formerly enjoyed great reputation for the cure of demoniacs; and the superstition still lingers among the vulgar in some countries. At present the plant is scarcely used except as a domestic remedy. The summits were given in the dose of two drachms or more. A preparation was at one time officinal, under the name of *oleum hyperici*, made by treating them with a fixed oil. It has a red colour, and is still used in many families as a sovereign remedy for bruises.

HYPOSULPHITE OF SODA. *Sodæ Hyposulphis.* This salt is readily prepared, according to Walchner, by mixing a pound of dry carbonate of soda, in fine powder, with five ounces of sulphur, heating the mixture gradually in a porcelain vessel until the sulphur melts, and stirring the agglutinated mass, still kept hot, in order that every portion of it may come in contact with the air. The sulphuret of sodium, first formed, is thus converted into sulphite of soda. This is dissolved in water, and the filtered solution, being boiled with sulphur, becomes one of hyposulphite of soda, from which, on concentration, the salt is deposited in large, colourless, transparent crystals, which are freely soluble in water, but insoluble in alcohol. Hyposulphite of soda is largely used by daguerreotypists for the purpose of dissolving the sensitive coating of iodide of silver from the plate, after the action of the light, and thus fixing the image already formed.

Latterly, this salt has been used in skin diseases, and especially in that form of stomach disease attended with yeasty vomiting. It is particularly efficacious in the treatment of violent irritations of the skin; but is also useful in visceral obstructions. It may be prepared as a *syrup* by dissolving an ounce and a half of the salt in seven fluidounces of water, and adding sixteen ounces of sugar. Of this two teaspoonfuls may be taken three times a day. (Mouchon, *Ann. de Thérap.*, 1852, 111.) Dr. R. Neale, of London, has used this salt with great advantage in an obstinate case of yeasty vomiting, in which the vomited matter showed, under the microscope, numerous sarcinæ ventriculi. He gave it in the dose of from ten to fifteen grains three times a day, in half a fluidounce of infusion of quassia. (*Braithwaite's Retrospect*, xxviii. 131.)

HYPOSULPHITE OF SODA AND SILVER. *Sodæ et Argenti Hyposulphis.* This double salt may be prepared by dissolving freshly precipitated oxide of silver in a solution of hyposulphite of soda, and evaporating the solution. It is in the form of minute crystals, very soluble in water, but insoluble in alcohol, and possessing a very sweet taste. Its solution, protected from the light, undergoes no change, and, when quite pure, does not discolour the skin or linen. M. Delioux, of Rochefort, has tried this salt externally only, and thinks it acts like nitrate of silver, but more mildly. He used it with advantage in urethral discharges especially, dissolved in the proportion of one or two parts in two hundred of water. (*B. and F. Medico-Chirurg. Review*, Am. ed., April, 1853, p. 447, from the *Bull. de Thérap.*)

HYSSOPUS OFFICINALIS. *Hyssop.* This is a labiate plant, belonging to the class and order Didynamia Gymnospermia of the sexual system. It is perennial, with numerous erect, quadrangular, somewhat branching stems, which are woody in their inferior portion, about two feet high, and furnished with opposite, sessile, lanceolate-linear, pointed, punctate leaves. The flowers are violet-coloured or blue, sometimes white, turned chiefly to one side, and arranged in half verticillated, terminal, leafy spikes. The upper lip of the corolla is roundish and notched at the apex, the lower is divided into three segments, of which the undermost is obovate.

Common hyssop is a native of the continent of Europe, where, as well as in this country, it is also cultivated in gardens. The flowering summits and leaves are the parts used. They have an agreeable aromatic odour, and a warm, pungent, bitterish taste. These properties they owe to an essential oil, which may be obtained separate by distillation with water, and rises also with alcohol. Hyssop is a warm gently stimulant aromatic, applicable to the same cases with the other labiate plants. Its infusion has been much employed in chronic catarrhs, especially in old people, and those of a debilitated habit of body. It acts by facilitating the expectoration of the mucus which is too abundantly secreted. In this country, however, it is very seldom used by regular practitioners.

IBERIS AMARA. *Bitter candytuft.* A small herbaceous plant, indigenous in Europe, where it is cultivated in gardens, on account of its bright milk-white flowers. The leaves, stem, and root are said to possess medicinal properties; but the seeds are the most efficacious. The plant appears to have been employed by the ancients in rheumatism, gout, and other diseases. It has recently been brought into notice by Dr. Silvester, who ascribes to the late Dr. Williams, of St. Thomas's Hospital, England, the merit of having first ascertained its real therapeutic value. In large doses it produces giddiness, nausea, and diarrhœa; but its virtues do not seem to be associated with any perceptible physiological effect. It is thought to exercise a happy influence over the excited actions of the heart, and is especially useful in hypertrophy. Much advantage is also said to have accrued from it in asthma, bronchitis, and dropsy. The dose of the seeds is from one to three grains. (*Prov. Med. and Surg. Journ.*, July 28, 1847.)

ILEX. *Holly.* Several species of Ilex are employed in different parts of the world. The *I. Aquifolium*, or *common European holly*, has attracted much attention in France. It is usually a shrub, but in some places attains the magnitude of a middling-sized tree. Different parts of it are used. The viscid substance called birdlime is prepared from the *inner bark.* The *leaves*, which are of a bitter, somewhat austere taste, were formerly much esteemed as a diaphoretic, and in the form of infusion were employed in catarrh, pleurisy, small-pox, gout, &c. A few years since they gained some reputation in France as a cure for intermittents, and were considered by some as equal to Peruvian bark; but the first reports in their favour have not been fully confirmed. They were used in powder, in the dose of a drachm two hours before the paroxysm; and this dose was sometimes repeated frequently during the apyrexia. Their febrifuge virtues are said to depend on a bitter principle, for which the name of *ilicin* has been proposed. M. Labourdais obtained this principle by boiling a filtered decoction of holly leaves with animal charcoal, allowing the charcoal to subside, washing it, then treating it with alcohol, filtering off the alcoholic solution, and evaporating it to a syrupy consistence. The liquid thus obtained was very bitter, and on being allowed to evaporate spontaneously, yielded an amorphous substance, having the appearance of gelatin, which was the principle in question. (*Am. Journ. of Pharm.*, xxi. 89, from *Ann. de Chim. et de Phys.*) The *berries* are about the size of a pea, red and bitter, and are said to be purgative, emetic, and diuretic. Ten or twelve of them will usually act on the bowels, and sometimes vomit. Their expressed juice has been used in jaundice.

The *Ilex opaca*, or *American holly*, is a middling-sized evergreen tree, growing throughout the Atlantic section of the United States, and especially abundant in New Jersey. It is so similar to the European plant, that it is, by some writers, considered as the same species. It is said to possess the same medical properties.

The *Ilex Paraguaiensis*, or *I. Mate* of St. Hilaire, yields the celebrated *Paraguay tea*, so extensively consumed as a beverage in the interior of South America. The leaves, which are the part used, have a balsamic odour and a bitter taste, and are usually at first disagreeable to the palate. They have a pleasant corroborant effect upon the stomach; but, when very largely taken, are said to purge and vomit. They are used in the form of infusion. According to the experiments of Stenhouse, these leaves contain a principle identical with the caffein of tea and of coffee; and like them contain also tannic acid; so that a close analogy exists in composition as well as effects between these three products, so little allied botanically, and so far separated in place of growth.

The *Ilex vomitoria* of Aiton and Linn., the *I. Cassina* of Michaux, is a handsome evergreen shrub, growing in our Southern States, and especially abundant along the southern coast of Florida. It is the *cassina* of the Indians, who formerly employed a decoction made from the toasted leaves, called *black drink*, both as a medicine, and as a drink of etiquette at their councils. It acts as an emetic. The leaves of the *Ilex Dahoon* of Walter and Michaux have similar properties, and are also said to have entered into the composition of the black drink.

ILLICIUM FLORIDANUM. *Florida Anise-tree.* This is an evergreen shrub or small tree, growing in Florida, along the coast which bounds the Gulf of Mexico. The bark,

leaves, and probably also the seed vessels, are endowed with a spicy odour and taste, analogous to those of anise, and might, perhaps, be used for the same purposes as that aromatic. It is a question worthy of investigation whether the capsules of this plant might not be substituted for those of the *Illicium anisatum* or *star aniseed*, which yield much of the oil used in this country under the name of *oil of anise*. (See *Anisum*.) Another species, the *I. parviflorum*, a shrub found by Michaux in the hilly regions of Georgia and Carolina, has a flavour closely resembling that of sassafras root.

IMPATIENS FULVA and IMPATIENS PALLIDA. *Touch-me-not. Jewel-weed. Balsam-weed.* These two species of Impatiens are indigenous, annual, succulent plants, from two to four feet high, growing in low moist grounds in all parts of the Union, and flowering in July and August. They may be known by their tender, juicy, almost transparent stems: by their yellow flowers, which in one species are pale and sparingly punctate, in the other, are deeper coloured and crowded with dark spots; and by their capsules, which burst elastically, and curl up with the slightest pressure. They probably possess properties similar to those of the *I. Noli-me-tangere* of Europe, which has an acrid burning taste, and, when taken internally, acts as an emetic, cathartic, and diuretic, though considered dangerous, and therefore little used. The late Dr. Ruan, of Philadelphia, informed us that he had employed with great advantage, in piles, an ointment made by boiling the American plants, in their recent state, in lard. The flowers may be used for dyeing yellow. The *I. Balsamina* or *balsam-weed, touch-me-not, &c.* of the gardens, resembles the other species in its effects.

IMPERATORIA OSTRUTHIUM. *Masterwort.* An umbelliferous plant, indigenous in the South of Europe. The root has a strong odour, similar to that of angelica, and a pungent, biting, aromatic taste, attended with a flow of saliva, and followed by a glowing warmth which remains long in the mouth. It was formerly considered alexipharmic, stomachic, corroborant, emmenagogue, diuretic, and diaphoretic; and was used in a wide circle of complaints with so much supposed success as to have gained for it the title of *divinum remedium*. The fact, however, appears to be, that it is merely a stimulant aromatic, analogous but inferior to angelica, which has nearly superseded it in European practice. In this country, it is unknown as a remedy, and its vulgar name has been applied to another plant.

INDELIBLE INK. This is prepared by dissolving two drachms of nitrate of silver and a drachm of gum Arabic in a fluidounce of distilled water, coloured with a little Indian ink. It is used for writing with a pen on linen and muslin. The place to be marked is prepared by being moistened with a solution of two ounces of crystallized carbonate of soda and two drachms of gum Arabic in four fluidounces of water, and then dried. The alkaline solution serves to decompose the nitrate, and to protect the cloth from the action of the free nitric acid. At the end of twenty-four hours, the spot is to be washed.

Mr. Redwood, of London, proposes the following indelible ink, not requiring the use of a mordant. Dissolve an ounce of nitrate of silver, and an ounce and a half of crystallized carbonate of soda, separately, in distilled water, and mix the solutions. Wash the precipitated carbonate of silver, and, having introduced it, still moist, into a Wedgwood mortar, rub it with eight scruples of tartaric acid, until effervescence ceases. Then add strong solution of ammonia, just sufficient to dissolve the tartrate of silver formed (about two fluidounces). Lastly, having mixed in half a fluidounce of archil, half an ounce of white sugar, and an ounce and a half of powdered gum Arabic, add sufficient distilled water to make the whole measure six fluidounces. M. Soubeiran formerly published the following formula for indelible ink, which he considers simpler than Mr. Redwood's. Dissolve 8 parts of crystallized nitrate of silver, 3 of nitrate of copper, and 4 of carbonate of soda, in 100 parts of water of ammonia, and add to the solution a small quantity of gum. The marks, produced by nitrate of silver on linen or muslin, may be completely removed by moistening them with a solution of corrosive sublimate in 30 parts of distilled water, and afterwards washing them with ordinary water.

M. Jules Guiller has devised the three following formulæ for marking inks for linen. 1. Nitrate of silver 11 parts; distilled water 85; powdered gum Arabic 20; carbonate of soda 22; solution of ammonia 20. Dissolve the carbonate of soda in the water, rubbing the solution with the gum, and the nitrate of silver in the ammonia. Mix the solutions, and gradually heat the mixture in a flask until it boils. This ink flows readily from a pen. 2. Nitrate of silver 5 parts; distilled water 12; powdered gum Arabic 5; carbonate of soda 7; solution of ammonia 10. The ingredients are treated as in the preceding formula, with the exception that the mixed solution is heated until it becomes of a very dark colour, and is reduced about one-twentieth in volume by evaporation. This ink is suitable for marking on linen with stamps. 3. Nitrate of silver 17 parts; distilled water 85; pow-

dered gum Arabic 20; carbonate of soda 22; solution of ammonia 42; sulphate of copper 33. Dissolve the nitrate of silver in the ammonia, the carbonate of soda in 25 parts of the water, and the gum in the remaining 60 of the water. Then mix with the soda solution, first the gum solution, and afterwards the silver solution. Lastly, add the sulphate of copper. This ink has a blue, instead of the dark-brown colour of the others. (See *Am. Journ. of Pharm.*, Jan. 1853, p. 33.)

Herberger recommends the following indelible ink for other purposes than marking linen. Dissolve wheat gluten, carefully freed from starch, in a little weak acetic acid, and dilute the solution with rain water, so as to have about the strength of wine vinegar. For every four ounces of the solution, add ten grains of the best lampblack, two grains of indigo, and a little oil of cloves. This ink has a beautiful black colour, and cannot be removed by chlorine or dilute acids. (*Chem. Gaz.*, No. 70, p. 394.)

INDIAN RED. A purplish-red pigment, brought from the island of Ormus in the Persian Gulf. It is a *red ochre*, and owes its colour to the red oxide of iron.

INDIAN YELLOW. This is a pigment manufactured from a yellow substance from India, called *purree*. Purree occurs in commerce in balls, of from three to four ounces in weight, which are dark-brown externally, and deep-orange within. It has a peculiar smell, closely resembling that of castor. This circumstance gave rise to the belief that it was of animal origin; but Dr. Stenhouse, who examined it chemically, finds that it contains no nitrogen, and from this and other facts is led to the opinion that it is a vegetable substance. Upon analysis he found it to consist of magnesia, united with a peculiar acid, which he names purreic (*euxanthic acid* of Erdmann), and which forms nearly one-half of the crude substance. *Purreic acid* is in small crystals of a light-yellow colour, dissolving sparingly in cold water, pretty readily in boiling water, and abundantly in hot alcohol. It has at first a sweetish, and then a slightly bitter taste, and possesses, in appearance, considerable resemblance to berberin. When acted upon by boiling nitric acid, it is finally converted into a new acid, crystallizing in yellow needles, called by Erdmann, *oxypicric acid*. The ultimate constituents of purreic acid are carbon, hydrogen, and oxygen. From his examination of purree, Dr. Stenhouse concludes that it is probably the juice of some plant, saturated with magnesia, and boiled down to a solid consistence. (See his paper in the *Philos. Mag.*, xxv. 321.)

INDIGO. This well-known and highly important dye-stuff is obtained from various species of *Indigofera*, especially *I. tinctoria*, *I. Anil*, and *I. argentea;* and is said to be afforded also by other plants, such as *Wrightia tinctoria*, *Polygonum tinctorium*, *Galega tinctoria*, &c. In the process of preparing it, the plant is macerated in water; fermentation takes place; the liquor becomes of a greenish colour, and in due time is decanted; the colouring principle dissolved by the water absorbs oxygen from the air, and assumes a blue colour, becoming at the same time insoluble; a gradual precipitation takes place, favoured by the addition of lime-water or an alkaline solution; and finally the precipitated matter, having been washed upon linen filters, is dried, shaped usually into cubical masses, and sent into market. Most of the indigo consumed in dyeing is brought from the East Indies, though considerable quantities are imported also from Guatemala, and the northern coast of South America. It is of an intensely blue colour, but assumes a coppery or bronze hue when rubbed by a smooth hard body, as the nail. Heated to 550°, it emits a reddish-violet vapour, which condenses in minute crystals. It is insoluble in water, or alcohol, but is readily dissolved by sulphuric acid, which, without destroying its blue colour, so far alters its nature as to render it freely soluble in water, and thus affords a convenient method of applying it to the purposes of dyeing. The solution in sulphuric acid is kept in the shops under the name of *sulphate of indigo*. According to Berzelius, indigo contains, among other ingredients, four distinct principles:—1. a substance resembling gluten; 2. a brown colouring substance; 3. a red colouring substance; and 4. a blue colouring substance, which is the principle upon which its value as a material for dyeing depends, and which seldom constitutes so much as one-half of the indigo of commerce. This blue colouring matter is called *indigotin*. By deoxidizing agents it is deprived of its blue colour, which it recovers by exposure to the air, in consequence of the absorption of oxygen. Chlorine also destroys the blue colour. M. Preisser has concluded, from an elaborate examination of the *colouring principles* of plants, 1. that these principles are colourless in the young plants, 2. that they acquire colour by combination with oxygen, 3. that all the colouring matters, extracted from any one plant, are produced by the oxidation in different degrees of a single principle, 4. that they are deprived of colour by substances having a strong affinity for oxygen, and reacquire it by contact with oxidizing bodies, and 5. that these colouring principles are acids, and the lakes which they form genuine salts. (*Journ. de Pharm.*, 3*e sér.*, v. 263.) For modes of testing the value of any specimen of indigo, the reader is referred to the *Chemical Gazette* (vii. 463, viii. 443, and x. 159); also to the *Am. Journ. of Pharm.* (xxv. 223).

Indigo has been introduced to the notice of the profession as a remedial agent. It was at first chiefly employed by the German physicians, from whose statements our knowledge of its physiological action and therapeutical application was derived. Though without odour and taste, it is said, in most individuals, to produce nausea and vomiting, frequently to operate upon the bowels, giving a bluish-black colour to the stools, to render the urine of a dark-violet or dark-green colour, without increasing its quantity, and sometimes to stimulate the secretory function of the uterus. From these statements it would appear to act as an irritant to the alimentary mucous membrane. The character of its general influence upon the system has not been well ascertained. In some instances, it is asserted to have been given in very large doses without any obvious effect. The complaints in which it has been employed, with supposed advantage, are epilepsy, infantile convulsions, chorea, hysteria, and amenorrhœa. It is given, usually, in connexion with some aromatic powder, in the dose of a scruple three times a day, which may be increased to a drachm or more; and from half an ounce to an ounce has daily been employed for months together without disadvantage. (See *Am. Journ. of Med. Sci.*, xx. 487.)

IODIDE OF AMMONIUM. *Ammonii Iodidum. Hydriodate of Ammonia.* This salt is best prepared by the following method, devised by Mr. John A. Spencer, of London. Add to a portion of iodine, placed in a flask with a little water, a solution of hydrosulphate of ammonia, until the mixture loses its red colour, and is turbid from the separation of sulphur only. Shake the flask, which causes the sulphur, for the most part, to agglomerate: and, having poured off the liquid, boil it until all odour of sulphuretted hydrogen and of ammonia is lost. Then filter the liquid, and, constantly stirring, evaporate it, first with a naked flame until it becomes pasty, and then in a water bath until it forms a dry salt. Iodide of ammonium, as thus prepared, is a crystalline powder, which is beautifully white at first, but becomes, in a few weeks, yellowish, and, at last, brown. It may, however, be easily restored by dissolving the coloured salt in water, treating the solution with a little sulphuretted hydrogen water, until it is rendered colourless, filtering, and evaporating to dryness. (See *Am. Journ. of Pharm.*, March, 1853, p. 134.) Latterly, this salt has been used as a substitute for iodide of potassium. By Dr. Pennock it is considered as a good remedy in certain cases of lepra and psoriasis, made into an ointment. (*Am. Journ. of Med. Sci.*, xv. 374.) The proportions employed are from a scruple to a drachm of the salt to an ounce of lard; the weaker preparation being used when the disease is recent, the stronger when it is chronic. The ointment is employed in frictions in the amount of half an ounce, morning and evening. As the iodide is decomposed by the air, the ointment should be kept in well stopped bottles. Iodide of ammonium is used in photography.

IODIDE OF BARIUM. *Barii Iodidum.* This compound may be formed by double decomposition, by adding carbonate of baryta to a boiling solution of iodide of iron. M. Henry, jun., obtains it by decomposing a solution of sulphuret of barium (see *page* 908) by a concentrated alcoholic solution of iodine. Sulphur is precipitated, which is separated by filtration, and iodide of barium formed in solution, from which it is obtained in the solid state by a rapid evaporation to dryness. It crystallizes in small, colourless needles, which deliquesce slightly, and are very soluble in water. The solution promptly undergoes decomposition by exposure to the air, carbonate of baryta being precipitated, and iodine set free, which colours the solution. It has been used with advantage by Jahn, as an alterative, in scrofulous affections and morbid growths. Lugol employed it in scrofulous enlargements. The dose is the eighth of a grain three times a day, gradually increased to three grains. Biett applied it to scrofulous swellings in the form of ointment, made with four grains of the iodide to an ounce of lard.

IODIDE OF SILVER. *Argenti Iodidum.* This compound is formed by double decomposition, by adding a solution of iodide of potassium to one of nitrate of silver. It is a greenish-yellow powder, nearly insoluble in ammonia. It possesses the general medical properties of nitrate of silver, and, according to Dr. Charles Patterson, of Dublin, may be used without any danger of producing the discoloration of skin which sometimes follows the use of that salt. Dr. Patterson found it generally successful in curing the stomach affections of the Irish peasantry, in the treatment of which nitrate of silver had been previously found useful. He succeeded with it in curing several cases of hooping-cough in a short time, and in greatly relieving a case of dysmenorrhœa of three years' standing. Its effects in epilepsy were least satisfactory. The dose is one or two grains, three times a day, given in the form of pill; for children, from an eighth to a fourth of a grain, according to the age.

IODIDE OF STARCH. Dr. A. Buchanan, of Glasgow, proposed this compound as a means of administering iodine in large doses without causing irritation of the stomach. He prepares it by triturating twenty-four grains of iodine with a little water, adding gradually an ounce of very finely powdered starch, and continuing the trituration until

the compound assumes a uniform blue colour. The iodide is then dried by a gentle heat, and kept in a well stopped bottle. The dose is a heaped teaspoonful, given in water gruel, three times a day, and afterwards increased to a tablespoonful. No nicety is necessary in apportioning the dose. In some cases Dr. Buchanan has given half ounce doses of the iodide three times a day, immediately increased to an ounce. Exhibited in this state of combination, iodine produces, according to this writer, little or no irritation of the alimentary canal; but is freely absorbed, as is proved by its detection in large quantity in the secretions. Dr. Buchanan conceives that, by means of the starch, the iodine is converted into hydriodic acid, and in this form of combination enters the circulation. He prefers the iodide of starch to any other preparation of iodine for obtaining the alterative apart from the irritant effects of this substance. (*Am. Journ. of Med. Sci.*, xx. 213 and 217.) See *Hydriodic Acid*, page 1341.

It is a point of importance to have the iodide of starch soluble in water. This advantage is gained by roasting the starch moderately, whereby it is converted into dextrine, before it is mixed with the iodine. The process of M. Magnes-Lahens, of Toulouse, with whom this plan originated, is as follows. Take of iodine *one part*, starch, properly roasted and afterwards exposed to the air to recover its original hygrometric state, *nine parts*. Reduce the iodine to fine powder, and, by a rapid trituration, rub the starch with it, added by small portions at a time. Expose the mixture to heat in a closed flask, by means of a water bath, until from being gray, it becomes of an intensely blue colour, and then wash it with alcohol to separate all traces of free iodine. The *soluble iodide of starch*, thus formed, may be converted into a *syrup*, by dissolving 25 parts of it in 325 parts of water, by means of a water bath, and adding to the solution 650 parts of sugar. This syrup is perfectly limpid, entirely exempt from the odour of iodine, and of a splendid violet-blue colour. It contains two and a half per cent. of soluble iodide of starch, and about a quarter of one per cent. of iodine. (*Journ. de Pharm.*, April, 1851, p. 243.)

M. Magnes-Lahens has since abandoned the use of torrefied starch, and the washing with alcohol, and contents himself with making an intimate mixture of iodine and starch, slightly moistened, which he subjects to the heat of a water bath until it is converted into the iodide of starch, forming a solution with water of a magnificent blue colour. The heat, thus regulated, disaggregates the starch, without completely transforming it into dextrine, and gives a preparation, in the form of a black powder, resembling the soluble iodide of starch prepared by M. Quesneville by a secret process. M. Seput, of Constantinople, has also given a formula for this soluble iodide, and for a syrup to be made from it. (See *Journ. de Pharm.*, March, 1852, p. 202.) M. Soubeiran has reported upon these preparations to the Paris Society of Pharmacy, and deems them ineligible on account of their variable strength in iodine, arising from the greater or less loss of this element during the necessary exposure to heat. Nevertheless, as the syrup is called for, he recommends the following process for making it, availing himself of the observations of his predecessors, which he had occasion to cite in his report. The quantities of the ingredients will be stated in French grammes, each of which weighs about fifteen grains. Triturate thoroughly, in a porcelain mortar, 36 grammes of nitric starch with 4½ grammes of iodine, dissolved in three times its weight of ether, and added in successive portions, until, after the evaporation of the greater part of the ether, a blue powder remains. Introduce this into a weighed, stoppered flask, and, having added 520 grammes of water, expose the whole to the heat of a water bath, with the stopper at first removed, in order to complete the dissipation of the ether. Afterwards the stopper is replaced, being loosely tied with a packthread, so as to permit of its being raised without being driven out; and the heat is continued for about an hour and a half, when the iodide of starch will be completely formed. The flask is then weighed, and a quantity of water added to it, equal to that lost by evaporation. Lastly, 1040 grammes of sugar are added to the liquid, and dissolved by a gentle heat. By this formula a syrup is prepared, containing a quarter of one per cent. of iodine, a small part of which is in the state of hydriodic acid. The *nitric starch* is used by M. Soubeiran, because it unites with the iodine in much less time than the ordinary starch. It is made by mixing ordinary starch, in the cold, with 150 parts of water, to which 1 part of nitric acid has been added, and allowing the whole to dry in the open air. Three grains of this syrup, diluted with a pint of water, communicate to the solution a sensible blue tint. This test may serve to determine whether the preparation is of full strength. (*Journ. de Pharm.*, May, 1852, p. 329.) The dose of this syrup is from one to four tablespoonfuls a day.

IODIDE OF ZINC. *Zinci Iodidum.* This iodide may be formed by digesting an excess of zinc, in small pieces, with iodine diffused in water. Combination takes place, and, by evaporation, a deliquescent, very soluble saline mass is obtained, having a metallic styptic taste, resembling that of sulphate of zinc. It may also be obtained by heating in a matrass a mixture of 20 parts of zinc and 170 of iodine, and subliming into a vial. When

thus prepared, it is in the form of white needles. This salt is very liable to undergo spontaneous decomposition.

Iodide of zinc is tonic and astringent. It has been lately tried by Dr. Barlow, in Guy's Hospital, in cases of chorea, scrofula, cachexia, and in some forms of hysteria. (*Med. Times and Gaz.*, Nov., 1853, p. 501.) The best form of administration is *syrup*, to protect it from change, originally proposed by the late Dr. A. T. Thomson, and made on the same plan as the syrup of iodide of iron. (See *page* 1005.) Mr. A. B. Taylor, of Philadelphia, proposes to form it by gently heating, in an evaporating dish, *twelve drachms and two scruples* of iodine, and *an ounce* of finely granulated zinc, with *nine fluidounces* of water, until they unite, filtering the solution, while hot, on *a pound* (avoird.) of sugar, contained in a wide-mouthed bottle holding a little more than a pint, and adding, through the filter, sufficient water to make the whole measure a pint. This syrup is perfectly clear and colourless, is styptic to the taste, and contains a drachm of iodide of zinc in each fluidounce. (*Am. Journ. of Pharm.*, Jan., 1852, p. 33.) The dose of this syrup is from 20 to 50 drops, sufficiently diluted with water, three times a day.

Iodide of zinc has been used for many years as an external application. Dr. J. J. Ross, of Scotland, employed a solution, containing from 10 to 30 grains to the fluidounce of water, with great advantage in enlarged tonsils, applied by means of a piece of sponge tied to a quill. After the use of the solution for some time, he applied the iodide, rendered liquid by deliquescence, by means of a camel's hair brush. A solution containing one or two grains to the fluidounce of water, has been used as an astringent injection in gonorrhœa. An ointment, made of a drachm of the iodide with an ounce of lard, has been proposed by Dr. Ure as a substitute for the ointment of iodide of potassium in the treatment of tumours, applied in the quantity of a drachm twice a day.

IODIDES OF CALOMEL. These iodides, comprising a subiodide and protiodide, were brought forward as remedies by M. Boutigny. They are formed by the action of one eq. of iodine on two and one eqs. severally of calomel, the combination being aided by a gentle heat. Both these iodides are active preparations, and have been employed with success in syphilitic, scrofulous, and cancerous affections. The *subiodide* may be given in pill, in the dose of the twenty-fifth of a grain. The *protiodide* is used externally only, and should be applied with caution. It acts as a caustic, and may be cast into sticks, like nitrate of silver. An ointment may be made of it, by rubbing one part with twenty of fresh lard. A portion of the ointment, the size of a large pea, may be rubbed daily on a scrofulous tumour, in the arm pits, or on the inner part of the thigh. The composition assigned by M. Boutigny to these compounds requires confirmation. (*Ann. de Thérap.*, 1848.)

IODOFORM. *Iodoformum. Teriodide of Formyle.* (C_2HI_3.) This is formed, according to the process of MM. Cornélis and Gille, of Liege, by adding to an alcoholic solution of iodide of potassium, heated to 104° F., chlorinated lime, in successive portions, stirring after each addition, until the liquid ceases to assume a dark-red colour. On cooling, a mass of confused crystals is deposited, consisting of iodoform and iodate of lime. By treating these with boiling alcohol of 90 per cent., the iodoform alone is dissolved; and the alcoholic solution, as it cools, deposits the iodoform in crystals. (*Journ. de Pharm.*, Sept., 1852, p. 196.) It is in the form of yellow crystals, having a strong saffron-like odour, insoluble in water, but readily soluble in alcohol and ether. According to M. Righini, iodoform possesses remarkable antiseptic and antispasmodic properties. He also attributes to it the power of retarding the progress of phthisis, when inhaled in ethereal solution.

IODOHYDRARGYRATE OF POTASSIUM. It has been found by chemists that different iodides will unite together in different proportions, forming compounds which are called by Berzelius double iodides. Bonsdorff, of Finland, and Dr. Hare, of this city, with greater reason, have viewed these combinations as a peculiar kind of salts, in which one of the iodides performs the part of an acid, the other of a base. The substance, the name of which is placed at the head of this article, is one of these compounds, and was presented to the notice of the profession, as a new remedy of remarkable powers, in February, 1834, by Dr. William Channing, of New York. (*Am. Journ. of Med. Sci.*, xiii. 388.) It consists of biniodide of mercury acting as an acid, and iodide of potassium as a base. But as these iodides combine in at least two proportions, it is necessary to indicate the particular combination employed by Dr. Channing.

In a difficult case of pectoral disease, in which the ordinary remedies had failed, Dr. Channing determined to make trial of one of the iodides of mercury. He selected the biniodide; and, in order to have it in the liquid form, it being insoluble in water, he dissolved it in a solution of iodide of potassium. He was struck with the chemical changes which the compound solution underwent; and, on pursuing his observations, he found that the two iodides really united by the intervention of the water; for, with the aid of

an operative chemist, he was enabled by evaporation to obtain them in union in the form of straw-coloured, needleform, deliquescent crystals. He next found, upon consulting the European authorities, that Bonsdorff, who had taken the lead in investigating similar compounds, had discovered the salt in 1826.

Dr. Channing analyzed the salt with which he experimented, and found that it consisted of one eq. of biniodide of mercury, and two of iodide of potassium. This he determined by ascertaining that an aqueous solution of a little more than eight grains of iodide of potassium would dissolve, and combine with, eleven grains of biniodide of mercury, without being liable to decomposition when largely diluted with water. The combination here indicated corresponds with one of the double iodides of mercury and potassium, described by Thenard. (*Traité de Chimie*, 6*ème ed.*, iii. 493.) The other is represented by this author as consisting of a single eq. of each iodide. When copiously diluted with water, every two eqs. of this iodide let fall one eq. of the mercurial iodide; thus evidently converting the salt into the medicinal double iodide. The same decomposition by the use of abundance of water is noticed by Dr. Channing. For remarks on these double iodides see a paper by Mr. Ambrose Smith, *Am. Journ. of Pharm.*, xii. 265.

Dr. Channing attributes to this preparation the effects of diffusing excitement, and equalizing the circulation. In the different cases in which he tried it, he thought he saw evidence of its favourable influence on the lungs, in allaying cough and improving expectoration; on the alimentary canal, in restoring the healthy secretions; on the kidneys, in reviving their activity; on the skin and cellular tissue, in cicatrizing superficial ulcerations; and on the absorbent and exhalant systems, in causing the disappearance of effused fluid. The principal diseases in which he found it useful were chronic bronchitis, hooping cough, tonsillitis, chronic gastro-enteritis, dyspepsia, ascites, anasarca, amenorrhœa, leucorrhœa, eruptions, and scrofula. In some cases of phthisis, it mitigated the symptoms, and appeared to prolong life. Dr. Hildreth, of Ohio, has tried this preparation, and reports favourably of its effects in ordinary dyspepsia unattended by organic disease, enlargement of the spleen, amenorrhœa, dysmenorrhœa, leucorrhœa, scrofulous affections, ascites, and general dropsy. (*Am. Journ. of Med. Sci.*, xxvi. 312.)

The average dose of the remedy may be stated at the twelfth of a grain three times a day; but in peculiar constitutions, not more than the forty-eighth, the ninety-sixth, or the two hundreth of a grain daily can be borne. For the convenience of physicians who may wish to make trial of the remedy, we give the following formula, deduced from the statements in Dr. Channing's paper.—Take of iodide of potassium three and a half grains; biniodide of mercury (red iodide), four and a half grains; distilled water a fluidounce. Dissolve first the iodide of potassium and then the biniodide of mercury in the water. The compound salt in this solution may be assumed to amount to eight grains, though there is a small excess of the iodide of potassium. Of this solution, from two to five drops, containing from the thirtieth to the twelfth of a grain, may be given three times a day. It may be administered in the compound syrup of sarsaparilla, which does not decompose it.

IONIDIUM MARCUCCI. This name has been conferred by Dr. Bancroft upon a South American plant, supposed to be the source of a medicine used with great asserted advantage in Maracaibo and elsewhere, in some of the horrible cutaneous affections, especially elephantiasis, to which the inhabitants of the tropical regions of this continent are subject. A specimen, however, received from Dr. Bancroft, was found by Sir W. Hooker to be identical with the *Ionidium parviflorum* of Ventinat. The medicine is called by the Indians *cuichunchulli*, and grows in the neighbourhood of Riobamba, a small town at the foot of the great mountain of Chimborazo. It is said to be diaphoretic, diuretic, occasionally sialagogue, and in large doses emetic and cathartic. The root is the part used. It is highly probable that other vegetable emeto-cathartics, having the same property of stimulating the secretions, would be found equally effectual. For an account of what is known in relation to this medicine, the reader is referred to a paper by Dr. Bancroft, republished in the *Am. Journ. of Pharm.*, iii. p. 125.

ISATIS TINCTORIA. *Woad. Pastel.* A biennial plant, indigenous in Europe, where it is also cultivated. The leaves have a fugitive pungent odour, and an acrid very durable taste, and have been used in scorbutic affections, jaundice, and other complaints; but the plant is valuable only as the source of a blue dye stuff, called *woad*, which has been long employed in Europe, though at present nearly superseded by indigo. The leaves are prepared by grinding them to a paste, which is made into balls, placed in heaps, and allowed to ferment. When the fermentation is at an end, the mass falls into a coarse powder, which is the dye stuff in question.

KALMIA LATIFOLIA. *Laurel. Mountain Laurel. Broad-leafed Laurel. Calico-bush.* This well-known evergreen inhabits all sections of the United States, but is particularly abundant on the sides of hills and mountains, which it adorns in summer with its elegant

flowers. It is from three to ten feet in height. The leaves are possessed of poisonous, narcotic properties, and have been used in medicine. They have been analyzed by Mr. Charles Bullock, of Philadelphia, and found to contain gum, tannic acid, resin, chlorophylle, fatty matter, a substance resembling mannite, an acrid principle, wax, extractive, albumen, yellow colouring matter, lignin, and salts of potassa, lime, and iron. (*Am. Journ. of Pharm.*, xx. 264.) They are said to prove fatal to sheep and some other animals, but are eaten with impunity by deer, goats, and partridges. Dr. Barton states in his "Collections," that the Indians sometimes use a decoction of the leaves to destroy themselves. It is said that death has been occasioned by eating the flesh of partridges and pheasants which have fed upon them during winter. Dr. N. Shoemaker published, in the *North American Medical and Surgical Journal*, two cases of poisoning which resulted from eating a pheasant, in the craw of which laurel leaves were found. The symptoms were nausea, temporary blindness, pain in the head, dyspnœa, pallid countenance, cold extremities, and a very feeble pulse, which in one case was for some time absent at the wrist, in the other beat only forty strokes in the minute. In both cases relief was afforded by vomiting, produced by a tablespoonful of flour of mustard mixed with warm water.

Dr. Barton was informed that the powdered leaves were employed by an empiric with success in certain states of fever; and Dr. Thomas, in an inaugural dissertation, published at Philadelphia, A. D. 1802, states that an obstinate case of diarrhœa was cured by a decoction, made by boiling an ounce of the leaves in eight ounces of water down to four ounces. Thirty drops were given six times a day; but this quantity produced vertigo, and the dose was afterwards repeated only four times daily. The leaves are said to have been used advantageously in syphilis. Externally applied, in the shape of ointment or decoction, they have been found useful in tinea capitis, psora, and other cutaneous affections; but caution is necessary in their application, as, according to Dr. Barton, nervous symptoms have resulted from the external use of the decoction. Dr. Bigelow has seen the recently powdered leaves given in doses of from ten to twenty grains, without perceptible effect.

It is probable that the other species of Kalmia, as *K. angustifolia*, or *sheep-laurel*, and *K. glauca*, or *swamp-laurel*, have properties identical with those of the *K. latifolia*. A decoction of the leaves of K. angustifolia is used by the negroes of North Carolina as a wash for ulcerative affections between the toes.

KOOSSO. The flowers of *Brayera anthelmintica* (Kunth), *Hagenia Abyssinica* (Lamarck), *Banckxia Abyssinica* (Bruce), a tree about twenty feet high, belonging to the family of Rosaceæ, growing on the table land of Abyssinia, at an elevation of not less than six or seven thousand feet. The Abyssinian name of the medicine has been variously spelled by European writers kosso, kousso, cusso, cosso, &c.; but that at the head of this article is deemed the most appropriate English title, as it indicates the proper pronunciation of the word. The flowers are small, greenish becoming purple, and arranged in repeatedly dichotomous clusters. The following is their botanic character. "*Calyx* with the tube bibracteolate at the base, turbinate; throat internally constricted by a membranous ring: the limb with two series of segments, each five in number, the outer much larger. *Petals* five, inserted in the throat of the calyx, small, linear. *Stamens* from 15 to 20, inserted with the petals. *Filaments* free, unequal. *Anthers* bilocular, dehiscing longitudinally. *Carpels* two at the bottom of the calyx, free, unilocular, containing one or two pendulous ovules. *Styles* terminal, exserted from the throat of the calyx, thickened upward. *Stigmas* subpeltate, dilated, crenate, oblong." The flowers are said to be dicœcious; though the male have well developed carpels. The petals are apt to be wanting in the dried flowers. They are brought from Abyssinia packed in boxes, the clusters being unbroken though compressed. The general colour of the mass is greenish-yellow. As the medicine in consequence of its high price is apt to be adulterated, it should if possible be procured in the unpowdered state, when the botanical characters of the flower will sufficiently test its genuineness.

The flowers have a fragrant balsamic odour; and their taste, little perceptible at first, becomes in a short time somewhat acrid and disagreeable. Analyzed by Wittstein, they were found to contain, in 100 parts, 1·44 of fatty matter and chlorophylle, 2·02 of wax, 6·25 of bitter acrid resin, 0·77 of tasteless resin, 1·08 of sugar, 7·22 of gum, 24·40 of tannic acid, 40·97 of lignin, 15·71 of ashes, with 0·14 parts loss.

Koosso is highly valued in Abyssinia as a vermifuge. Bruce speaks of it in his travels, and gives a figure of the plant. Dr. Brayer, a French physician practising in Constantinople, employed the medicine effectively, and published a treatise on it at Paris, so long ago as 1823. It was in his honour that Kunth adopted his generic title of the plant. Much attention has recently been attracted to this medicine; and trials made with it have proved that it has extraordinary efficacy in the destruction and expulsion of the tapeworm. Its effects when taken internally are not very striking. In the ordinary dose it sometimes produces heat of stomach, nausea, and even vomiting, and shows a tendency to act on the

bowels, though this effect is not always produced. It appears to operate exclusively as a poison to the worms; and has been found equally effectual in both kinds of tapeworm. The high price demanded for it has tended very much to restrict the use of the remedy; but, should the demand continue, it will no doubt be supplied at a reasonable cost, as it is brought by caravans from Abyssinia into Egypt; and the monopoly which was at first the cause of its expensiveness cannot be long maintained. The medicine is taken in the morning upon an empty stomach, a light meal having been made the preceding evening. A previous evacuation of the bowels is also recommended. The flowers are given in the form of powder, mixed with half a pint of warm water; the mixture being allowed to stand for fifteen minutes, then stirred up, and taken in two or three draughts at short intervals. The medicine may be preceded and followed by lemonade. The medium dose for an adult is half an ounce, which may be diminished one-third for a child of 12 years, one-half for one of 6, and two-thirds for one of 3. Should the medicine not operate on the bowels in three or four hours, a brisk cathartic should be administered. One dose is said to be sufficient to destroy the worm. Should the quantity mentioned not prove effectual, it may be increased to an ounce or more.

LABDANUM. *Ladanum.* A resinous substance obtained from various species of Cistus, especially *C. Creticus*, *C. ladaniferus*, and *C. laurifolius*, small evergreen shrubs, inhabiting the islands of the Grecian Archipelago, and the different countries bordering on the Mediterranean. Upon the leaves and branches of these shrubs a juice exudes, which is collected by means of an instrument resembling a rake, with leather thongs instead of teeth, which is drawn over the plant. The juice adheres to the pieces of leather, and is afterwards separated. It is said that labdanum was formerly collected by combing the beards of goats which had been browsing upon the leaves of the cistus; and Landerer states that it is at the present time gathered in the same way in Cyprus from sheep, whose fleeces become loaded with it while they are pasturing. (See *Pharm. Journ. and Trans.*, xi. 6.) It comes chiefly from the Grecian islands. Two varieties exist in commerce. The *purest labdanum* is in masses of various sizes, sometimes weighing several pounds, enclosed in bladders, dark-red almost black externally, grayish internally when first broken, of the consistence of a plaster, softening in the hand and becoming adhesive, of an agreeable balsamic odour like that of amber, and of a bitter, balsamic, somewhat acrid taste. It is very inflammable, burning with a clear flame. On exposure it becomes dry, porous, and brittle. Little of this variety is found in the markets. *Common labdanum* is in pieces of a contorted or spiral form, light, porous, blackish-gray, hard and brittle, not softening between the fingers, similar in odour and taste to the preceding variety, but less inflammable, and mixed with much sand and other earthy matter, which are obvious to the sight. Guibourt found in 100 parts of the labdanum in masses, 86 parts of resin with a little volatile oil, 7 of wax, 1 of watery extract, and 6 of earthy substances and hair. In the contorted variety, Pelletier found 20 per cent. of resin, 3·6 of gum with malate of lime, 0·6 of malic acid, 1·9 of wax, 1·9 of volatile oil including loss, and 72 of ferruginous sand.

Labdanum is a stimulant expectorant, and was formerly given in catarrhal and dysenteric affections. At present it is employed only in plasters, and seldom even for that purpose in the United States. It is sometimes used in fumigation.

LAC. A resinous substance obtained from several trees growing in the East Indies, particularly from *Croton lacciferum*, and two species of Ficus, *F. religiosa* and *F. Indica*. It is found in the form of a crust surrounding the twigs or extreme branches, and is generally supposed to be an exudation from the bark, owing to the puncture of an insect belonging to the genus *Coccus*, and denominated *C. Lacca*. By some it is thought to be an exudation from the bodies of the insects themselves, which collect in great numbers upon the twigs, and are embedded in the concreted juice, through which the young insects eat a passage and escape. Several varieties are known in commerce. The most common are *stick lac*, *seed lac*, and *shell lac*.

Stick lac is the resin as taken from the tree, still encrusting the small twigs around which it originally concreted. It is of a deep reddish-brown colour, of a shining fracture, translucent at the edges, inodorous, and of an astringent, slightly bitterish taste. Its external surface is perforated with numerous minute pores, as if made by a needle; and when broken it exhibits many oblong cells, often containing the dead insect. When chewed it colours the saliva beautifully red, and, when burnt, diffuses a strong agreeable odour. It is in great measure soluble in alcohol.

Seed lac consists of minute irregular fragments, broken from the twigs, and partially exhausted by water. It is of a light or dark-brown colour, inclining to red or yellow, feebly shining, almost tasteless, and capable of imparting to water less colour than the stick lac, sometimes scarcely colouring it at all. It is occasionally mixed with small fragments of the twigs.

Shell lac is prepared by melting the *stick* or *seed lac* previously deprived of its soluble

colouring matter, straining it, and pouring it upon a flat smooth surface to harden. It is in thin fragments of various sizes, from half a line to a line thick, often somewhat curved, of a lighter or darker brown colour inclining more or less to red or yellow, shining, more or less transparent, hard and brittle, inodorous and insipid, insoluble in water, but easily and almost entirely soluble in alcohol, especially with the aid of heat.

A variety of lac is mentioned by writers in the form of cakes, called *cake* or *lump lac* (*lacca in placentis*); but this is at present rare in commerce.

According to John, lac consists of resin, colouring matter, a peculiar principle insoluble in alcohol, ether, or water, called *laccin*, a little wax, and various saline matters in small proportion. The resin, according to Unverdorben, consists of several distinct resinous principles differing in their solubility in alcohol and ether. The laccin is nearly or quite wanting in the *shell lac*, which also contains scarcely any of the colouring principle. Mr. Hatchett found in *stick lac* 68 per cent. of resin and 10 of colouring matter; in *seed lac* 88·5 per cent. of resin, and 2·5 of colouring matter: in *shell lac* 90·9 per cent. of resin and 0·5 of colouring matter. The other constituents, according to this chemist, are wax and gluten, besides foreign matters.

Lac in its crude state is slightly astringent, and was formerly used in medicine. At present it is not employed. Shell lac is wholly inert. Stick lac and seed lac are used on account of the colouring principle which they contain. Shell lac, as well as the other varieties deprived of their colouring matter, is applied to numerous purposes in the arts. It is the chief constituent of sealing wax. The best *red sealing wax* is made by melting together, with a very gentle heat, 48 parts of shell lac, 19 of Venice turpentine, and 1 of balsam of Peru, and mixing with the melted mass 32 parts of finely powdered cinnabar. But common resin is often substituted in part for the lac, and a mixture of red lead and chalk for the cinnabar. The best *black sealing wax* consists of 60 parts of lac, 10 of turpentine, and 30 of levigated bone black: the best *yellow sealing wax*, of 60 parts of lac, 12 of turpentine, and 24 of chromate of lead. (*Berzelius.*) Lac is also used as a varnish, and forms an excellent cement for broken porcelain and earthenware. It has been highly recommended as an adhesive material for the dressing of wounds, ulcers, &c. It is prepared for use by dissolving, with the aid of a gentle heat, in alcohol contained in a glass bottle, sufficient lac to give it a gelatinous consistence, and then closing the bottle. It is used by simply spreading it on the bandages.

LACTATE OF IRON. *Ferri Lactas. Lactate of Protoxide of Iron.* MM. Gélis and Conté introduced this preparation to the notice of the profession. As it was admitted by many physiologists, that lactic acid was the cause of the acidity of the gastric juice, and the fact seemed to be proved by MM. Bernard and Barreswil, MM. Gélis and Conté concluded that the ordinary ferruginous preparations, when efficacious, are dissolved by this acid in the stomach, and were led to suppose that lactate of iron, ready formed, might prove a valuable remedy. Their anticipations appear to have been realized; for several French physicians of note, among whom were MM. Fouquier, Bally, and Bouillaud, the committee appointed on their memoir by the French Academy of Medicine, reported favourably in relation to its therapeutic powers.

M. Louradour recommends the following process for obtaining lactate of iron. Ferment whey by keeping it at a temperature between 70° and 80°, whereby it becomes charged with a considerable quantity of lactic acid. Evaporate the liquor to a third of its bulk, decant and filter, and then saturate with milk of lime. This converts the lactic acid into lactate of lime, remaining in solution, and throws down a precipitate, consisting principally of phosphate of lime. The liquor is filtered again, and precipitated by oxalic acid, which throws down the lime as oxalate of lime, and sets free the lactic acid. By a new filtration a solution of lactic acid is obtained, containing lactin (sugar of milk) and certain salts, but pure enough for conversion into lactate of iron. For this purpose iron filings are digested with it on a sand-bath at a gentle heat. At the end of six or seven hours, the liquor is made to boil; after which it is filtered, concentrated, and allowed to cool and crystallize. The lactin and foreign salts remain in the mother-water. The crystals are drained in a funnel, washed with alcohol, dried rapidly, and then transferred to a bottle which must be well stopped. A better process for preparing lactate of lime, preparatory to its conversion into lactic acid and lactate of iron, is that of M. Gobley, as follows.—Add to 2 pints of skim-milk, diluted with twice its bulk of water, and contained in an earthen pan, 64 drachms of powdered lactin, and 51 drachms of powdered chalk. Allow the whole to ferment for eleven or twelve days, at a temperature of from 80° to 90°, supplying water as it evaporates. Transfer the liquor to a capsule, heat it gradually to boiling, and stir it constantly. Boil for a quarter of an hour to coagulate casein, allow the insoluble matters to subside, and strain the liquid through flannel. The clear liquid is a solution of lactate of lime. In this process the casein of the milk, acting as a ferment, converts not only the lactin of the milk, but the lactin added, into lactic

acid; a result which would not take place were it not for the presence of the chalk, which saturates the lactic acid as it is formed, and prevents it from uniting with the casein, whereby the power of the latter as a ferment would be destroyed. (*Journ. de Pharm.*, 3e *sér.*, vi. 54.) Lactate of lime may be converted into lactate of iron more expeditiously than by the method of M. Louradour by the following process of M. Lepage. Dissolve 100 parts of lactate of lime, obtained by M. Gobley's process, in 500 parts of boiling water; and 68 parts of pure crystallized sulphate of protoxide of iron in 500 parts of cold distilled water. Mix the filtered solutions in a matrass, acidulate slightly with lactic acid, and heat in a water bath, stirring frequently until the double decomposition is completed. Then filter to separate the sulphate of lime, and evaporate rapidly to one-half, either in an iron vessel, or in a porcelain capsule containing a few turnings of iron. Filter again, and set aside to crystallize; and, having washed the crystals in a funnel with a little alcohol, dry them on bibulous paper. (*Journ. de Pharm.*, 3e *sér.*, ix. 272.) In relation to the precautions to be observed in preparing this lactate, so as to prevent the partial sesquioxidation of the iron, see the paper of M. C. J. Thirault in the *Journ. de Pharm.*, copied into the *Am. Journ. of Pharm.* for Nov., 1853, p. 556.

Lactate of iron is in white crystalline plates, undergoing little change in the air. When in the form of a yellowish or greenish-white powder it is impure. It is but sparingly soluble in water, requiring forty parts of boiling water to dissolve it. It has an acid reaction, and possesses a mild ferruginous taste. The aqueous solution quickly becomes yellow, in consequence of the iron passing to a higher state of oxidation. M. Louradour has observed several samples of this lactate, variously adulterated; as with effloresced sulphate of iron, starch, and lactin; the sophistication being concealed by the sale of the salt in powder. These impurities may be detected by appropriate reagents; but M. Louradour recommends, as a simpler way of avoiding them, the rejection of the salt when not in crystalline plates.

Medical Properties. Lactate of iron has the general medical properties of the ferruginous preparations. It has a marked effect in increasing the appetite. The disease in which it was principally tried in Paris was chlorosis, with or without amenorrhœa; and in this disease, Andral, Fouquier, Bouillaud, and others obtained very favourable results. The dose is one or two grains, repeated at intervals and gradually increased. As much as 12 or even 20 grains may be given in the course of the day. It may be administered in lozenge, pill, or syrup. The *lozenge* may be made of one grain of the lactate to twelve of sugar; and the *pill*, of one grain of the salt, with an equal weight of some inert powder free from astringent matter, and sufficient honey. The following is the formula for a *syrup* proposed by M. Cap, expressed in the nearest weights and measures used in this country. Take of lactate of iron *a drachm;* white sugar *twelve ounces and a half;* boiling distilled water *six fluidounces and a half.* Rub the salt to powder with half an ounce of the sugar; and dissolve the mixture quickly in the boiling water. Pour the solution into a matrass placed on a sand-bath, and add to it the rest of the sugar in small pieces. When the sugar is dissolved, filter the syrup, and, as soon as it is cold, transfer it to bottles which must be well stopped. This syrup has a very light amber colour, and contains about four grains of the salt to the fluidounce. The dose is from two to four fluidrachms. Bread, called *chalybeate bread*, containing lactate of iron in the proportion of about a grain to the ounce, has been used with advantage by chlorotic patients in one of the hospitals of Paris. The bread is not injured in taste or quality. Dr. Brainard, of Chicago, has treated, with success, a large erectile tumour of the orbit, by infiltrating it by injection with a fluidrachm of a solution of lactate of iron, containing eight grains of the salt. (See *Ranking's Abstract*, xviii. 253.)

LACTIC ACID. *Acidum Lacticum.* This acid was discovered by Scheele. It is interesting as having been found in a number of the secretions, including the healthy gastric juice, in which its presence has been incontestably proved to exist by Bernard and Barreswil. It is a product of the viscous or lactic fermentation of rice-water, and of the juices of the beet, turnip, and carrot. Indeed, it is formed whenever sugar, in solution, of whatever kind, is placed in contact with an alkaline or earthy carbonate, in presence of a ferment, as, for example, the casein of milk. (*Pelouze.*) It may be conveniently obtained from the solution of impure lactic acid, mentioned in the last article, by concentrating it to a syrupy consistence, and treating it with alcohol, which dissolves the acid and precipitates the lactin and foreign salts. The solution is filtered, and the lactic acid is obtained pure by distilling off the alcohol. It is a colourless syrupy liquid, having a very sour taste, and the sp. gr. 1·215. When heated to 480°, the greater part of it is converted into a new body called concrete lactic acid, or *lactide*. Lactic acid coagulates albumen, and dissolves a large quantity of freshly precipitated phosphate of lime, a property which, doubtless, renders it of importance in the animal economy. The formula of the hydrated acid is $C_6H_5O_5+HO$. The acid obtained from the fluids of the flesh of animals by Liebig, was found to have the same per centage composition as lactic acid, but still to differ from it

in the proportion of water in the zinc and lime salts. Dr. W. Heintz considers the acid from flesh to be isomeric with lactic acid, and proposes to call it *paralactic acid.* (*Chem. Gaz.*, Mar. 1, 1849.) The lactic acid of the stomach is ordinary lactic acid. (Heintz, *Ibid.*, Nov. 1, 1849.)

Lactic acid was proposed by Magendie on theoretical grounds as a remedy in certain forms of dyspepsia, and for the removal of phosphatic deposits in the urine. It is most conveniently given in solution sweetened with sugar, prepared like lemonade. From one to three drachms may be taken in the course of the day.

LAKES. These are compounds of vegetable or animal colouring principles with alumina or other metallic oxides, and are usually obtained by adding alum, or perchloride of tin, to the solution of the colouring matter in water, and precipitating by means of an alkali. The alumina or oxide of tin unites with the colouring matter at the moment of separation, and forms an insoluble compound. Lakes are obtained in this way from cochineal, madder, Brazil wood, seed lac, French berries, &c. They are used in painting.

LEDUM PALUSTRE. *Marsh Tea. Rosmarinus sylvestris.* A small evergreen shrub, growing in swamps and other wet places, in the northern parts of Europe, Asia, and America, and in the mountainous regions of more southern latitudes. The leaves have a balsamic odour, and an aromatic, camphorous, bitter taste; and contain, among other ingredients, volatile oil and tannin. They are thought to possess narcotic properties, and have been employed in exanthematous diseases to allay irritation, in hooping cough, in dysentery, and in various cutaneous affections, particularly leprosy and scabies. In complaints of the skin, they are used both internally and externally in the form of decoction. When placed among clothes, they are said to prevent the attacks of moths. In Germany they are sometimes substituted for hops in the preparation of beer. *Ledum latifolium*, or *Labrador tea*, which is a larger plant than the preceding, is a native of North America, growing in damp places in Canada and the northern parts of the United States. The leaves have an agreeable odour and taste, and are esteemed pectoral and tonic. They are said to have been used as a substitute for tea during the war of independence.

LEEK. *Porrum.* The bulb of *Allium Porrum.* The leek is a biennial bulbous plant, growing wild in Switzerland, and cultivated in the gardens of Europe and this country for culinary purposes. All parts of it have an offensive pungent odour, and an acrid taste, dependent on an essential oil, which is in a great measure dissipated by decoction, and may be obtained separate by distillation. The bulb, which is the medicinal portion, consists of concentric layers, like the onion, which it resembles in medical properties, though somewhat milder. It is gently stimulant, with a peculiar direction to the kidneys. The expressed juice may be given in the dose of a fluidrachm, mixed with syrup. This species of Allium is not used medicinally in the United States.

LEPTANDRA VIRGINICA. Nuttall. *Veronica Virginica.* Linn. *Culver's Physic.* This is an indigenous perennial plant, with an herbaceous stem three or four feet high, furnished with leaves in whorls, and terminating in a long spike of white flowers. A variety was seen by Pursh with purple flowers. This was described and figured as a distinct species by Rafinesque, under the title of *L. purpurea.* The plant grows throughout the United States, affecting particularly calcareous hills and sunny exposures, and flowering in August. The root, which is the part used, is bitter and nauseous, and yields its active properties to boiling water. When recent it is said to act violently as a cathartic, and sometimes as an emetic. In the dried state it is more uncertain. The dose of the powder is from twenty grains to a drachm. It was formerly recognised in the U. S. Pharmacopœia, but was omitted in the edition of 1840.

LIATRIS SPICATA. *Gay-feather. Button Snakeroot.* An indigenous perennial plant, growing in natural meadows and moist grounds throughout the Middle and Southern States. It has a tuberous root, and an erect annual stem, which terminates in a spike of beautiful, purple, compound flowers, which appear in August. The root is said by Schoepf to have a terebinthinate odour, and a warm, bitterish, terebinthinate taste; to be possessed of diuretic properties; and to be useful in gonorrhœa and sorethroat, being employed internally in the shape of decoction in the former complaint, and as a gargle in the latter. Pursh informs us that *L. scariosa* and *L. squarrosa* are known in Virginia, Kentucky, and the Carolinas, by the name of *rattlesnake's master;* and that their roots are employed to cure the bite of the rattlesnake, being bruised and applied directly to the wound, while their decoction in milk is taken internally. According to Dr. William P. C. Barton, all the tuberous rooted species of Liatris are active plants, and appear to be diuretic.

LIGUSTICUM LEVISTICUM. *Lovage.* An umbelliferous plant, growing wild in the South of Europe, and cultivated in gardens. The whole plant has a strong, sweetish,

aromatic odour, and a warm pungent taste. When wounded it emits a yellow opaque juice, which concretes into a brownish resinous substance, not unlike opopanax. The roots, stem, leaves, and seeds have all been employed; but the last have the aromatic properties of the plant in the highest degree. They are small, ovate oblong, somewhat flattened, curved, strongly ribbed, and of a yellowish-brown colour. The medical properties of lovage are closely analogous to those of angelica. It is a stimulant aromatic, and has been employed as a carminative, diaphoretic, and emmenagogue. The best form for administration is that of infusion.

LIGUSTRUM VULGARE. *Privet.* A shrub from four to ten feet in height, growing wild both in Europe and the United States, usually in hedges and by the roadside. The *leaves* which have an astringent, bitter taste, and the *flowers*, which are small, snow-white, and of an agreeable odour, have been used, in the form of decoction, in sorethroat, and aphthous and scorbutic ulceration of the mouth. The *berries* are black, have a sweetish, bitter taste, and are said to possess purgative properties, and to colour the urine brown. They are sometimes used for dyeing. The bark was analyzed by M. G. Potex, who found a peculiar substance which he denominated *ligustrin*, besides mannite, sugar, muco-saccharine matter, starch, chlorophylle, bitter extractive, bitter resin, tannin, albumen, and salts. (*Am. Journ. of Pharm.*, xii. 347.)

LILIUM CANDIDUM. *Common White Lily.* This well-known plant is a native of Syria and Asia Minor, but has been long cultivated in gardens. The bulb, which consists of imbricated fleshy scales, is without odour, but has a peculiar, disagreeable, somewhat bitter, and mucilaginous taste. It contains much mucilage, and a small proportion of an acrid principle, which is dissipated or destroyed by roasting or boiling. In the recent state it is said to have been employed with advantage in dropsy. Boiled with water or milk it forms a good emollient cataplasm, more used in popular than in regular practice. The flowers have an agreeable odour, which they impart to oil or lard; and an ointment or liniment is sometimes prepared from them, and used as a soothing application in external inflammations.

LIQUIDAMBAR STYRACIFLUA. *Sweet-gum.* An indigenous tree, growing in different parts of the United States from New England to Louisiana, and flourishing also in Mexico, where, as well as in our Southern States, it sometimes attains a great magnitude. In warm latitudes a balsamic juice flows from its trunk when wounded. This has attracted some attention in Europe, where it is known by the name of *liquidamber*, or *copalm balsam*, and is sometimes, though erroneously, called *liquid storax*. It is not yielded by the trees which grow in the Middle States, and is obtained from Mexico and Louisiana. It is a liquid of the consistence of thin honey, more or less transparent, of a yellowish colour, of a peculiar, agreeable, balsamic odour, and a bitter, warm, and acrid taste. By cold it becomes thicker and less transparent. It concretes also by time, assuming a darker colour. According to M. Bonastre, it contains a colourless volatile oil, a semi-concrete substance which rises in distillation and is separated from the water by ether, a minute proportion of benzoic acid, a yellow colouring substance, an oleo-resin, and a peculiar principle, insoluble in water and cold alcohol, for which M. Bonastre proposes the name of *styracine*. The proportion of benzoic acid is greatly increased by time. Mr. Hodgson obtained from a specimen which he examined 4·2 per cent. (*Journ. of the Phil. Col. of Pharm.*, vi. 190.)

Another product is said to be obtained from the same tree by boiling the young branches in water, and skimming off the fluid which rises to the surface. It is of a thicker consistence and darker colour than the preceding, is nearly opaque, and abounds in impurities. This also has been confounded with liquid storax, which it resembles in properties, though derived from a different source.

Liquidamber may be employed for the same purpose as storax, but is very seldom used, and is almost unknown in the shops of the United States.

Liquidambar Altingia is said to exude a balsam in the Tennasserim Provinces of India, bearing some resemblance to liquid storax. (See *Pharm. Journ. and Trans.*, viii. 243.)

LITHIA. *Protoxide of Lithium.* This is the protoxide of a metallic radical called lithium, and ranks with potassa and soda as one of the fixed alkalies. It is a constituent of several minerals (petalite, spodumene, lepidolite, &c.), and has been found in a number of the mineral waters of Europe, principally in the state of carbonate or bicarbonate. *Carbonate of lithia* in solution in water has been proposed by Mr. A. Ure as a solvent for uric acid calculi, injected into the bladder. By experiments made out of the body, conducted at the heat of the blood, it was found that a solution of this salt was a better solvent of uric acid than either borax or the carbonates of potassa and soda. It is a white powder, soluble in 100 parts of cold water, but insoluble in alcohol. Its effects

when exhibited by the stomach have not been tried; but it is supposed that it might prove useful in the uric acid diathesis. According to Aschenbrenner it may be given in doses of from five to ten grains daily.

LITHOSPERMUM OFFICINALE. *Gromwell. Milium Solis.* A European perennial, the seeds of which are ovate, of a grayish-white or pearl colour, shining, rather larger than millet seeds, and of a stony hardness, from which the generic name of the plant originated. From an opinion formerly prevalent, that nature indicates remedies adapted to certain diseases by some resemblance between the remedy and the character of the complaint or of the part affected, the seeds of this plant were applied to the treatment of calculous disorders; and they retained their ground in the estimation of physicians as a diuretic, useful in complaints of the urinary passages, long after the fanciful notion in which their use originated had been abandoned. But they are at present considered nearly inert, and are not employed.

LONICERA CAPRIFOLIUM. *Honeysuckle.* This ornament of our gardens is a native of the South of Europe. Its sweet-scented flowers are sometimes used in perfumery; and a syrup prepared from them, has been given in asthma and other pectoral affections. The expressed juice of the plant has been recommended as a remedy for the stings of bees, being rubbed directly on the injured spot. The fruit of all the species of Lonicera is said to be emetic and cathartic. (*Mérat et De Lens, Dict. de Mat. Med.*, iv. 144.)

LYCOPODIUM CLAVATUM. *Club-moss.* The capsules of this moss, and of others belonging to the same genus, contain a fine dust or powder, which is collected in Switzerland and Germany, and used in the shops of Europe under the name of *lycopodium*, or *vegetable sulphur*. This powder is considered by some as the pollen of the plant, by others as the seed. It is extremely fine, very light, of a delicate yellow colour, inodorous and tasteless, and exceedingly inflammable, so much so that it takes fire like gunpowder when thrown upon a burning body. It is said to be often adulterated with the pollen of the pines and firs, and sometimes with talc and starch. In medicine, it is used as an absorbent application to excoriated surfaces, especially those which occur in the folds of the skin in infants. In pharmacy, it answers the purpose of facilitating the rolling of the pilular mass, and of preventing the adhesion of the pills when formed. It is not much used in this country. The moss itself has been esteemed diuretic, antispasmodic, &c.; and has been employed in the form of decoction, in rheumatism, epilepsy, and complaints of the lungs and kidneys; but it has fallen into discredit.

LYTHRUM SALICARIA. *Loosestrife. Purple Willow-herb.* This is an elegant perennial plant, two or three feet high, with an erect, quadrangular, hexagonal, downy, herbaceous stem, bearing opposite, ternate, sessile, lanceolate leaves, cordate at the base, and downy on the under surface and at the margin. The flowers are axillary, forming a leafy verticillate spike. The calyx is red, with unequal segments, the petals purple and undulate, the fruit a small elliptical capsule. The plant grows wild in all parts of Europe, and is found in New England and Canada. It prefers meadows, swamps, and the banks of streams, which it adorns in July and August with its showy purple flowers. The whole herbaceous part is medicinal, and is dried for use. In this state it is inodorous, and has an herbaceous somewhat astringent taste. It renders boiling water very mucilaginous, and its decoction is blackened by the sulphate of iron. Loosestrife is demulcent and astringent, and may be advantageously given in diarrhœa and chronic dysentery, after due preparation by evacuating treatment. It has long been used in Ireland in these complaints, and is said to be a popular remedy in Sweden. The dose of the powdered herb is about a drachm two or three times a day. A decoction of the root, prepared by boiling an ounce in a pint of water, may be given in the dose of two fluidounces.

MALAMBO or MATIAS BARK. A bark received from S. America by Dr. Alexander Ure, under the name of *matias bark*, was found to have the characters of the *malambo bark*, which is held in high esteem in New Granada where it is produced, and has been long known to the French pharmacologists. It is described by Dr. Ure as being three or four lines thick, brittle though somewhat fibrous, of a brown colour, and covered with an ash-coloured tuberculous epidermis. It has an aromatic odour, and a bitter pungent taste, and yields these properties to water and alcohol. Its active ingredients appear to be a volatile oil, and a bitter extractive matter. According to Dr. Mackay, it has been used successfully in intermittents, convalescence from continued fever, hemicrania, dyspepsia, and other cases in which tonic remedies are useful, and also as an adjuvant to diuretics. It is probably nothing more than an aromatic tonic. Dr. Ure has often administered it with good effect as a substitute for Peruvian bark. (*Pharm. Journ. and Trans.*, iii. 169.)

MANDRAGORA OFFICINALIS. *Atropa Mandragora.* Linn. *Mandrake. Mandragora.* A perennial European plant, with spindle-shaped root, which is often forked beneath, and

is therefore compared, in shape, to the human figure. In former times this root was supposed to possess magical virtues, and was used as an amulet to promote fecundity, &c.; and the superstition is still cherished by the vulgar in some parts of Europe. The plant is a poisonous narcotic, somewhat similar in its properties to belladonna, to which it is botanically allied. It was much used by the ancients with a view to its narcotic effects; and the root has been recommended by some eminent modern physicians, as an external application to scrofulous, scirrhous, and syphilitic tumours. It is said to have been used by the ancients as an anæsthetic agent before surgical operations. (*Journ. de Pharm. et de Chim.* xv. 290.) It is unknown as a remedy in the United States.

MANGANESE. *Manganesium.* This metal and its compounds with oxygen (three regular oxides and two acids) have been already described. See *Manganesii Oxidum.* Several of its combinations have been proposed as medicines, and the therapeutic trials, thus far made with its preparations, place them alongside of those of iron as tonic and anti-anemic remedies. It will be recollected that manganese as well as iron is always present, in minute proportion, in healthy blood; and it is probable that the former is as necessary to its normal constitution as the latter. According to an analysis by M. Burin-Dubuisson, the amount of the manganese in the blood corpuscles is about one-twentieth that of the iron. Besides, manganese has been detected in the gastric juice, the bile, the brain, the hair, and in healthy pus. It is stated as an advantage of the preparations of manganese, that they may be prescribed in conjunction with tannic acid and the various astringent medicines, which are all incompatible with the preparations of iron. Of the oxides of manganese, the *protoxide* alone is strongly salifiable; and this is the oxide present in the ordinary salts of the metal. It may be obtained by precipitation as a white hydrate from any of the soluble salts of manganese by the addition of a caustic alkali. This, according to M. Hannon, is a good medicinal preparation; but a strong objection to it is that it rapidly absorbs oxygen, and passes to the state of the brown hydrated sesquioxide. The officinal deutoxide (native black oxide) is described at *page* 463, where its medical properties are also noticed. This oxide is the source, directly or indirectly, of all the preparations of manganese.

Sulphate of Manganese. This salt may be prepared by heating the native black oxide with concentrated sulphuric acid. Oxygen is evolved, and the sulphate of the protoxide is formed. The product, upon being exhausted by water, furnishes a solution which must be heated to nearly the boiling point, and treated with carbonate of manganese, added by small portions at a time, which will precipitate any iron present as a carbonate, and change the colour of the liquid from a dark-red to a pale-rose tint. The liquid is then filtered, evaporated to the consistence of a thin syrup, and set aside to crystallize. Sulphate of manganese is in the form of pale rose-coloured crystals, which contain different proportions of water of crystallization, according to the temperature at which they are produced. Its taste is astringent and bitterish. It is very soluble in water, but insoluble in alcohol. This salt, if carelessly prepared, is apt to contain copper and arsenic, as well as iron. As it is the source of nearly all the preparations of manganese, it is of importance that it should be pure. Hence, the sulphate, as first obtained, should be calcined at a low red heat at least twice, to render the contaminating metals insoluble, and then tested in solution, to be sure of its purity. According to M. A. Gorgeu, copper and iron, as well as nickel and cobalt, are completely precipitated by sulphuret of manganese. In applying this reagent, the impure solution is shaken for about a quarter of an hour with the sulphuret, and then boiled for a few minutes. (*Chem. Gaz.*, July 1, 1853, p. 249.) C. G. Gmelin found sulphate of manganese to produce an extraordinary secretion of bile when given to the inferior animals, and its effects as a cholagogue have been observed in man. According to the late Dr. Thomas Thomson, of Glasgow, it resembles sulphate of soda both in taste and effect. The dose as a purgative is one or two drachms; as an alterative, from five grains to a scruple.

Iodide of Manganese. This iodide may be administered in syrup or in pill. Prof. Procter has proposed the following formula for the *syrup.* Dissolve *sixteen drachms* of sulphate of manganese, and *nineteen drachms* of iodide of potassium, separately, in *three fluidounces* of water, each portion of water being previously sweetened with *two drachms* of syrup. Mix the solutions in a glass stoppered bottle, and, when the crystals of sulphate of potassa have ceased to precipitate, throw the liquor on a strainer of fine muslin, and allow it to filter into a pint bottle containing *twelve ounces* of powdered sugar. When the solution has ceased to pass, wash the filter with a little sweetened water, and add sufficient of that liquid to make the whole measure *a pint.* Lastly, agitate the liquid until the sugar is dissolved. Prof. Procter states that this syrup contains about a drachm of iodide of manganese in each fluidounce, and corresponds in strength to the officinal solution of iodide of iron. The small proportion of sulphate of potassa which remains dissolved in the syrup, does not interfere with its medicinal efficacy. The dose is from ten to thirty drops, re-

peated several times a day. (*Am. Journ. of Pharm.*, Oct. 1850.) M. Hannon makes the *pill of iodide of manganese* by double decomposition between equal weights of iodide of potassium and crystallized sulphate of manganese. The salts are perfectly dried, accurately mixed in powder, and then rubbed up with honey, so as to reduce the whole to a pilular mass, which may be divided into four-grain pills. Assuming that the honey added compensates the loss of water in drying, each pill will consist of about two grains of iodide of manganese, one of sulphate of potassa, and one of honey and of sulphate of manganese in excess. The dose is one pill daily, gradually increased to six. According to M. Hannon, iodide of manganese is particularly useful in the anemia attendant on scrofula, phthisis, and cancer, and in syphilitic cachexy. Given in conjunction with cinchona it rapidly removes the enlargement of the spleen, which so often follows protracted fevers.

Carbonate of Manganese. This salt may be obtained by the following formula, which is that of M. Hannon, accommodated to the weights and measures of the U. S. Pharmacopœia. Dissolve *seventeen ounces* of crystallized sulphate of manganese and *nineteen ounces* of carbonate of soda, separately, in two pints of water, *a fluidounce* of syrup having been previously added to each pint, and, having mixed the solutions in a well stopped bottle, allow the precipitate to subside. Decant the supernatant liquid, wash the precipitate with sweetened water, allow it to drain from a cloth saturated with syrup, express, mix with *ten ounces* of honey, and evaporate rapidly to form a pilular mass, which is to be divided in four-grain pills. By a double decomposition between the sulphate of manganese and carbonate of soda, carbonate of manganese is precipitated, and sulphate of soda remains in solution. The sulphate is washed away, and the carbonate is brought to a pilular consistence with honey, which, together with the syrup, prevents the protoxide of manganese in the pill from rising to a higher stage of oxidation. The dose is from two to ten pills daily. Carbonate of manganese was tried by M. Hannon as a medicine on himself. After its use for fifteen days he found his appetite improved, and his pulse increased in force; and he experienced a feeling of sanguineous plethora. He afterwards exhibited the remedy in several anemic cases with the effect of exciting the functions to a more healthy action, increasing the strength, and improving the blood.

Phosphate, tartrate, and *malate of manganese* have also been proposed by M. Hannon as useful remedies. The phosphate is prepared by double decomposition between sulphate of manganese and phosphate of soda.

Hypermanganate of Potassa. Permanganate of Potassa. This salt may be formed by mixing equal parts of very finely powdered deutoxide of manganese and chlorate of potassa with rather more than one part of hydrate of potassa, dissolved in a little water, and exposing the whole, after evaporation to dryness, to a temperature just short of redness. The mass is treated with hot water, the insoluble oxide separated by decantation, and the deep-purple liquid concentrated by heat, until crystals begin to form upon its surface, when it is left to cool and crystallize. The crystals have a dark-purple colour, and are soluble in sixteen parts of water. The salt is represented by the formula KO,Mn_2O_7. Hypermanganate of potassa has been used successfully by Mr. Sampson, of London, in diabetes. The dose is three grains, three times a day, given in three or four tablespoonfuls of water, and gradually increased. (*Pharm. Journ. and Trans.*, July 1, 1853, p. 18.)

Ferro-manganic Preparations. M. Hannon conceives that manganese is peculiarly suited to the treatment of anemic cases in which iron has failed, or acts very slowly. But, instead of passing at once from the use of iron to that of manganese, he prefers to give intermediately a mixture of the two metals. For this purpose he recommends the following formula. Take of crystallized sulphate of iron *six drachms and a half;* crystallized sulphate of manganese *two drachms;* carbonate of soda *nine drachms;* honey *five drachms.* Rub together, and with syrup make a mass, to be divided into four grain pills. In this pill both the metals are present as carbonates; and as the sulphate of soda is not washed away, it contains that salt also. The dose is from two to ten pills daily. See the paper of M. Hannon (*Journ. de Pharm.*, 3*e sér.*, xvi. 41 and 189; also a note of the favourable results obtained by M. Pétrequin, of Lyons, *Ibid.*, xvi. 381). Further experience has confirmed the favourable opinion of M. Pétrequin in relation to the therapeutic value of the ferro-manganic preparations. A number of formulæ have been devised by M. Burin-Dubuisson, of Lyons, for making them, containing the metals variously combined; but the most important of them is the *syrup of iodide of iron and manganese*, for the preparation of which we prefer the following formula of Prof. Procter. Take of iodide of potassium 1000 grains; sulphate of protoxide of iron 630; sulphate of protoxide of manganese 210; iron filings 100; sugar, in coarse powder, 4800. Powder the iodide and sulphates separately, and, having mixed them with the filings, add half a fluidounce of distilled water, and triturate to a uniform paste. Then add another half fluidounce of distilled water to the paste, and triturate again; and, after an interval of fifteen minutes, add a third half fluidounce, and mix. Next transfer the

magma of salts to a moistened filter, supported on a funnel, and allow them to drain into a bottle, holding a little more than twelve fluidounces, and containing the sugar. After they have drained, add boiled cold water by small portions at a time, until the solution of the iodides has been displaced and washed from the crystalline magma of sulphate of potassa. Finally, add sufficient boiled cold water to make the whole measure *twelve fluidounces*. The object of the iron is to prevent the liberation of iodine. This syrup has a very pale straw colour. It necessarily contains a little sulphate of potassa, which does not injure it as a therapeutic agent. If the salts have not been all decomposed during their reaction, it will be greenish. Each fluidounce contains fifty grains of the mixed iodides, in the proportion of three parts of iodide of iron to one of iodide of manganese. The dose is from ten drops to half a fluidrachm. (*Am. Journ. of Pharm.*, May, 1853, p. 198.) This syrup is considered by M. Pétrequin to be particularly suited to the treatment of anæmia resulting from obstinate intermittent fevers, from prolonged suppuration, and from scrofulous, syphilitic, and cancerous affections.

Dr. T. S. Speer, of Cheltenham, in imitation of the practice of M. Hannon and M. Pétrequin, has employed the combined carbonates of iron and manganese with excellent effects: but, instead of using the carbonates in pill, protected by honey and syrup, as M. Hannon has done, he prefers a saccharine carbonate of the two metals, in imitation of the London saccharine carbonate of iron, made by the following formula. Dissolve *three ounces and one drachm* of sulphate of iron, *one ounce and one scruple* of sulphate of manganese, and *five ounces* of carbonate of soda, each, in *thirty Imperial fluidounces* of water, and thoroughly mix the solutions. Collect the precipitated carbonates on a cloth filter, and wash them immediately with cold water, to separate the sulphate of soda. Then press out as much water as possible, and, without delay, triturate the pulp with *two and a half ounces* of finely powdered sugar. Lastly, dry the mixture at a temperature not exceeding 120° F. The *saccharine carbonate of iron and manganese*, as thus prepared, is a reddish-brown powder, devoid of all taste, except that imparted by the sugar. The dose is five grains, gradually increased to a scruple, three times a day, given with the meals, or immediately after them. (See *Am. Journ. of Pharm.*, March, 1854, p. 127, from the *Med. Times and Gaz.*)

MEAT BISCUIT. This alimentary substance, containing much nutriment in a small bulk, is the invention of Mr. Gail Borden, jun., of Texas. It is made by mixing a concentrated fluid extract of flesh, strained through wire-cloth, and freed from fat, with good wheat flour or other meal, and baking the dough into a biscuit, which must be preserved, in mass or coarse powder, free from moisture, in gutta percha bags, or air-tight casks or cases. To make the dough, about two parts of the extract are mixed with three of the flour; and about twenty per cent. is lost in baking. The extract contains the soluble ingredients of the flesh, not coagulable by heat; namely, gelatin, kreatin, kreatinin, phosphoric, lactic, and inosinic acid, and certain salts. Of course it contains no albumen or fibrin, unless in some altered state in which they are rendered soluble at a boiling temperature. In this nutritious biscuit, the absence of albumen and fibrin is supposed to be supplied by the vegetable fibrin (gluten) of the flour. The meat biscuit is said to be greatly superior in nutritive qualities to *pemmican*, used by the Hudson Bay Company and others, and which is made by mixing muscular flesh, cut in thin strips, thoroughly dried, and reduced to powder, with melted fat. To prepare a pint of palatable soup, an ounce of the powdered biscuit, first made into a thin paste with cold water, is added, with constant stirring, to sufficient boiling water, and the whole boiled for twenty minutes. Salt and pepper are then added to suit the taste. The meat biscuit forms an important resource in all cases in which food must be carried on long journeys for daily consumption.

MEDEOLA VIRGINICA. *Gyromia Virginica.* Nutall. *Indian Cucumber.* An indigenous perennial herb, growing in all parts of the United States. The root, which in shape and flavour bears a strong resemblance to a small cucumber, is said by Pursh to be eaten by the Indians. According to the late Professor Barton, it has been thought useful in dropsies, and probably possesses diuretic properties. It is figured and described by Dr. William P. C. Barton in his Medical Botany.

MELILOTUS OFFICINALIS. *Melilot.* An annual or biennial plant, indigenous in Europe, and growing also in this country. We have two varieties, one with yellow, the other with white flowers, which are considered by some as distinct species. The plant, when in flower, has a peculiar sweet odour, which, by drying, becomes stronger and more agreeable, somewhat like that of the tonka bean. Indeed, according to M. Guillemette, the odorous principle of the two substances is identical. (*Journ. de Pharm.*, xxi. 172.) The taste of melilot is slightly bitterish. It has little medical power, and, though formerly recommended in various diseases, is at present not employed internally. As a local application, it is used, in the form of decoction or cataplasm, in moderate inflammations, though probably with little other advantage than such as results from the combination of warmth and moisture.

MENISPERMUM CANADENSE. This is a climbing plant, growing in various parts of the United States, from the northern boundary to the Gulf of Mexico. It is described in the Flora of North America by Torrey and Gray (vol. i. p. 48). In an unpublished inaugural dissertation by Dr. Geo. F. Terrell (Feb. 1844), it is stated that the root of this plant is considerably employed in Virginia, both in domestic practice and by physicians, as a substitute for sarsaparilla, in scrofulous affections. It has a bitter taste, and is said to be a gently stimulating tonic.

MESEMBRYANTHEMUM CRYSTALLINUM. *Ice-plant.* A biennial plant, growing spontaneously in the South of Europe, and cultivated as a curiosity in colder countries, by the aid of artificial warmth. The stem and under surface of the leaves are covered with crystalline drops, which give the plant the appearance of being coated with ice. The herb is without smell, and has a saline somewhat nauseous taste. It is considered demulcent and diuretic, and has been highly lauded as a remedy in various complaints, especially in those affecting the mucous membrane of the lungs and urinary passages. It has also been used in dropsy. The expressed juice is the form in which the remedy has been generally employed.

MOMORDICA BALSAMINA. *Balsam Apple. Balsamina.* An annual climbing plant, a native of the East Indies, but cultivated in our gardens for the sake of the fruit. This is ovate, attenuated towards each extremity, angular, warty, not unlike a cucumber in appearance, of a lively red or orange-yellow colour, easily falling when touched, and spontaneously separating into several pieces. It was formerly highly esteemed as a vulnerary, and is still in use among the common people. A liniment formed by infusing the fruit, deprived of its seeds, in olive or almond oil, is applied to chapped hands, burns, old sores, piles, prolapsus ani, &c.; and the fruit itself is sometimes mashed and used in the form of poultice. According to M. Descourtlitz, it is poisonous when taken internally, having proved fatal to a dog in the quantity of two or three drachms. An extract prepared from it is said to be useful in dropsy, in the dose of from six to fifteen grains.

MONESIA. Under this name, a vegetable extract from South America was, a few years since, introduced to the notice of the medical profession in France by M. Bernard Derosne, and for a time attracted much attention. Its origin was for some time uncertain; but it appears to have been ascertained to be derived from the bark of *Chrysophyllum glycyphlœum*, a tree of middling size, growing in the forests near Rio Janeiro, and elsewhere in Brazil (Virey, *Journ. de Pharm.*, 3e *sér.*, vi. 63.) Specimens of the bark were obtained along with the extract.

The bark is in pieces, some of which are three or four lines thick, is very compact and heavy, of a deep-brown or chocolate colour, contrasting strongly with the grayish colour of the epidermis when this remains, and of smooth fracture. The extract was received from S. America in cakes weighing rather more than a pound, from three-quarters of an inch to an inch in thickness, of a dark-brown almost black colour, very brittle, of a fracture neither very dull nor very shining, and of a taste at first sweet, then astringent, and ultimately acrid; the acrimony being very persistent, and especially felt in the fauces. It is entirely soluble in water. The bark was analyzed by MM. Derosne, Henry, and Payen, and found to contain in 100 parts, 1·2 of stearin, chlorophylle, and wax, 1·4 of glycyrrhizin, 4·7 of an acrid principle analogous to saponin, called *monesin*, 7·5 of tannic acid, 9·2 of a red colouring substance, 1·3 of malic acid and malate of lime, 3·0 of various salts, including silica and oxides of iron and manganese, and 71·7 of pectic acid or pectin and lignin, including loss, besides traces of an aromatic principle, and of gum. *Monesin* was obtained by treating the bark or extract with alcohol, adding to the tincture an excess of hydrate of lime in fine powder, filtering, evaporating the clear liquor to dryness, treating the residue with water and animal charcoal, filtering, and again evaporating to dryness. Thus procured it was in transparent yellowish scales, which were easily pulverized, forming a white powder. It was readily dissolved by alcohol and water, to the latter of which it gave the property of frothing; but was insoluble in ether. It could not be made to crystallize. It had no power to saturate acids, was without odour, but had a slightly bitterish taste, followed by a very decided and permanent acrimony in the posterior mouth and fauces. (*Journ. de Pharm.*, Janvier, 1841.) Monesia owes its activity probably to this principle and to tannic acid.

The effects of this medicine upon the system appear to be those of a moderate stomachic excitant, a general alterative, and a feeble astringent. In over-doses, it is said to produce heat in the epigastrium with obstinate constipation and tenesmus. It has been used internally with asserted advantage in diarrhœa, hæmoptysis, menorrhagia, scrofula, scurvy, the chronic catarrh of old people, and dyspepsia. As a local remedy it has been found useful in leucorrhœa, ulcerations of the mouth and fauces, spongy and scorbutic gums, carious teeth, and obstinate scrofulous, and otherwise unhealthy ulcers upon the surface.

The extract may be given in pill or powder, in aqueous solution, in tincture, or in syrup. The dose of it is from two to ten grains, repeated every hour, two, or three hours, or less frequently. From ten grains to a drachm may be given daily. In scrofulous affections, it must be given in large quantities, and persevered in for several weeks, in order to obtain its curative effects. Monesia is applied to ulcers either by being sprinkled in powder upon the surface, or in the form of ointment made with one part of the extract and seven parts of simple ointment. Monesin, or the acrid principle, has been given internally in the dose of about half a grain, and has also been applied to ulcers.

Mr. Dupuy, of New York, states that specimens of an extract sold as monesia, which have come under his notice, bear so close a resemblance to extract of logwood as to suggest the inquiry, whether they might not really have been the product of the same plant. (*N. Y. Journ. of Pharm.*, i. 167.)

MOXA. The term *moxa* is employed to designate small masses of combustible matter intended, by being burnt in contact with the skin, to produce an eschar. They are of various forms, and made of different materials. The Chinese moxa is in small cones from eight to twelve lines in height, and is prepared from the leaves of one or more species of Artemisia. *A. Chinensis* and *A. Indica* were indicated by the Dublin College; but Lindley states that it is the *A. Moxa* of De Candolle which is employed. According to some authors, the part used is the down which covers the leaves and stems; but others, with greater probability, assert that it is a fine lanuginous substance, prepared from the leaves by beating them in a mortar. A coarser and a finer product are obtained, the former of which is used for tinder, the latter worked up into moxa. A similar moxa has been made in France, by a similar process, from the leaves of *A. vulgaris*.

Various substitutes have been proposed for the Chinese moxa, all composed of some light, porous, soft, inflammable substance, which burns slowly, and thus allows the heat to be regulated according to the effect desired. Linen rolled into a cylinder, cotton formed into the same shape and enclosed in a piece of linen, cords of cotton in small masses of various shapes, and even common spunk made from the agaric of the oak, have been employed by different persons with the desired effect. But all these bodies are subject to the inconvenience of requiring to be constantly blown upon, in order that their combustion may be sustained. To remedy this defect, cotton impregnated with nitre has been recommended; and the moxa usually employed is prepared from that substance. It is important that the impregnation should be uniform; as otherwise different parts of the cylinder, burning with different degrees of rapidity, would produce unequal effects upon the skin. The following process is recommended. One pound of cotton is introduced into a vessel containing two ounces of nitre dissolved in half a gallon of water, and a moderate heat applied, till all the liquid is evaporated. The cotton when perfectly dry is formed into thin, narrow sheets, which are rolled round a central cord of linen, so as to form a cylinder from half an inch to an inch in diameter, and several inches long. This is enclosed in a covering of silk or linen sewed firmly around it; and, when used, may be cut by a razor into transverse slices a few lines in length. By leaving a hole in the centre of the cylinder, the combustion will be rendered more vigorous, and a deeper eschar produced.

The pith of the *Helianthus annuus*, or common sun-flower, has been proposed by M. Percy for the preparation of moxa, for which it is well adapted by the nitre which it contains, and which enables it to burn without insufflation. The stem, when perfectly mature, is cut into transverse sections about half an inch in thickness, which must be carefully dried, and kept in a perfectly dry place. They have this advantage, that, in consequence of the retention of the cortical portion, they may be held with impunity, while burning, between the fingers of the operator. They are, however, frequently defective in consequence of an insufficiency of nitre in the pith, or of the unequal inflammability of different parts of it.

M. Robinet has perfected the preparation of moxa, by combining the advantages of the two kinds last described. He rolls cotton round a small central cylinder of pith, and envelopes the whole in a piece of muslin, which is more or less firmly applied, according to the degree of compactness required. The cylinders thus made, burn without assistance, uniformly, and with a rapidity proportionate to their firmness.

Dr. Jacobson, of Copenhagen, has proposed, as a substitute for the ordinary forms of moxa, small cylinders formed out of strips of paper imbued with a solution of chromate of potassa; and cotton, impregnated with the solution of chlorate of potassa instead of nitre, is said to answer an excellent purpose. (*Journ. de Pharm.*, xix. 608.) Small cylinders made out of strips of coarse muslin imbued with the same solution are also employed. M. Guepratt proposes paper or cotton dipped into the solution of subacetate of lead, and afterwards dried. (*Med. Exam.*, N. S., iii. 455, from *London Lancet.*)

Lime in the act of slaking has been employed by Dr. Osborne for the purposes of

moxa. A portion of powdered quicklime, half an inch in thickness, and of suitable lateral dimensions, is applied to the skin, and confined by some convenient arrangement. A few drops of water are then added, and a degree of heat is soon evolved sufficient for a caustic effect, if the lime be allowed to remain as long as the heat continues. This may be increased or diminished by increasing or diminishing the quantity of lime employed. The eschar formed is somewhat more than double the extent of the base of the moxa. (*Dublin Journ.*, Jan. 1842.)

Medical Use. Cauterization by fire, in the treatment of disease, has been commonly practised among savage and half civilized nations from the earliest periods of history, and has not been unknown as a remedy in the most polished communities. The ancient Egyptians and Greeks were acquainted with the use of moxa; and in China, Japan, and other countries of Asia, it appears to have been employed from time immemorial. From these countries the early Portuguese navigators introduced it into Europe; and the term *moxa* is said to have been derived from their language, though supposed by some to be of Chinese origin. The true Chinese name is said to be *kiew*. (*Percy and Laurent.*) Some years since, the remedy became very popular in France, and attracted some attention in this country. It acts on the principle of revulsion; relieving deep-seated inflammation, and local irritation whether vascular or nervous, by inviting the current of excitement to the skin. In some cases it may also operate advantageously by the propagation of a stimulant impression to neighbouring parts.

The celebrated Larrey was among those who contributed most to bring this remedy into repute. The diseases in which it was recommended by this author were amaurosis, loss of taste, deafness, paralytic affections of the muscular system, asthma, chronic catarrh and pleurisy, phthisis, chronic engorgement of the liver and spleen, rachitis, diseased spine, coxalgia, and other forms of scrofulous and rheumatic inflammation of the joints. It has also been used advantageously in neuralgia, and is applicable to chronic complaints generally in which powerful external revulsion is indicated.

The parts of the body upon which, according to Larrey, it should not be applied, are the cranium where protected only by the skin and pericranium; the eyelids, nose, and ears; the skin over the larynx, trachea, and mammary glands, over superficial tendons, projecting points of bones, and articular prominences in which the capsular ligament might be involved; the anterior surface of the abdomen; and the genitals.

As a general rule it should be applied as near as possible to the seat of the disease; and, in neuralgic or paralytic cases, at the origin or over the course of the nerves proceeding to the part affected. Some advise that the cylinder be attached to the skin by some adhesive liquid; but a more general practice is to retain it in the proper position by a pair of forceps or other instrument. Larrey recommends that the skin around it be covered with a piece of moistened lint, having a hole in the centre to admit the base of the cylinder. The moxa should be set on fire at the summit, and the combustion sustained if necessary by the breath, the blow-pipe, or the bellows. The size of the cylinder should vary, according to the effect desired, from half an inch to an inch or more in diameter, and from a few lines to an inch in height. Any degree of effect may be obtained, from a slight inflammation to the death of the skin, by regulating the time during which the moxa is allowed to burn. When a slough is required, it should be suffered to burn until consumed. The first sensation experienced is not disagreeable; but the operation becomes gradually more painful, and towards the close is for a short time very severe.

MURIATIC ETHER. *Æther Muriaticus. Muriate of Etherine. Chloride of Ethyle.* This ether was discovered by Rouelle, but first obtained in sufficient quantities to permit the examination of its properties by Basse. It may be procured by several processes, but the following is the best.—Distil a mixture of equal measures of concentrated muriatic acid and alcohol, and receive the product, by means of a curved glass tube, in a tubulated bottle, half filled with water at a temperature between 70° and 80°, and connected by means of a second tube with another bottle, loosely corked, and surrounded by a mixture of common salt with snow or pounded ice. The ether which comes over into the first bottle, is mixed with alcohol and acid, which are retained by the water, while the pure ether passes forward, and is condensed in the refrigerated bottle. This ether must be kept in strong bottles, well secured with ground stoppers covered with leather. Before being opened, the bottle should be cooled down to the freezing point.

Muriatic ether is colourless, has a strong, slightly saccharine, alliaceous taste, and a penetrating, ethereal, alliaceous smell. Its sp. gr. at the temperature of 41° is 0·774. It is extremely volatile, entering into ebullition at 54°; so that in summer it may be collected in the gaseous state, in bell-glasses over water. Its density in the state of vapour is 2·22. When kindled as issuing from a fine orifice, it burns with an emerald-green flame without smoke, diffusing a strong odour of muriatic acid; but when set on fire in quantities, it burns with a greenish-yellow smoky flame. Water dissolves one-fiftieth of its weight of

this ether, and acquires a sweetish, ethereal taste, and alcohol unites with it in all proportions. These solutions are not precipitated by nitrate of silver, showing that the chlorine present is in a peculiar state of combination. Like sulphuric and nitric ether, it dissolves sulphur and phosphorus, the fat and volatile oils, and many other substances. It consists of one eq. of muriatic acid 36·42, and one of etherine 28=64·42; or, in volumes, of two volumes of the acid, and one volume of the vapour of etherine, condensed into two volumes. Viewed as the chloride of ethyle, its formula is C_4H_5Cl.

Muriatic ether, like the other substances of this class, is a diffusible stimulant; but, owing to its extreme volatility, cannot be kept in the shops. It may, however, be preserved in a cool cellar, the temperature of which does not rise above 45° or 50°, being well secured in bottles, which should be placed reversed. When used as a medicine, it is generally mixed with an equal bulk of alcohol, forming what is called *alcoholic muriatic ether*. The dose is from five to thirty drops, given in sweetened water, or other convenient vehicle.

MUSHROOMS. *Fungi.* This extensive family of cryptogamous plants is interesting to the physician, from the consideration, that, while some of them are very largely consumed as food, others are deleterious in their nature, and capable, when eaten, of producing poisonous effects. Their substance is made up of a cellular tissue, which is usually of that soft consistence denominated fungous, but is sometimes corky, ligneous, or even gelatinous. Many of them have an agreeable odour and taste, while others are unpleasant or offensive both to the nostrils and palate. Their juice generally exhibits an acid reaction. According to Braconnot, most of them contain, among other substances, a peculiar principle denominated *fungin*, a peculiar acid called *fungic acid* usually combined with potassa, and a peculiar saccharine matter less sweet than the other varieties of sugar, less soluble in alcohol and water than that of the cane, and distinguished by some writers as the *sugar of mushrooms*. M. Bolby found *mannite* in two different species, with *oxalic acid* in one, an acid which he supposed to be the *fumaric* in a second, and the *lichenstearic acid* in a third. (*Journ. de Pharm.*, 3e *sér.*, xxiv. 236.) *Fungin* constitutes the basis of these vegetables, and is the principle upon which their nutritive properties chiefly depend. It is the fleshy substance which remains when they are treated with boiling water holding a little alkali in solution. It is whitish, soft, and insipid; inflammable; insoluble in water, alcohol, ether, weak sulphuric acid, and weak solutions of potassa and soda; soluble in heated muriatic acid; decomposed by nitric acid, and by concentrated alkaline solutions; and converted by destructive distillation into substances resembling those which result from the distillation of animal matters.

It is highly important for those who employ mushrooms as food, to be able to distinguish those which are wholesome from the poisonous. The following general rules were given by M. Richard in the *Dictionnaire des Drogues*. Those should be rejected which have a narcotic or fetid odour, or an acrid, bitter, or very acid taste; which occasion a sense of constriction in the throat when swallowed; which are very soft, liquefying, changing colour, and assuming a bluish tint upon being bruised; which exude a milky, acrid, and styptic juice; which grow in very moist places, and upon putrefying substances; in fine, all such as have a coriaceous, ligneous, or corky consistence. The last, however, are injurious in consequence rather of their indigestible than of their poisonous nature. Even mushrooms which are usually edible, may prove poisonous, if collected too late, or in places which are too moist. It is said, moreover, that the poisonous species sometimes become innocent when they grow under favourable circumstances. Immense quantities of mushrooms are eaten in France, Germany, Italy, and other parts of continental Europe; and they are said to constitute the chief food of the people in certain provinces.

Some experiments of M. Gerard would tend to show that poisonous mushrooms may be rendered innocent, by treating them with water slightly acidulated with vinegar, before cooking them. About a pound avoirdupois of poisonous mushrooms, cut into pieces, are to be macerated for two hours in a quart of water, acidulated with two or three spoonfuls of strong vinegar, and afterwards to be washed with a large quantity of water. Next day they are to be put into cold water, boiled for half an hour, then taken out, washed, and dried. They are now fit for food. (See *Am. Journ. of Pharm.*, xxv. 274.) But subsequent experiments by MM. Demartis and Corne, of Bordeaux, have proved that this method is not always to be relied on; as certain mushrooms, after having been treated in the manner suggested, have nevertheless produced fatal effects on animals to which they were given; and as the same mushrooms may be poisonous at one season, or in one situation, and innocent in another, the inference is that those experimented on by M. Gerard, though ordinarily poisonous, may not have been so in that particular instance. (*Journ. de Pharm.*, 3e *sér.*, xxi. 468.)

The symptoms produced by the poisonous mushrooms are anxiety, nausea, faintness, vomiting, and, if they are not rejected from the stomach, somnolence, stupor, small and

intermittent pulse, tension of the abdomen, cold extremities, livid skin, and death in thirty-six or forty-eight hours. Sometimes violent pains in the stomach and bowels are experienced; and occasionally severe vomiting and purging occur, and save the patient. The remedies are emetics, if the physician is called in time, accompanied with the free use of warm drinks, and followed by cathartics. After the evacuation of the alimentary canal, demulcent and nutritive beverages should be given, and the strength of the patient sustained by mild tonics or stimulants. Ether is particularly recommended.

Some of the poisonous species have been used as medicines; but in this country they are never employed; and too little seems to be precisely known of their modes of action, and their qualities, even in the same species, vary too much, according to the circumstances of their growth and situation, to justify their introduction into the materia medica, without further investigation. A species of *Lycoperdon* or puff-ball, *L. proteus*, has been proved by Mr. B. W. Richardson, of London, to have remarkable narcotic and anæsthetic properties. Having noticed that the smoke of this fungus was used in the country for stupefying bees, he made experiments with the fumes upon various animals, which, when caused to inhale them, became insensible, and could be operated on without evincing any signs of pain. When carried far, they caused death. He had himself inhaled the fumes clarified by passing them through water, and experienced symptoms of intoxication and drowsiness. They were procured by burning the fungus. (*Lond. Med. Times and Gaz.*, June, 1853, p. 610.)

MUSK, ARTIFICIAL. *Moschus Factitius.* This is prepared, according to M. Elsner, by adding, by small portions at a time, one part of rectified oil of amber to three parts of fuming nitric acid. The resulting resin is washed with water to separate acid, and brought to the consistence of a firm extract in a water bath. Thus prepared it is a dark brownish-red substance, having a burning, bitter, aromatic taste, and a musky odour. It is very soluble in alcohol, ether, and the volatile oils; its alcoholic solution reddening litmus. Triturated with caustic potassa, it gives off ammonia. When set on fire, it burns with a very smoky flame, and leaves a shining, porous charcoal. Its formula, deduced from its combination with protoxide of lead, is $N_2C_{15}H_8O_7$. Comparing its composition with that of the oil of amber, the action of the nitric acid evidently consists in eliminating a portion of carbon and hydrogen, adding to the oxygen, and furnishing nitrogen. M. Elsner found oil of amber to consist of several oily principles, having different boiling points, one of which, resembling eupione, he calls *amber eupione*. As this substance yields artificial musk by the action of fuming nitric acid, he believes the property possessed by oil of amber of yielding the same substance is due to its presence. (*Journ. de Pharm.*, 3e *sér.*, ii 144.) During the reaction of nitric acid with oil of amber, Dr. John T. Plummer, of Indiana, has observed that oxalic acid is generated. (*Am. Journ. of Pharm.*, Jan. 1852, p. 36.)

Dr. S. W. Williams gives the following formula for the preparation of artificial musk. Add gradually, drop by drop, *three drachms and a half* of concentrated nitric acid to *a drachm* of rectified oil of amber, contained in a glass tumbler, or very large wineglass. The mixture grows hot, and emits offensive fumes, which the operator must avoid. When the ordinary nitric acid is employed, which is not of full strength, the reaction must be assisted by heat; in which case Dr. Williams recommends that the vessel containing the mixed ingredients be placed in a plate before the fire, they being, meanwhile, continually stirred with a glass rod. After the mixture has remained at rest for twenty-four hours, it acquires a resinous appearance, and divides into two portions, an acid liquid below, and a yellow resin above resembling musk in smell. This being thoroughly washed, first with cold and then with hot water, until all traces of acid are removed, is the artificial musk. (*Am. Journ. of Pharm.*, viii. 14, from the *Boston Med. and Surg. Journ.*)

Artificial musk is an antispasmodic and nervine, and possesses the general therapeutic properties of the natural substance, though in a weaker degree. It is praised by Dr. Williams in the treatment of hooping-cough, typhoid states of fever, and nervous diseases generally. When combined with water of ammonia, compound spirit of lavender, or laudanum, he found no remedy so efficient in the sinking faintness occurring in the last stage of pulmonary consumption. The average dose for an adult is ten grains; for a child of two years old, from half a grain to a grain, repeated, in each case, every two or three hours. It may be prepared as the musk mixture, or with almonds in the form of emulsion. According to Berzelius, the tincture is formed by dissolving *a drachm* of artificial musk in *an ounce* of alcohol, equivalent to *ten fluidrachms* of the sp. gr. 0·835. Of this the dose for an adult is a teaspoonful. Though artificial musk is not equal in power to the natural substance when genuine, yet it is in all probability superior to the adulterated article, so frequently sold under the name of musk.

MYROBALANS. *Myrobalani.* These are the fruits of various East India trees, particularly of different species of Terminalia. They are noticed here partly on account of

their ancient reputation, partly because they are still occasionally to be found in the shops, though seldom, if ever used in medicine. Five varieties are distinguished by authors. 1. *Myrobalani bellericæ.* These are obtained from *Terminalia Bellirica.* They are roundish or ovate, from the size of a hazelnut to that of a walnut, of a grayish-brown colour, smooth, marked with five longitudinal ribs, and sometimes furnished with a short, thick footstalk. They consist of an exterior, thin, firm, resinous, brown, fleshy portion, and an interior kernel, which is light-brown, inodorous, and of a bitterish very astringent taste. 2. *Myrobalani chebulæ.* This variety is produced by *Terminalia Chebula.* The fruit is oblong, pointed at each extremity, from fifteen to eighteen lines in length, of a dark-brown colour, smooth and shining, with five longitudinal wrinkles, but without footstalks. In their internal arrangement and their taste, they resemble the preceding. 3. *Myrobalani citrinæ* vel *flavæ.* These are from a variety of the same tree which affords the last-mentioned myrobalans, from which they differ only in being somewhat smaller, of a light-brown or yellowish colour, and of a taste rather more bitter. They were formerly sometimes sold in the shops in Philadelphia, under the name of *white galls*, to which, however, they bear no other resemblance than in taste. 4. *Myrobalani Indicæ* vel *nigræ.* These are thought to be the unripe fruit of *Terminalia Chebula*, or *T. Bellirica.* They are ovate-oblong, from four to eight lines long, and from two to three lines thick, of a blackish colour, wrinkled longitudinally, and presenting, when broken, a thick brown mass, without kernel, but with a small cavity in the centre. They are sourish and very astringent. 5. *Myrobalani emblicæ.* This variety is wholly different from the preceding, and derived from a plant having no affinity to the Terminaliæ, namely, the *Phyllanthus Emblica* of Linnæus. It is often in segments, as kept in the shops. When the fruit is entire, it is blackish, spherical, depressed, of the size of a cherry, presenting six obtuse ribs with as many deep furrows, and separating into six valves, and has a strongly astringent and acidulous taste.

These fruits were in high repute with the Arabians, and were long employed by European practitioners, as primarily laxative and secondarily astringent, in various complaints, particularly diarrhœa and dysentery. Their dose was from two drachms to an ounce. They are not now employed as medicines. We have been told that they have been used as a substitute for galls in the preparation of ink-powder.

NAPHTHALINE. This may be obtained by subjecting coal-tar to distillation, when it passes over after the coal-naphtha. It is a white, shining, concrete, crystalline substance, fusible at 176° and boiling at 423°. It is soluble in alcohol, ether, naphtha, and the oils, but insoluble in water. It has been proposed by Dupasquier as an expectorant, and has been found, on trial, to act decidedly as such. In the impending suffocation, sometimes occurring in the chronic pulmonary catarrh of old persons, and in humoral asthma, it facilitated expectoration in a remarkable degree. Being a stimulating remedy, it is not proper in acute bronchitis, or where pulmonary inflammation exists. The dose is from eight to thirty grains, given in emulsion or syrup, and repeated at intervals of a quarter of an hour, until an abundant expectoration takes place. (*Journ. de Pharm.*, 3*e sér.*, ii. 513.) M. Rossignon considers naphthaline to act like camphor, and to be capable of replacing it on many occasions as a remedy. It produces excellent effects in verminose affections. It has been found useful by M. Emery, in the form of ointment made by mixing a scruple of naphthaline with five drachms of lard, in dry tetter, psoriasis, and lepra vulgaris. (*Annuaire de Thérap.*, 1843, pp. 64 and 66.)

NAPLES YELLOW. A yellow pigment prepared by calcining a mixture of lead, sulphuret of antimony, dried alum, and muriate of ammonia, or a mixture of carbonate of lead, diaphoretic antimony, dried alum, and muriate of ammonia. (*Gray.*)

NARCISSUS PSEUDO-NARCISSUS. *Daffodil.* This well-known bulbous plant is a native of Europe, but is very common in the gardens of this country, where it attracts attention by the early appearance of its conspicuous yellow flowers. Both the bulb and flowers have been used in medicine. The latter have a feeble peculiar odour, and both have a bitter mucilaginous taste. They are emetic, though uncertain in their operation. It is probable that the flowers of the wild plant are more powerful than those of the cultivated. They may be given dried and powdered, or in the form of extract. The dose of the powder, to produce an emetic effect, varies, according to the statements of different physicians, from a scruple to two drachms; while the extract is said to vomit in the dose of two or three grains. It is conjectured that the emetic property is developed by the agency of water. The bulb is most powerful in the recent state, and, within our own knowledge, is occasionally used as an emetic in domestic practice in this country. When dried and powdered, it has been given in the dose of thirty-six grains without vomiting. The flowers are said also to possess antispasmodic powers, and have been used in France, with supposed advantage, in hooping-cough, epilepsy, and other convulsive affections. It is probable, however, that they operated in these cases by their nauseating or emetic

property. They have, moreover, been advantageously employed in diarrhœa, dysentery, and intermittent fever. Other species of Narcissus are said to possess the same properties, though they have not been so much used.

NARD. *Spikenard.* Several aromatic roots were known to the ancients under the name of *nardus*, distinguished, according to their origin or place of growth, by the names of *nardus Indica*, *nardus Celtica*, *nardus montana*, &c. They are supposed to have been derived from different species of *Valeriana*. Thus the nardus Indica is referred to *V. Jatamensi* of Bengal, the nardus Celtica to *V. Celtica*, inhabiting the Alps, Apennines, &c., and the nardus montana to *V. tuberosa*, which grows in the mountains of the South of Europe. The Indian nard, or spikenard, sometimes also called Syrian nard, is still occasionally to be found in the shops. It is a small delicate root, from one to three inches long, beset with a tuft of soft, light-brown, slender fibres, of an agreeable odour, and a bitter, aromatic taste. It was formerly very highly esteemed as a medicine, but is now almost out of use. Its properties are analogous to those of the officinal valerian.

NASTURTIUM OFFICINALE. R. Brown. *Sisymbrium Nasturtium.* Linn. *Water-cress.* A small, perennial, herbaceous, succulent plant, growing in springs, rivulets, and ponds, in North America, Europe, and some parts of Asia. The fresh herb has a quick penetrating odour, especially when rubbed, and a bitterish, pungent taste, but loses both when dried. In sensible and medical properties it bears some resemblance to scurvy grass, though milder, and on this account is preferred for the table. It is thought to be useful in scorbutic affections, and visceral obstructions. The expressed juice is sometimes given in the dose of one or two ounces; but the herb is more frequently used in the form of a salad. Other species of Nasturtium, as *N. palustre*, or *marsh water-cress*, and *N. amphibium* or *water-radish*, grow in similar situations with the *N. officinale*, and possess similar virtues.

NIGELLA SATIVA. *Nutmeg-flower. Small fennel-flower.* A small annual plant, growing wild in Syria and the South of Europe, and cultivated in various parts of the world. The seeds, which are sometimes kept in the shops under the name of *semen nigellæ*, are ovate, somewhat compressed, about a line long and half as broad, usually three-cornered, with two sides flat and one convex, black or brown externally, white and oleaginous within, of a strong, agreeable, aromatic odour, like that of nutmegs, and a spicy pungent taste. Their chief constituents are a volatile and fixed oil, and a peculiar bitter principle denominated *nigellin*, which exists in the seeds in very minute proportion. (*Journ. de Pharm.*, *3e sér.*, ii. 128.)

NITRATE OF COPPER. *Cupri Nitras.* This well known salt has been employed with advantage as a caustic, in a severe case of ulceration of the throat and tongue, and in several similar cases, by Dr. William Moore, of Ballymoney, Ireland. The application is attended with no danger, provided the ulcer or part is dried before applying the caustic, and afterwards smeared with oil. (See *Braithwaite's Retrospect*, xxv. 201.)

NITRATE OF SODA. *Cubic Nitre.* This salt may be formed by treating carbonate of soda with nitric acid. It is found naturally, in inexhaustible quantities, in the desert of Atacama and elsewhere, in Peru, where it forms beds of vast extent. Attempts were made between 1820 and 1830 to export it to England and the United States; but the cargoes were unsalable. Soon afterwards, however, its value came to be known; so that at present large quantities are exported from Peru, being consumed in the manufacture of sulphuric and nitric acids, and as a fertilizer. Considerable quantities have been brought to the United States.

Nitrate of soda, when pure, is a white salt, crystallizing in rhomboidal prisms, and having a sharp, cooling, and bitter taste. It attracts moisture slightly from the air, and dissolves in about twice its weight of water at 60°. It has been praised as a remedy in dysentery by two German physicians, Drs. Velsen and Meyer, given in the quantity of from half an ounce to an ounce in the course of the day, dissolved in gum water or other mucilaginous liquid. The crude salt, as it comes from Peru, is in saline lumps, rather soft and friable, and damp on the surface. It is distinguished into varieties, according to its colour and state of aggregation; as *white compact, yellow, gray compact, gray crystalline*, and *white crystalline;* and varies very much in purity, from containing eighty-five to only twenty per cent. of the pure salt. Some of the varieties contain iodine. (See *page* 41.) The impurities consist of common salt, sulphate and carbonate of soda, and chloride of calcium. Occasionally, borate of lime is found, associated with borate of soda, under the beds of the nitrate. (See *page* 687.)

As nitrate of soda has been imposed upon our merchants for nitre, it may be useful to mention that the former salt may be distinguished by its giving rise to an orange-yellow flame when thrown on burning coals, and by the rhomboidal shape of its crystals; those of nitre being long six-sided prisms. (See *page* 590.)

NITROPRUSSIDE OF SODIUM. This is the most interesting of a series of salts, discovered by Dr. Playfair, called *nitroprussides*, which are produced, for the most part, by saturating the acid (*nitroprussic acid*), generated by the action of nitric acid on ferrocyanuret of potassium, with different bases. The sodium salt is best obtained by the process of A. Overbeck, as follows.—Dissolve *four parts* of powdered ferrocyanuret of potassium contained in a flask, in *five and a half parts* of commercial nitric acid, diluted with an equal weight of water. After the action is completed, which generally occupies about ten minutes, and is accompanied by a copious evolution of gases, heat the resulting coffee-brown liquid by a water bath, until a drop of it gives a dingy green, instead of a blue precipitate with a solution of sulphate of protoxide of iron. Then allow the liquid to cool; whereupon the larger part of the nitrate of potassa generated will be deposited in crystals. Pour off the green mother-liquor from these, and separate the remaining nitrate of potassa by repeated concentrations. Next neutralize the liquid, while heated on a water bath, with carbonate of soda, taking care to add the carbonate so long only as a pure blue precipitate is produced. Lastly, filter the solution, and set it aside that crystals may form, which must be washed with water, and dried between blotting paper. (*Chem. Gaz.*, July 15, 1853, p. 271.) This salt is in the form of large ruby-coloured prismatic crystals, very much resembling those of ferridcyanuret of potassium (red prussiate of potassa). It is soluble in two and a half parts of cold water, and in a less quantity of hot water. Its solution, exposed to sunshine, is decomposed, with evolution of nitric oxide gas, and deposition of Prussian blue, at the same time acquiring a green colour. Nitroprusside of sodium, as well as the other soluble nitroprussides, is a most delicate test for the alkaline sulphurets, with which it strikes a beautiful violet colour. (See *page* 716.) Its composition is not certainly known; but the following formula, given by Gerhardt, is probably the correct one. ($Na_2.Fe_2Cy_5NO_2+4HO.$) Nitroprussic acid is the nitroprusside of hydrogen, with the formula $H_2,Fe_2Cy_5NO_2$.

NITROSULPHATE OF AMMONIA. This compound, discovered by Pelouze in 1835, may be formed by passing nitric oxide through a solution of sulphate of ammonia in five or six times its volume of water of ammonia. A large number of crystals are formed, which must be quickly washed with liquid ammonia previously refrigerated, and dried without heat. Nitrosulphate of ammonia has been used at the Hotel Dieu in Paris, in doses of twelve grains, with apparent advantage, in typhoid fevers. Its composition corresponds with one eq. of nitric oxide, one of sulphurous acid, and one of ammonia; but as the salt is not precipitated by barytic water, Pelouze conceives that the nitric oxide and sulphurous acid, together, form a peculiar acid which he calls *nitrosulphuric acid*, consisting of one eq. of nitrogen, one of sulphur, and four of oxygen.

NITROUS OXIDE. This well known gas, generally called the laughing gas, from its power to cause a transient intoxication when breathed, is capable of producing anæsthetic effects; but even if these were as safely induced as by ether, the comparative expense of the gas would prevent its employment. The late Mr. Horace Wells, dentist, of Connecticut, tried to introduce it as an anæsthetic; but his first experiments were unsuccessful, and further attempts were superseded by the discovery of etherization.

Water, impregnated by pressure with about five times its volume of this gas, forms the *nitrous oxide water*, known in England under the name of Searle's patent oxygenous aërated water, which has been used to some extent as an internal remedy. Sir H. Davy tried the aqueous solution, made without pressure, and thought it acted as a diuretic, and promoted digestion; and Serullas used it in Asiatic cholera with apparent advantage. The patent water is asserted to be suited to the treatment of torpor, debility, depression of spirits, asthma, and dyspepsia; but to be contra-indicated in inflammatory and plethoric states of the system. Dr. George J. Ziegler, of Philadelphia, has made a number of therapeutic trials with nitrous oxide water, charged with five times its volume of the gas, and finds it to possess tonic, resolvent, exhilarant, and diuretic properties. He has observed, however, that its free and prolonged use is apt to produce emaciation. Dr. Ziegler has also made some interesting experiments, tending to show the antidotal and revivifying properties of nitrous oxide. In these experiments, dogs were asphyxiated or poisoned with carburetted hydrogen, chloroform, carbonic acid, hydrocyanic acid, and other agents, and, when in a state of suspended animation more or less complete, were generally revived by the nitrous oxide water, injected into the bowels in the amount of from two to three pints. When administered by the stomach, the dose of the water is from half a pint to a pint and a half, taken in the course of the day. Dr. Ziegler concludes from his observations and experiments that nitrous oxide is a powerful arterial, nervous, and cerebral stimulant, possessing, at the same time, valuable antidotal powers. (*Boston Med. and Surg. Journ.*, xlvi. 453 and xlvii. 383.)

NYMPHÆA ODORATA. *Sweet-scented Water-lily.* An indigenous herbaceous perennial, growing in most parts of the United States, in fresh water ponds and the borders

of streams, and distinguished by the beauty and delicious odour of its large, white, many-petaled flowers. Its root is large and fleshy in the recent state, but becomes light, spongy, and friable by drying. It is very astringent and bitter, and, according to Dr. Bigelow, contains much tannin and gallic acid. It is sometimes employed, in the form of poultice, as a discutient application. The root of the *Nymphæa alba*, or European *white water-lily*, was esteemed aphrodisiac by the ancients, but has long lost this reputation. Like that of the American plant, it is bitter and styptic, and may have been useful by its astringency in some cases of leucorrhœa, gonorrhœa, dysentery, &c., in which it was formerly employed for its reputed sedative virtues.

OCHRES. These are native mixtures of argillaceous or calcareous earth and oxide of iron, employed in painting. They are prepared for use by agitating them with water, decanting the turbid liquor after the coarser particles have subsided, then allowing it to rest in order that the finer parts may be deposited, and, lastly, drying the sediment which forms. The colour of the ochres varies with the state of oxidation of the iron, and with the proportion which it bears to the other ingredients, and is sometimes artificially modified by the agency of heat. Several varieties are kept in our shops under different names, according to their colour or place of origin. Such are the *brown ochre*, the *yellow ochre*, the *red ochre*, the *Roman ochre* of a brownish-yellow changing by heat to a purple-red, the *Oxford ochre* of a brownish-yellow colour less deep than the Roman, and the *French ochre* which is yellow. The *Indian red* from the Persian Gulf, the *Spanish brown*, may also be ranked in this class of pigments. Sometimes ochres come in a powdery state, and sometimes in hard masses; in the latter state they are called *stone ochres*.

OCIMUM BASILICUM. *Basil.* An annual plant, a native of India and Persia, and cultivated in Europe and in this country in gardens. The whole plant has a strong, peculiar, agreeable, aromatic odour, which is improved by drying. The taste is aromatic, and somewhat cooling and saline. Basil has the ordinary properties of the aromatic plants, and is in some places considerably used as a condiment. The seeds are said by Ainslie to be used in India, in the form of infusion, as a remedy in gonorrhœa and nephritic affections.

ŒNANTHE CROCATA. *Hemlock Water-dropwort.* A perennial umbelliferous aquatic European plant, exceedingly poisonous both to men and inferior animals. The root, which has a sweetish, not unpleasant taste, is sometimes eaten by mistake for other roots, with the most dangerous effects; and numerous instances of fatal results are on record. The symptoms produced are such as attend irritation or inflammation of the stomach, united with great cerebral disturbance, indicated by giddiness, convulsions, and coma. Externally applied, the root produces redness and irritation of the skin, with an eruptive affection. It is said to be sometimes used empirically as a local remedy in piles; and a case is recorded in which an obstinate leprosy was cured by the continued use of the juice of the plant. Other species of *Œnanthe* are poisonous, and the whole genus should be regarded among the suspected plants. We have two or three indigenous species. The proper remedies, in cases of poisoning from these plants, are emetics, followed, after the stomach has been thoroughly evacuated, by demulcent drinks. A peculiar resinoid principle, denominated *œnanthin*, has been found by M. Gerding in Œnanthe fistulosa, of which half a grain, given to an adult, produced long-continued irritation of the fauces, with hoarseness, and a grain occasioned vomiting. (See *Am. Journ. of Pharm.*, xxi. 68.)

ŒNANTHE PHELLANDRIUM. Sprengel. *Phellandrium aquaticum.* Linn. *Fine-leaved Water-hemlock.* A biennial or perennial, umbelliferous, European water plant, the fresh leaves of which are said to be injurious to cattle, producing a kind of paralysis when eaten. By drying, they lose their deleterious properties. The *seeds* have been used in Europe to a considerable extent in the treatment of disease. They are from a line to a line and a half in length, ovate-oblong, narrow above, somewhat compressed, marked with ten delicate ribs, and crowned with the remains of the calyx, and with the erect or reverted styles. Their colour is yellowish-brown; their odour peculiar, strong, and disagreeable; their taste acrid and aromatic. Among their constituents is a volatile oil, upon which their aromatic flavour depends. By different writers they are described as aperient, diuretic, emmenagogue, expectorant, and sedative. They probably unite mild narcotic properties with the stimulant powers which are common to most of the aromatics, and may be directed, according to circumstances, to different secretory organs. In over-doses they produce vertigo, intoxication, and other narcotic effects. They appear to have been used most successfully in chronic pectoral affections, such as bronchitis, pulmonary consumption, and asthma. They have been given also in dyspepsia, intermittent fever, obstinate ulcers, &c. The dose of the seeds, to commence with, is five or six grains, so repeated as to amount to a drachm in twenty-four hours. They should be given in powder. A tincture and alcoholic extract of the seeds have been prepared, of which the former, containing the

virtues of half a drachm of the seeds in a fluidounce, is given in the dose of from f℥ss to f℥j, and the latter in that of three to five grains. (*Pharm. Journ. and Trans.*, xii. 591.)

ŒNOTHERA BIENNIS. *Tree Primrose.* A biennial indigenous plant, growing in fields and along fences, from Canada to the Carolinas. It is from two to five feet high, with a rough stem, alternate, ovate-lanceolate leaves, and fine yellow flowers, which make their appearance in July and August. Schoepf states that it is esteemed useful as a vulnerary. The late Dr. R. E. Griffith found a strong decoction of the small branches, with the leaves and cortical part of the stem and larger branches, very beneficial in eruptive complaints, especially tetter. He applied the decoction several times a day to the affected part. He believed the virtues of the plant to reside in the cortical part, which has a mucilaginous taste, and leaves a slight sensation of acrimony in the fauces. (*Journ. of the Phil. Col. of Pharm.*, iv. 292.)

OIL OF ANDA. A fixed oil procured by expression from the seeds of *Anda Brasiliensis* (Radde), *Anda Gomesei* (Ad. Jussieu), a tree of Brazil, belonging to the family of Euphorbiaceæ. The bark yields on being wounded a milky juice, which is said to be poisonous, and to be used for stupefying fish. The fruit, which is about as large as an apple, ash-coloured, with two larger and two smaller angles, encloses a two-celled nut, containing two seeds, about the size of a chestnut. Like the seeds of other Euphorbiaceous plants, these are actively purgative; one seed, according to Martius, being the dose for a man. By expression these seeds yield a pale-yellow transparent oil, with little smell or taste, which is said to be used in Brazil for burning and painting. Dr. Norris, who tried the oil at the Pennsylvania Hospital, found it to operate on the bowels moderately in the dose of fifty drops, and copiously, when more largely given. (*Cyclopædia of Pract. Med. and Surg.*, i. 470.) Dr. Alexander Ure, who has experimented with it in several cases, states that, in the average dose of twenty drops, it usually operates mildly, without producing heat or pain in the throat, and seldom causing nausea or vomiting.

OIL OF BEN. This is a fixed oil extracted from the seeds of the *Moringa pterygosperma* and *M. aptera* of *Gærtner*, confounded by Linnæus under the name of *Guilandina Moringa*. *Hyperanthera Moringa* (Vahl) is a synonyme of the former species. These are trees belonging to the family of *Leguminosæ*, inhabiting different parts of India, Arabia, Syria, &c., and introduced into the W. Indies. The leaves and other parts have an acrid property, which has probably given the name of *horseradish tree* to M. pterygosperma. The oil of the seeds has long been known, though used rather in the arts than in medicine. Most of it is prepared in Europe from seeds brought from Egypt (*Merat and De Lens*); but it is said also to be extracted in the W. Indies. It is inodorous, clear, and nearly colourless, and keeps long without becoming rancid. It is employed for similar purposes with olive oil. Merat and De Lens say that it is purgative; but most of the fixed oils are so in sufficient doses. According to Völker the oil contains margarin, olein, and a peculiar fatty matter yielding an acid by saponification, which he proposes to call *benic acid.* (*Journ. de Pharm. et de Chim.*, xvi. 77.)

OIL OF CADE. *Oleum Cadinum. Huile de Cade.* French. This is a kind of tar obtained by distillation *per descensum* from the interior reddish wood of *Juniperus communis*, or more strictly of *J. Oxycedrus*, which grows in the South of France where the substance is prepared. It is a thick liquid, black, and of a smell analogous to that of common tar. It has long been employed in the treatment of the cutaneous diseases of horses, sheep, &c.; and was also applied by the peasantry to their own skin affections. Recently it has acquired much reputation in these complaints, in consequence of its extensive and successful use in the hospitals of Paris. M. Bazin has employed it with success in psora, lichen agrius, the different scaly affections, the advanced stage of eczema, and favus. In most of these complaints we have long been in the habit of employing common tar ointment, and with probably equal success. A kind of soap is prepared from the oil of cade, which affords a convenient method of applying it. In the *Ed. Monthly Journ. of Med. Sci.* for July, 1852 (*page* 66), it is stated that the soap is made by distilling the tar, incorporating the volatile oil thus obtained with a fixed oil, and then saponifying this with soda. It is in the form of black balls, which readily unite with water, and may be applied to the surface like any other soap. The best plan is probably to apply it at bedtime, and wash it off next morning.

OIL OF EUPHORBIA. A fixed oil, obtained from the seeds of *Euphorbia Lathyris*, a biennial plant growing wild in this country, though believed to have been introduced from Europe. It is often found near gardens and in cultivated fields, and is generally called *mole plant*, under the impression that moles avoid the grounds where it grows. (*Pursh.*) It is the *Caper plant* of England. (*Loudon's Encyc. of Plants.*) Like the other species of Euphorbia, it contains a milky juice, which is extremely acrid; and the whole plant possesses the properties of a drastic purge; but the oil of the seeds is the only part used in

regular practice. This may be extracted by expression, or by the agency of alcohol or of ether. In the first case, the bruised seeds are pressed in a canvass or linen bag, and the oil which escapes is purified by decanting it from the whitish flocculent matter which it deposits upon standing, and by subsequent filtration. By the latter process, the bruised seeds are digested in alcohol or macerated in ether, and the oil is obtained by filtering and evaporating the solution. According to Soubeiran, however, the oils obtained by these different processes are not identical. That procured by expression is probably the purest.

Oil of euphorbia is colourless, inodorous, and, when recent, nearly insipid; but it speedily becomes rancid, and acquires a dangerous acrimony. Soubeiran has ascertained that it has a complex composition, containing, besides the pure oil, four distinct proximate principles. (*Journ. de Pharm.*, xxi. 259.) From 40 to 44 parts are obtained by expression from 100 of the seed.

This oil is a powerful purge, operating with much activity in a dose varying from five to ten drops. It was, some years since, much used by certain Italian and French physicians, who did not find it to produce inconvenient irritation of the stomach and bowels. Its want of taste, and the smallness of the dose, recommended it especially in the cases of infants. It was said to be less acrid and irritating than the croton oil, over which it also had the advantage of greater cheapness. Some trials which have been made with it on this side of the Atlantic have not tended to confirm these favourable reports. It was found uncertain in its cathartic effect, and very liable to vomit. (Scattergood, *Journ. of the Phil. Col. of Pharm.*, iv. 124.) It may be given in pill with the crumb of bread, or in emulsion.

OIL OF JASMINE. This oil is obtained from the flowers of *Jasminum officinale* or *common white jasmine*, and from those also of *J. Sambac* and *J. grandiflorum*. Alternate layers of the fresh flowers, and of cotton saturated with *oil of ben* (see *page* 1370), or perhaps other fixed oil, are exposed in a covered vessel to the warmth of the sun; the flowers being occasionally renewed till the oil becomes impregnated with their odour, when it is separated from the cotton by pressure. This method is necessary, as the flowers do not yield their aroma by distillation. The oil of jasmine is used only as a perfume.

OLIBANUM. Olibanum, the *frankincense* of the ancients, was erroneously ascribed by Linnæus to *Juniperus Lycia*. There appear to be two varieties of olibanum, one derived from the countries bordering on the Red Sea, and taken to Europe by way of the Mediterranean, the other brought directly from Calcutta. The tree producing the former has not been botanically described, though believed by some writers to be a species of Amyris. Captain Kempthorne, of the E. India Company's Navy, saw it growing upon the mountains, on the African coast, between Bunder Maryah and Cape Guardafui. According to his statement, it grows upon the bare marble rocks composing the hills in that region, without any soil or the slightest fissure to support it, adhering by means of a substance thrown out from the base of the stem. This rises forty feet, and sends forth near the summit short branches, covered with a bright green, singular foliage. The juice, which exudes through deep incisions made into the inner bark, is at first of the colour and consistence of milk, but hardens on exposure. (*Pharm. Journ. and Trans.*, iv. 37.) The India olibanum has been satisfactorily ascertained to be the product of the *Boswellia serrata* of Roxburgh, a large tree growing in the mountains of India, and found by Mr. Colebrook abundant in the vicinity of Nagpur. The tree belongs to the class and order *Decandria Monogynia*, and to the natural order *Terebintaceæ* of Kunth.

The Arabian or African frankincense is in the form of yellowish tears, and irregular reddish lumps or fragments. The tears are generally small, oblong or roundish, not very brittle, with a dull and waxy fracture, softening in the mouth, and bearing much resemblance to mastich, from which, however, they differ in their want of transparency. The reddish masses soften in the hand, have a stronger smell and taste than the tears, and are often mixed with fragments of bark, and small crystals of carbonate of lime.

The Indian frankincense, or olibanum, consists chiefly of yellowish, somewhat translucent, roundish tears, larger than those of the African, and generally covered with a whitish powder produced by friction. It has a balsamic resinous smell, and an acrid, bitterish, somewhat aromatic taste. When chewed it softens in the mouth, adheres to the teeth, and partially dissolves in the saliva, which it renders milky. It burns with a brilliant flame, and a fragrant odour. Triturated with water it forms a milky imperfect solution. Alcohol dissolves nearly three-fourths of it, and the tincture is transparent. From 100 parts, Braconnot obtained 8 parts of volatile oil, 56 of resin, 30 of gum, and 5·2 of a glutinous matter insoluble in water or alcohol, with 0·8 loss. Various saline substances were found in its ashes. The oil may be separated by distillation, and resembles that of lemons in colour and smell.

Medical Properties. Olibanum is stimulant like the other gum-resins; but is now never

used internally. It is chiefly employed for fumigations, and enters into the composition of some unofficinal plasters.

ONION. *Cepa.* The bulb of *Allium Cepa.* This is a perennial bulbous plant, with a naked scape, swelling towards the base, exceeding the leaves in length, and terminating in a simple umbel of white flowers. The leaves are hollow, cylindrical, and pointed. The original country of the onion is unknown. The plant has been cultivated from time immemorial, and is now diffused over the whole civilized world. All parts of it have a peculiar pungent odour, but the bulb only is used. This is of various size and shape, ovate, spherical, or flattened, composed of concentric fleshy and succulent layers, and covered with dry membranous coats, which are reddish, yellowish, or white, according to the variety. It has, in a high degree, the characteristic odour of the plant, with a sweetish and acrid taste. Fourcroy and Vauquelin obtained from it a white acrid volatile oil holding sulphur in solution, albumen, much uncrystallizable sugar and mucilage, phosphoric acid both free and combined with lime, acetic acid, citrate of lime, and lignin. The expressed juice is susceptible of the vinous fermentation.

The onion is stimulant, diuretic, expectorant, and rubefacient. Taken moderately, it increases the appetite and promotes digestion, and is much used as a condiment; but in large quantities it is apt to cause flatulence, gastric uneasiness, and febrile excitement. The juice is occasionally given, made into syrup with sugar, in infantile catarrhs and croup, in the absence of much inflammatory action. It is also recommended in dropsy and calculous disorders. Deprived of its essential oil by boiling, the onion becomes a mild esculent; and it is much more used as food than as medicine. Roasted and split, it is sometimes applied as an emollient cataplasm to suppurating tumours.

OPOPANAX. The concrete juice of *Pastinaca Opopanax* (Willd.), *Opopanax Chironium* (De Candolle). This species of parsnep, usually called *rough parsnep*, has a thick, yellow, fleshy, perennial root, which sends up annually a strong branching stem, rough near the base, about as thick as a man's thumb, and from four to eight feet in height. The leaves are variously pinnate, with long sheathing petioles, and large, oblong, serrate leaflets, of which the terminal one is cordate, others are deficient at their base upon the upper side, and the whole are hairy on their under surface. The flowers are small, yellow, and form large flat umbels at the termination of the branches. The plant is a native of the Levant, and grows wild in the South of France, Italy, and Greece. When the base of the stem is wounded, a juice exudes, which, when dried in the sun, constitutes the opopanax of commerce. Some authors state that it is obtained from the root. A warm climate appears necessary for the perfection of the juice; as that which has been collected from the plant in France, though similar to opopanax, is of inferior quality. The drug is brought from Turkey. It is said to come also from the East Indies; but Ainslie states that he never met with it in any Indian medicine bazaar.

It is sometimes in tears, but usually in irregular lumps or fragments, of a reddish-yellow colour, speckled with white on the outside, paler within, and, when broken, exhibiting white pieces intermingled with the mass. Its odour is strong, peculiar, and unpleasant; its taste bitter and acrid. Its sp. gr. is 1·622. It is inflammable, burning with a bright flame. In chemical constitution it is a gum-resin, with an admixture of other ingredients in small proportion. The results of its analysis by Pelletier were from 100 parts, 33·4 of gum, 42 of resin, 4·2 of starch, 1·6 of extractive, 0·3 of wax, 2·8 of malic acid, 9·8 of lignin, 5·9 of volatile oil and loss, with traces of caoutchouc. Water by trituration dissolves about one-half of the gum-resin, forming an opaque milky solution, which deposits resinous matter on standing, and becomes yellowish. Both alcohol and water distilled from it retain its flavour; but only a very minute proportion of oil can be obtained in a separate state.

Opopanax was formerly employed, as an antispasmodic and deobstruent, in hypochondriasis, hysteria, asthma, and chronic visceral affections, and as an emmenagogue in suppression of the menses; but it is now generally regarded as a medicine of very feeble powers, and in this country is scarcely ever used. The dose is from ten to thirty grains.

ORANGE RED. *Orange Mineral. Sandix.* Red oxide of lead, prepared by calcining carbonate of lead. It is of a brighter colour than *minium*, and is used as a pigment.

OROBANCHE VIRGINIANA. *Epifagus Americanus.* Nuttall. *Beech-drops. Cancer-root.* This is a parasitic, fleshy plant, with a tuberous, scaly root, and a smooth stem, branched from the base, from twelve to eighteen inches high, furnished with small ovate scales, of a yellowish or purplish colour, and wholly destitute of verdure. It is found in all parts of North America, growing upon the roots of the beech tree, from which it obtained its popular name. Is is in some places very abundant. The plant has a bitter, nauseous, astringent taste, which is said to be diminished by drying. It has been given internally in bowel affections; but its credit depends mainly upon the idea that it is useful

in obstinate ulcers of a cancerous character, to which it is directly applied in the state of powder. The late Professor Barton conjectured that it was an ingredient of a secret remedy, at one time famous as *Martin's cancer powder*, of which, however, the most active constituent was arsenious acid.

Other species of Orobanche, growing in America and Europe, have been employed. They are all parasitic, fleshy plants, without verdure, and of a bitter, nauseous taste. In Europe they are called *broom-rape*. The *O. Americana* and *O. uniflora*, of this country, are said to be used for the same purposes as the species above noticed, and like it are called *cancer-root*.

ORPIMENT. *King's Yellow.* A native tersulphuret of arsenic, consisting of one eq. of metal 75 and three eqs. of sulphur 48 = 123. It is in masses of a brilliant lemon-yellow colour, composed of flexible laminæ, and slightly translucent. It exists in various parts of the world, but is obtained for use from Persia and China. (*Guibourt.*) It is sometimes mixed with realgar, which gives it a reddish or orange hue. A similar sulphuret may be made artificially by passing sulphuretted hydrogen through a solution of arsenious acid in muriatic acid. There is reason to believe that neither the native sulphuret, nor the artificial, when prepared in the manner just mentioned and well washed, is poisonous; at least in a degree at all comparable to other arsenical compounds.

Artificial orpiment is prepared for use by fusing together equal parts of arsenious acid and sulphur. (*Turner.*) In Germany, according to Guibourt, it is prepared by subliming a mixture of these two substances. In this case, however, it retains a large portion of the acid undecomposed, and is therefore highly poisonous. Guibourt found a specimen which he examined to contain 94 per cent. of arsenious acid, and only 6 per cent. of the sulphuret of arsenic.

Orpiment is an ingredient of certain depilatories. *Atkinson's depilatory* is said to consist of one part of orpiment and six parts of quicklime, with some flour and a yellow colouring matter. (*Ann. der Pharm.*, xxxiii. 348.) But this arsenical sulphuret is chiefly used in fireworks, and as a pigment.

ORYZA SATIVA. *Rice.* This is an annual plant, originally, perhaps, derived from the East Indies, but now cultivated in all parts of the globe where the climate and soil are adapted to its growth. The rice of commerce consists of the seeds of the plant deprived of their husk. Carolina rice was found by Braconnot to contain 85·07 per cent. of starch, 3·60 of gluten, 0·71 of gum, 0·29 of uncrystallizable sugar, 0·13 of fixed oil, 4·80 of vegetable fibre, 5·00 of water, and 0·40 of saline substances. This grain is highly nutritious and of easy digestion, and constitutes the almost exclusive diet of whole nations. Being wholly free from laxative properties, it is admirably adapted to cases of weak bowels, in which there is a strong tendency to diarrhœa. Care, however, should be taken that it be boiled till it becomes soft. A decoction of rice, usually called *rice-water*, is a good nutritive drink in fevers, and inflammatory affections of the bowels, lungs, and kidneys. There appears to be no ground for the opinion, which has been entertained by some, that a diet of rice is injurious to the eyes.

OXALIC ACID. *Acidum Oxalicum.* This acid is found both in animals and vegetables. It is generated occasionally in consequence of a diseased action in the kidneys, and deposited in the bladder as oxalate of lime, forming a peculiar concretion, called from its appearance the *mulberry calculus*. In vegetables, it occurs in a free state in the bristles of the chick-pea (*Cicer arietinum*), combined with potassa as a supersalt in the *Rumex acetosa* or common sorrel, and the *Oxalis Acetosella* or wood-sorrel, and united with lime in several species of lichen, and in the roots of rhubarb, valerian, and several other plants. It is from the generic appellation *Oxalis*, that it takes its name.

Preparation. The usual process for obtaining oxalic acid consists in decomposing sugar by nitric acid. Four parts of sugar are acted upon by twenty-four of nitric acid of the sp. gr. 1·24, and the mixture is heated so long as any nitric oxide is disengaged. A part of the carbon of the sugar is converted into carbonic acid, by oxygen derived from the nitric acid, which is thereby partially converted into nitric oxide. The undecomposed nitric acid, reacting on the remaining elements of the sugar, generates oxalic and saccharic (oxalhydric) acids; the former of which crystallizes as the materials cool, while the latter remains in solution. The crystals being removed, a fresh crop may be obtained by further evaporation. The thick mother-water which now remains is a mixture of saccharic, nitric, and oxalic acids; and, by treating it with six times its weight of nitric acid, the greater part of the saccharic acid will be converted into oxalic acid. The new crop of crystals, however, will have a yellow colour, and contain a portion of nitric acid, the greater part of which may be got rid of by allowing them to effloresce in a warm place. From the experiments of Mr. L. Thompson, of Newcastle-on-Tyne, it appears probable that, in the reaction occurring between nitric acid and sugar, half the carbon of the latter is converted into carbonic acid, and the other half into oxalic acid.

The manufacturing chemists are said to obtain oxalic acid on a large scale by heating a mixture of 112 lbs. of sugar, 560 lbs. of nitrate of potassa, and 280 lbs. of sulphuric acid. The products are 135 lbs. of oxalic acid, and 490 lbs. of supersulphate of potassa, or *sal enixum*. (*L. Thompson.*)

Many substances, besides sugar, yield oxalic acid by the action of nitric acid; as for example molasses, rice, potato starch, gum wool, hair, silk, and many vegetable acids. In every case in which it is thus generated, the proportional excess of oxygen which it contains, compared with every other organic compound, is furnished by the nitric acid. When the acid is obtained from potato starch, this is first converted into starch sugar by the action of sulphuric acid. The following is an outline of the process, as conducted on a large scale. The pulp of potatoes, obtained by rasping or other suitable means, is washed two or three times by stirring it well with water, allowing it to subside, and running off the water. It is then boiled for some hours with water in wooden boilers, lined with lead and heated by steam; a quantity of sulphuric acid being stirred in the mixture, equal to two per cent. of the weight of the potatoes employed. By this treatment the starch of the potatoes is converted into starch sugar; and the change is known to be completed, when a drop of tincture of iodine, added to a little of the boiling liquor, placed on a piece of glass, ceases to produce a purple colour. The product is then filtered through a horse-hair cloth, and the liquid which passes is carefully evaporated until a gallon of it weighs about fourteen pounds. This liquid consists of a concentrated solution of starch sugar, and is now ready for conversion into oxalic acid by the action of nitric acid. For this purpose it is placed in wooden boilers, lined with lead, eight feet square and three deep, and, having been mixed with the requisite proportion of nitric acid, is heated to a temperature of about 125° F. by means of steam, passed through a coil of lead pipe, until the decomposition is effected. The liquor is then drawn off by a syphon or cock into shallow lead-lined wooden coolers to crystallize. The crystals having formed, the mother-waters are drawn off for use in a subsequent operation. When the manufacture of the acid is conducted in vessels of the size just indicated, the density of the nitric acid should not be less than 1·20 nor higher than 1·27. If the nitric acid be used of undue strength, a part of the oxalic acid at first formed becomes converted into carbonic acid, to the no small diminution of the desired product. (*Chem. Gaz.*, March 15, 1852, p. 112.) The product of oxalic acid from a given quantity of saccharine material has been much understated. If properly treated with nitric acid, 100 lbs. of good sugar will yield from 125 to 130 lbs. of oxalic acid, and the same weight of molasses, from 105 to 110 lbs.

Certain organic substances yield oxalic acid when heated with potassa. Thus shavings of wood, if mixed with a solution of caustic potassa, and exposed to a heat considerably higher than 212°, will be partially decomposed, and converted into oxalic acid, which then combines with the alkali.

Properties. Oxalic acid is a colourless crystallized solid, possessing considerable volatility, and a strong, sour taste. Its crystals have the shape of slender, flattened, four or six-sided prisms, with two-sided summits; and, when exposed to a very dry atmosphere, undergo a slight efflorescence. It dissolves in about nine times its weight of cold, and in its own weight of boiling water. The solution of the crystals takes place with slight crepitation. It dissolves also, but not to the same extent, in alcohol. The presence of nitric acid renders it more soluble in water. It combines with salifiable bases, and forms salts called oxalates. The most interesting of these are the three oxalates of potassa, severally called oxalate, binoxalate, and quadroxalate, and the oxalate of lime. The binoxalate and quadroxalate, both absurdly called *essential salt of lemons*, are employed for removing iron moulds from linen, and act by their excess of acid, which forms a soluble salt with the sesquioxide of iron constituting the stain. Oxalic acid is used for removing ink stains and iron moulds, for cleaning the leather of boot-tops, and for discharging colours in calico-printing.

This acid has a very strong affinity for lime, and forms with it an insoluble precipitate consisting of oxalate of lime, whenever the acid and earth are brought into contact in solution. Hence, oxalic acid and its soluble combinations are the best tests for lime; and, conversely, a soluble salt of lime for oxalic acid. When lime is searched for, oxalate of ammonia forms the most convenient test. So strong is the mutual attraction between this acid and lime, that the former takes the latter even from sulphuric acid. Hence, the addition of a soluble oxalate disturbs the transparency of a solution of sulphate of lime.

Oxalic acid is distinguished from all other acids by the form of its crystals, and by its solution yielding a precipitate with lime-water, insoluble in an excess of the acid.

Composition. Oxalic acid consists of two eqs. of carbon 12, and three of oxygen 24=36. When crystallized, three eqs. of water 27 must be added, making the eq. of the crystals 63. Two eqs. of this water may be driven off by a regulated heat, by which the acid is made to effloresce, but the third cannot be expelled without destroying the

acid itself. Accordingly, we have no knowledge of anhydrous oxalic acid in an uncombined state.

From the constitution of oxalic acid, as above given, it is plain that this acid corresponds in composition to carbonic acid and carbonic oxide taken together, and is, therefore, intermediate in the quantity of oxygen which it contains, between that acid and oxide. Notwithstanding that it contains less oxygen than carbonic acid, it is incomparably stronger as an acid, which circumstance may be accounted for by supposing some peculiarity in the mode in which its constituents are combined. The composition of the acid not only corresponds with the united constituents of carbonic acid and oxide, but there is reason to believe that these two compounds are actually its proximate constituents; for, if treated with strong sulphuric acid, the whole of the water will be abstracted, and the elements of the dry oxalic acid are instantly resolved into equal volumes of carbonic acid and carbonic oxide.

Oxalic acid combines with salifiable bases in two principal ways. Sometimes it drops its essential equivalent of water, which at other times it retains. Thus the oxalate of lead is a compound of the dry acid and the protoxide of lead; while the oxalate of lime retains one equivalent of water.

Medical and Toxicological Properties. Oxalic acid, in *small* doses, largely diluted with water and sweetened to the taste, forms an agreeable, cooling beverage, which may be used in febrile diseases as a substitute for lemonade. M. Nardo recommends it as an antiphlogistic and anodyne remedy in inflammation of the mucous membranes, given in the dose of a grain and a half dissolved in eight fluidounces of liquid. Notwithstanding the safety of its employment in medicinal doses, it is a virulent poison, producing death with great rapidity and certainty. Instances are on record of its proving fatal in ten minutes, and few survive the effects of a poisonous dose beyond an hour. As this acid is generally kept in the shops, and not a few instances are on record of its fatal effect, when taken by design, or by mistake for Epsom salt, we shall feel ourselves justified in being somewhat full on its toxicological relations.

Oxalic acid was first noticed as a poison by Mr. Royston in 1814; since which time it has been principally investigated in this relation by the late Dr. A. T. Thomson, of London, Dr. Percy, of Lausanne, Dr. Coindet, of Geneva, and Dr. Christison, of Edinburgh. Since its properties of certainty and rapidity as a poison have been more generally known, its employment for committing suicide has become more frequent.

From the general resemblance which the crystallized oxalic acid bears to Epsom salt, many fatal mistakes have occurred, in consequence of its being sold for that saline purgative. Nothing, however, can be easier than to distinguish them; for upon tasting a minute portion of the acid, which may be done with perfect safety, it will be found strongly sour, whereas the salt in question is bitter. Unfortunately, however, in the instances of these fatal mistakes, no suspicions being awakened, the solution is swallowed with haste, and the mischief is done before the victim is aware of his danger.

Oxalic acid acts on the economy in two principal ways, according as its solution is concentrated or dilute. When concentrated it causes exquisite pain, followed by violent efforts to vomit, then sudden dulness, languor, and great debility, and finally death without a struggle. When dilute it acts in a different manner. Dissolved in twenty times its weight of water, it possesses no corrosive and hardly any irritating power, and yet operates as a deadly poison, causing death by acting on the brain, spinal marrow, and heart. This statement, however, does not accord with the observations of Dr. Letheby, who asserts that the acid, whether in strong or weak solution, always exercises a corroding or softening power on the animal tissues.

The morbid appearances caused by oxalic acid are various. In a dissection reported by Dr. Christison, the mucous coat of the throat and gullet had an appearance as if scalded, and that of the gullet could be easily scraped off. The inner coat of the stomach was pultaceous, in many points black, in others red, and that of the intestines, similarly but less violently affected. In another case, recorded by the same author, the whole villous coat of the stomach was either softened or removed, as well as the inner membrane of the œsophagus; so that the muscular coat was exposed, and this coat exhibited a dark gangrenous appearance, being much thickened and highly injected. The stomach usually contains a dark fluid, resembling coffee-grounds, consisting chiefly of altered blood. In a few cases after death by this acid, no morbid appearances have been discovered.

In the treatment of poisoning by oxalic acid, the remedial measures must be employed with great promptitude. If the antidotes are not at hand, and vomiting is not free, emetics will be proper. The stomach pump would be useful, but no delay in the application of other remedies is admissible, in the expectation of its use. Dr. Christison objects to the use of warm water to promote vomiting, from a fear that it would increase the danger by promoting the absorption of the poison; but it may be a question whether this evil,

considering the incidental benefit of the water in promoting vomiting, is not less than that of the corrosion of the stomach, which copious dilution has a tendency to prevent. The proper antidote is chalk or magnesia, mixed with water; and as soon as either can be procured, it must be administered in large and frequently repeated doses. Chalk was first proposed for this purpose by Dr. A. T. Thomson. These substances act by neutralizing the poison, forming with it an insoluble oxalate of lime or magnesia, both of which are inert. The soluble salts of oxalic acid, as the oxalate of ammonia, and the oxalates of potassa, are likewise poisonous, and the antidotes for them are the same as for the acid.

The best tests for the detection of oxalic acid in the contents of the stomach, or in the vomited matter, in cases of suspected poisoning by this acid, are chloride of calcium, sulphate of copper, and nitrate of silver. The first causes a white precipitate of oxalate of lime, known by its being soluble in nitric acid; the second, a bluish-white precipitate of oxalate of copper; and the third, a dense white precipitate of oxalate of silver, which, when dried and heated, becomes brown and detonates faintly. When the antidotes have been freely used during life, the poison will be in the state of oxalate either of lime or magnesia. In this case, the oxalate found is to be boiled with a solution of carbonate of potassa, whereby an oxalate of potassa will be generated; and this must then be examined by the reagents above indicated.

OXALIS ACETOSELLA. *Wood-sorrel. Acetosella.* The wood-sorrel is a small, perennial, herbaceous, stemless plant, with numerous radical leaves, which are all ternate, and supported upon slender hairy petioles. The leaflets are obcordate, entire, hairy, of a yellowish-green colour, but frequently purplish on their under surface. The scape or flower-stalk, which usually exceeds the petioles in length, is furnished with two scaly bractes near the middle, and terminates in a large white, or flesh-coloured flower, marked with red streaks. The styles are of the same length with the inner stamens. This plant is a native both of Europe and North America. In this country it is found chiefly in the mountainous regions of the interior. It selects shady places, such as woods, groves, and hedges, and flowers in May. Other indigenous species of Oxalis, more widely diffused than the *O. Acetosella*, might be substituted for it without disadvantage; as they possess similar properties. They all have ternate leaves with obcordate leaflets, and, with the single exception of *O. violacea*, bear yellow flowers. The whole herbaceous portion may be used.

Wood-sorrel is without smell, and has an agreeable sour taste. It owes its acidity to *binoxalate of potassa*, which is sometimes separated for use, and sold under the name of *salt of sorrel*. This is prepared in Switzerland and Germany, from different species of Oxalis and Rumex, by the following process. The plants, previously bruised, are macerated for some days in water, and then submitted to pressure. The liquid thus obtained is mixed with clay, and occasionally agitated for two days. At the end of this time, the clear liquor is decanted, and evaporated so that crystals may form when it cools. These are purified by solution and a new crystallization. Five hundred parts of the plant afford four parts of the acidulous salt. The same salt may be prepared by exactly neutralizing with potassa one part of oxalic acid in solution, then adding one part more of the acid, and evaporating the solution so that it may crystallize upon cooling. Binoxalate of potassa is in rhomboidal crystals, of a sour, pungent, bitterish taste, soluble in forty parts of cold and six parts of boiling water (*Kane*), and unalterable in the air. It contains 72 parts or two equivalents of oxalic acid, 47·2 parts or one equivalent of potassa, and 18 parts or two equivalents of water. *Quadroxalate of potassa* is often substituted for the binoxalate. It is prepared in the same manner, except that, instead of one part, three parts of the acid are added to the original portion neutralized by potassa. Both salts are kept in the shops under the names of *salt of sorrel* and *essential salt of lemons*, and are employed for removing iron mould and ink stains from linen, and sometimes as a test for lime. Both are poisonous, though in a less degree than uncombined oxalic acid.

Medical Properties. This and other species of sorrel are refrigerant; and their infusion, or a whey made by boiling them in milk, may be used as a pleasant drink in febrile and inflammatory affections. A solution of the binoxalate of potassa is used, on the continent of Europe, as a substitute for lemonade. The fresh plant, eaten raw, is said to be useful in scorbutic cases. *Oxalis crassicaulis*, a Peruvian species, yields an edible root, and, by expression from its leaves, a very sour and astringent juice, which is employed in the form of syrup, in hemorrhages, chronic catarrh, bowel affections, and gonorrhœa, with asserted advantage.

OX-GALL. *Fel Bovinum.* The bile of the ox is a viscid fluid, of a green or greenish-yellow colour, a peculiar nauseous odour, and a bitter taste. The exact composition of bile is not yet settled. According to Berzelius, it contains, 1. *bilin*, 2. *cholepirrhin*, to which the bile owes its colour, 3. mucus, 4. extractive matters, 5. a peculiar fatty matter, originally found in biliary calculi, called *cholesterin*, 6. oleate, margarate, and stearate of soda, with

a little fatty matter not saponified, 7. chloride of sodium, sulphate, phosphate, and lactate of soda, and phosphate of lime. Of these substances, the most abundant and essential is *bilin*. This, when pure, is unerystallizable, colourless, translucent, inodorous, of an acrid and bitter taste with an after-taste of sweetness, inflammable, soluble in all proportions in water and anhydrous alcohol, insoluble in ether, neither alkaline nor acid, and composed partly of nitrogen. One of its most striking properties is the great facility with which it undergoes decomposition; and hence the numerous principles which different chemists have found in bile, many of which are nothing more than metamorphoses of bilin. Under the action of acids, it is changed into two resinous acids called respectively *fellinic acid* and *cholinic acid*, into *taurin*, and ammonia. The union of these two acids with a portion of bilin constitutes the choleïc acid of Demarçay. The colouring principle or *cholepyrrhin* is also readily changed, and gives rise to various new products, among which are *biliverdin*, a green colouring matter resulting from the absorption of oxygen, and *bilifulvin*, a yellow colouring matter, which is a double salt of lime and soda with a peculiar azotized acid. (*Journ. de Pharm.*, 3e *sér.*, iii. 177, from the *Journ. für praktische Chemie.*) E. A. Platner succeeded in separating the chief constituent of bile in a crystalline form, and considered it a compound of soda with a peculiar organic body. Liebig denominated this compound *bilate of soda*. The most recent analysis of bile that we have seen is that of A. Strecker, whose views differ essentially from those of Berzelius. According to Strecker, the bile of the ox, independently of the colouring, fatty, and saline matters above mentioned, consists essentially of a mixture of a nitrogenous acid free from sulphur, which he calls *cholic* acid, and a sulphuretted acid free from nitrogen. Both of these acids are combined with soda. The sulphuretted constituent undergoes decomposition with great facility, yielding a resin, taurin, and ammonia; so that it is with difficulty obtained separate. It is probably this constituent to which the picromel, biliary sugar, and bilin of other chemists may be referred. (*Chem. Gaz.*, A. D. 1848, pp. 154 and 155, from *Ann. der Chem. und Pharm.*)

Bile was formerly highly valued as a remedy in numerous complaints, and was considered peculiarly applicable to cases attended with deficient biliary secretion. It is supposed to be tonic and laxative. It is prepared for use by evaporating it to the consistence of an extract. The dose is from five to ten grains. *Refined ox-gall*, much used by limners and painters, is prepared, according to Gray, in the following manner. Take of "fresh ox-gall one pint; boil, skim, add one ounce of alum, and keep it on the fire for some time; to another pint, add one ounce of common salt in the same manner; keep them bottled up for three months, then decant off the clear; mix them in an equal proportion; a thick yellow coagulum is immediately formed, leaving the refined gall clear and colourless."

PÆONIA OFFICINALIS. *Peony.* This well known plant is a native of Southern Europe, but is everywhere cultivated in gardens for the beauty of its flowers. The root, flowers, and seeds were formerly officinal. The *root* consists of a caudex about as thick as the thumb, which descends several inches into the ground, and sends off in all directions spindle-shaped tubers, which gradually taper into thread-like fibres, by which they hang together. It has a strong, peculiar, disagreeable odour, and a nauseous taste, which is at first sweetish, and afterwards bitter and somewhat acrid. The odour disappears or is much diminished by drying. Peony-root was in very great repute among the ancients, who used it both as a charm and as a medicine in numerous complaints, particularly epilepsy. In modern times it has also been given in epilepsy and various nervous affections, but is at present seldom used. The dose of the fresh root is from two drachms to an ounce, boiled in a pint of water down to half a pint, which should be taken daily. It is said to be less active when dried. The expressed juice of the recent root is recommended in the dose of an ounce. It is milky, of a strong odour, and very disagreeable taste. The *flowers* are usually of a deep-red colour, though in some varieties of a light-red, and even whitish. They have, when fresh, an odour similar to that of the root, but feebler, and an astringent, sweetish, herbaceous taste. When dry they are inodorous. As a medicine they have little power, and are scarcely used. The *seeds* are roundish-oval, about as large as a pea, externally smooth, shining, and nearly black, internally whitish, inodorous when dry, and of a mild, oleaginous taste. By some authors they are said to be emetic and purgative, and by others are considered antispasmodic. They may be given in the same dose with the root, but are not used in regular practice.

PALM OIL. This highly valuable fixed oil is the product of *Elais Guiniensis*, a palm growing on the Western coast of Africa, and cultivated in the West Indies and South America. It is among the handsomest trees of its graceful family which flourish in the tropical regions of Africa. The oil is obtained by expression from the fruit. It is brought to this country chiefly from Liberia, and other places on the African coast, though prepared also in the West Indies, Cayenne, and Brazil. It is not improbable that various species of palms contribute to the supply of this article of commerce.

Palm oil has the consistence of butter, a rich, orange-yellow colour, a sweetish taste, and an agreeable odour, compared by some to that of violets, by others to that of the Florentine orris. By age and exposure it becomes rancid and of a whitish colour. It melts with the heat of the hand, and when perfectly fluid passes readily through blotting paper. Highly rectified alcohol dissolves it at common temperatures, and in ether it is soluble in all proportions. According to M. Henry, it consists of 31 parts of stearin and 69 of olein. But, from the experiments of Frémy and Stenhouse, it appears that the stearin has peculiar properties entitling it to be considered as a distinct principle, and it has accordingly received the name of *palmitin*. This is converted into *palmitic acid* by saponification. (*Kane's Chemistry.*) It appears also that a considerable proportion of this acid, together with some glycerin, exists uncombined in the oil, as ascertained by MM. Pelouze and Boudet; so that the changes which are effected in oils, through the agency of alkalies, in the process of saponification, take place, to a certain extent, spontaneously in palm oil. (*Journ. de Pharm.*, xxiv. 389.) Hence it is more easily saponified than any other fixed oil. It is said to be frequently imitated by a mixture of lard and suet, coloured with turmeric, and scented with Florentine orris. It is much employed in the manufacture of a toilet soap, which retains its pleasant odour. Palm oil is emollient, and has sometimes been employed in friction or embrocation, though not superior for this purpose to many other oleaginous substances.

PARIETARIA OFFICINALIS. *Wall Pellitory.* A perennial European herb, growing on old walls and heaps of rubbish. It is inodorous, has an herbaceous, somewhat rough and saline taste, and contains nitre derived from the walls where it flourishes. It is diuretic and refrigerant, and is said also, but without good reason, to be demulcent and emollient. The ancients employed it in various complaints, and it is still considerably used on the continent of Europe, especially in domestic practice. It is given in complaints of the urinary passages, dropsy, and febrile affections, usually in the form of decoction. The expressed juice is also used, and the fresh plant is applied in the shape of a cataplasm to painful tumours.

PARTHENIUM INTEGRIFOLIUM. *Prairie Dock.* This is an herbaceous perennial, growing abundantly in the prairies of our South-western States. It is recommended by Dr. Mason Houlton as a powerful antiperiodic. The flowering tops are the part used. They have an intensely bitter taste; and two ounces of them in the dried state, given in the form of infusion, are thought by Dr. Houlton to be equivalent to twenty grains of sulphate of quinia. Thirty successive cases of periodic fever were cured by this remedy, without any unpleasant effect on the nervous system. (*Med. Exam.*, N. S., ix. 719, from *Memphis Med. Recorder;* and *Pharm. Journ. and Trans.*, xii. 602, from *N. Y. Journ. of Pharm.*)

PATENT YELLOW. *Mineral Yellow.* A pigment, consisting of chloride combined with protoxide of lead. It is prepared by mixing common salt and litharge with a sufficient quantity of water, allowing the mixture to stand for some time, then washing out the liberated soda, and exposing the white residue to heat.

PAULLINIA. *Guarana.* This is a new medicine introduced into Europe from Brazil, which has attracted some attention from the asserted fact, that it contains a principle identical with caffein. The name of *paullinia* has been bestowed upon it from the generic title of the plant from which it is obtained. That of *guarana*, by which it was previously known, was derived from a tribe of aborigines, called Guaranis, who are said to use it extensively as a corrigent of their vegetable diet. It is prepared from the seeds of the *Paullinia sorbilis* of Martius, a climbing shrub, belonging to the class and order Octandria Trigynia of the Linnæan system, and the natural family of the Sapindaceæ. The seeds, which are contained in a three-celled, three-valved, coriaceous capsule, are lenticular and almost thorny, and invested with a flesh-coloured arillus which is easily separable when dry. They are prepared by powdering them in a mortar, or upon a chocolate stone previously heated, mixing the powder with a little water, exposing it for some time to the dew, then kneading it into a paste, mixing with this some of the seeds either whole or merely bruised, and finally forming the mixture into cylindrical or globular masses, which are dried and hardened in the sun, or by the smoke of a fire. These masses are of a reddish-brown colour, rugose on the surface, very hard, and of a marbled appearance when broken. Paullinia is of a somewhat astringent and bitterish taste, and in this as well as in its odour, bears some resemblance to chocolate, though not oleaginous. It swells up and softens in water, which partially dissolves it. Martius found in it a crystallizable principle, which he named *guaranin*, and which seems to have been proved by the researches of MM. Berthemot and Dechastelus to be identical with *caffein*. The discovery of caffein in four plants belonging to distinct natural families, namely, the coffee and tea plants, the Paraguay tea, and the Paullinia, is a highly interesting result of recent chemical investigations. It is said to be more abundant in the Paullinia than in either of the other vege-

tables. According to Berthemot and Dechastelus, it exists in the seeds united with tannic acid, with which it appears to form two compounds, one crystallizable and soluble in water, the other of a resinoid appearance and insoluble. Besides these ingredients, the seeds contain also free tannic acid, gum, albumen, starch, and a greenish fixed oil. (*Journ. de Pharm.*, xxvi. 514.)

The effects of paullinia upon the system are said to be those of a tonic: but they do not appear to have been very accurately investigated. It is highly probable, both from its composition and the use made of it by the natives of Brazil, that it has an influence over the nervous system similar to that of tea and coffee. It is habitually employed by the Indians, either mixed with articles of diet, as with cassava or chocolate, or in the form of drink prepared by scraping it and suspending the powder in sweetened water. It is considered by them useful in the prevention and cure of bowel complaints. Dr. Gavrelle, who was formerly physician to Don Pedro, in Brazil, and there became acquainted with the virtues of this medicine, called the attention of the profession to it some years since in France. He had found it advantageous in the diarrhœa of phthisis, sick-headache, paralysis, tedious convalescence, and generally as a tonic. By Dr. Ritchie, Surgeon in the British navy, it is highly recommended in irritation of the urinary passages. (*Ed. Month. Journ. of Med. Sci.*, N. S., v. 467.) It may be given in substance, in the quantity of one or two drachms, scraped into powder and mixed with sweetened water; but the most convenient form of administration is that of spirituous extract. According to M. Dechastelus, alcohol is the only agent which completely extracts its virtues; ether and water effecting this object but partially. Of the extract eight or ten grains may be given during the day in the form of pill. Paullinia may also be taken along with chocolate as a drink.

PEACH LEAVES. *Leaves of Amygdalus Persica.* (Willd. *Sp. Plant.* ii. 982.) *Persica vulgaris.* (Miller, Lamarck.) Every one is familiar with the appearance of the common peach tree. It is characterized specifically by having "all the serratures of the leaves acute, and by its sessile solitary flowers." Though its native country is not certainly known, it is generally supposed to have been brought originally from Persia. In no country, perhaps, does it attain greater perfection, as regards the character of its fruit, than in the United States. Peaches are among the most grateful and wholesome of our summer fruits. They abound in saccharine matter, which renders their juice susceptible of the vinous fermentation; and a distilled liquor prepared from them has been much used, in some parts of the country, under the name of peach brandy. The kernels of the fruit bear a close resemblance in appearance and properties, and probably in chemical nature, to bitter almonds, for which they are frequently, and without inconvenience, substituted in our shops. They are employed by distillers in the preparation of *liqueurs*, and by cake-bakers to give flavour to various productions of their ovens; and are said to yield as much amygdalin as bitter almonds. The flowers, leaves, and bark also have the peculiar odour and taste of bitter almonds, and yield hydrocyanic acid. The leaves afford a volatile oil by distillation. The distilled water prepared from them was found, in one instance, to contain 1·407 parts of hydrocyanic acid in 1000, and in another only 0·437 parts in the same quantity. From some experiments it may be inferred that the proportion of acid is greatest where there is the least fruit. (See *Am. Journ. of Pharm.*, xxiv. 172.)

Medical Properties. Peach leaves are said to be laxative; and they probably exert, to a moderate extent, a sedative influence over the nervous system. They have been used as an anthelmintic with great reported success. More recently their infusion has been recommended in irritability of the bladder, in sick stomach, and hooping cough. Half an ounce of the dried leaves may be infused in a pint of boiling water, and half a fluid-ounce given for a dose three times a day, or more frequently. Dr. Dougos gives, in hooping-cough, a pint of the strong infusion, in small doses, in the course of the day. (*Journ. de Pharm.*, xxiii. 356.) The flowers also are laxative; and a syrup prepared from them is considerably used, in infantile cases, upon the continent of Europe. Woodville states that a drachm of the dried flowers, or half an ounce in their recent state, given in infusion, is the dose as a vermifuge. Cases of fatal poisoning from their use in children are on record. The kernels have more of the peculiar powers of hydrocyanic acid, and therefore require to be used with some caution. Blanched, and rubbed up with hot water, they form an emulsion well adapted to coughs depending on or associated with nervous irritation. The bruised leaves, flowers, or kernels may be used by the apothecary for cleansing his vessels from disagreeable odours. (See *page* 92.) The dried fruit, stewed with sugar, is an excellent laxative article of diet, suitable to cases of convalescence attended with torpid bowels.

PHLORIDZIN. This is a bitter principle, discovered by Dr. Konink, of Germany, in the bark of the apple, pear, cherry, and plum trees. It is most abundant in the bark of

the root, and derived its name from this circumstance (from two Greek words, φλοιος bark, and ῥιζα a root). It is light, white, crystallizable in silky needles, of a bitter taste, soluble in about 1000 parts of cold and in all proportions in boiling water, very soluble in alcohol, scarcely soluble in ether cold or hot, dissolved without change by solutions of the alkalies, especially by ammonia, deprived of its water of crystallization at 212°, and fusible at a somewhat higher temperature. It is without acid or alkaline reaction, and consists of carbon, hydrogen, and oxygen; its formula being, according to G. Roser, when dry, $C_{42}H_{25}O_{20}$, with the addition of 4 eqs. of water when crystallized. When heated with dilute muriatic or sulphuric acid, it is converted into sugar and a peculiar substance called *phloretin*. (See *Chem. Gaz.*, viii. 392.) To obtain it, the fresh bark of the root of the apple tree should be selected, as the dried bark is said to contain it in much smaller proportion. The bark is to be boiled for an hour or two successively in two separate portions of water, each sufficient to cover it, and the decoctions set aside. At the end of thirty hours they will have deposited a considerable quantity of coloured phloridzin, which may be purified by boiling for a few minutes with distilled water and animal charcoal, filtering, repeating this process two or three times, and then allowing the solution to cool slowly. The phloridzin is deposited in the crystalline state. An additional quantity may be obtained by evaporating the decoction to one-fifth of its bulk, allowing it to cool, and purifying the substance deposited in the same manner as before.

Phloridzin is said to possess the anti-intermittent property in a high degree, and to have proved successful where quinia had failed. It was employed by Dr. Konink in the dose of ten or fifteen grains, and in this quantity effected cures in several cases of intermittent fever.

PHOSPHATE OF AMMONIA. *Ammoniæ Phosphas.* There are several phosphates of ammonia; but the one here described is the neutral tribasic phosphate, and consists of one eq. of phosphoric acid, two of oxide of ammonium, and one of basic water ($2NH_4O,HO,PO_5$). It may be made by saturating a somewhat concentrated solution of phosphoric acid with ammonia, applying heat, and setting the solution aside that crystals may form. (See *Acidum Phosphoricum Dilutum.*) Another method of forming it is to saturate the excess of acid in superphosphate of lime by means of carbonate of ammonia. Phosphate of lime is precipitated, and phosphate of ammonia obtained in solution, which, being duly concentrated by a gentle heat, affords the salt in crystals upon cooling. (See the paper of Mr. Charles Ellis on the mode of procuring this salt, in the *Am. Journ. of Pharm.*, xviii. 10.) The method of obtaining the superphosphate of lime is given at *page* 1186. Phosphate of ammonia is a white salt, crystallizing in rhombic prisms with dihedral summits, very soluble in water, but insoluble in alcohol. Exposed to the air it effloresces, loses ammonia, and becomes acid.

This salt was first brought under the notice of the profession, as a remedy for gout and rheumatism, by Dr. T. H. Buckler, of Baltimore, in a paper published in the *Am. Journal of the Medical Sciences*, for Jan. 1846. In this paper a number of cases are reported of these diseases, which were treated mainly by this remedy by Dr. Buckler and several of his medical friends, and with apparently good effects. Dr. Buckler was led to employ the salt on theoretical grounds. He conceives that the "matter of gout" consists of two salts, the urates of soda and lime, existing in the blood: and that the phosphate of ammonia, by reacting with them, would give rise to soluble salts. The new salts formed, if the double decomposition should take place, would be urate of ammonia, and the phosphates of soda and lime. Unfortunately for this theory, as furnishing the means of eliminating uric acid, urate of ammonia is not more soluble than urate of soda. Nevertheless, apart from all theory, the therapeutic powers of phosphate of ammonia deserve to be investigated. Since the publication of Dr. Buckler's paper, several practitioners, both in this country and in Europe, have used the remedy with apparently useful results. The dose of the salt is from ten to forty grains, three or four times a day, dissolved in a tablespoonful of water.

PHOSPHATE OF POTASSA. *Potassæ Phosphas.* The phosphate of potassa which has of late come into use as a medicine, is the neutral tribasic phosphate, having the formula, $2KO,HO,PO_5$, and, therefore, a composition precisely analogous to that of the medicinal phosphates of soda and ammonia. It is derived from the variety of phosphoric acid containing three eqs. of water, by the substitution of two eqs. of potassa for two of water, and is called *neutral* on account of its slight action on test paper, and to distinguish it from the *acid* tribasic phosphate, $KO,2HO,PO_5$, and the *alkaline*, $3KO,PO_5$. It may be formed precisely as phosphate of soda is prepared (see *page* 1186); or by saturating glacial phosphoric acid (HO,PO_5), changed by solution in water and ebullition into $3HO,PO_5$, by means of carbonate of potassa. The medicinal phosphate of potassa is a white, amorphous, deliquescent salt, incapable of crystallization. It has been given as an alterative in scrofula and phthisis, and in some other diseases, with supposed advantage.

The dose is from ten to thirty grains three times a day, dissolved in a tablespoonful of water.

PHYSALIS ALKEKENGI. *Alkekengi. Common Winter Cherry.* A perennial herbaceous plant, growing wild in the South of Europe, and cultivated in our gardens. The fruit is a round red berry, about as large as a cherry, enclosed in the calyx, and containing numerous flat kidney-shaped seeds. All parts of the plant are bitter, especially the leaves and the capsules enveloping the fruit. The berries are very juicy, and have an acidulous, bitterish taste. By drying they shrink, and become of a brownish-red colour. The bitter principle has been isolated by MM. Dessaignes and Chautard, and named by them *physalin*. It is obtained by agitating an infusion of the plant with chloroform, which extracts the bitter principle, and yields it by evaporation. To purify it, dissolve it in hot alcohol, add a little animal charcoal, filter, precipitate by water, and wash the precipitate with the same liquid. It is a light powder, white with a shade of yellow, of a taste slight at first, but in the end permanently bitter, very slightly soluble in cold water, somewhat more soluble in boiling water, and very soluble in alcohol and chloroform, especially with the aid of heat. It consists of carbon, hydrogen, and oxygen. (*Journ. de Pharm.*, *3e sér.*, xxi. 24.) The berries are said to be aperient and diuretic, and have been recommended in suppression of urine, gravel, and other complaints of the urinary passages. M. Gendron recommends them very highly as a febrifuge. He thinks they are most effective when allowed to ripen and begin to dry on the stem. He usually administers about three drachms daily in two doses. (*Arch. Gén.*, xxiii. 536.) From six to twelve berries, or an ounce of the expressed juice, may be taken for a dose; and much larger quantities are not injurious. They are consumed to a considerable extent in some parts of Europe as food. The berries of the *Physalis viscosa*, of this country, are said by Clayton to be remarkably diuretic.

PICHURIM BEANS. The seeds of an uncertain tree growing in Brazil, Guiana, Venezuela, and other parts of South America. The tree has been supposed to be the *Ocotea Pichurim* of Kunth (*Laurus Pichurim*, Richard, *Aydendron Laurel*, Nees); but this is positively denied by F. Nees von Esenbeck; and the brother of that botanist refers the seeds to *Nectandra Puchury*. The beans are the kernels of the fruit separated into halves. They are ovate-oblong or elliptical, flat on one side, convex on the other, of a grayish-brown colour externally, chocolate-coloured within, of an aromatic odour between that of nutmegs and sassafras, and of a spicy pungent taste. There are two kinds, one about an inch and a half long by half an inch in breadth, the other little more than half as large, rounder, and of a dark-brown colour. Their virtues depend on a volatile oil. In medical properties they resemble the common aromatics, and may be employed for the same purposes. They are rare in this country.

PIMPINELLA SAXIFRAGA. *Small Burnet Saxifrage. Saxifraga.* A perennial umbelliferous European plant, growing on sunny hills, and in dry meadows and pastures. The root is officinal in some parts of Europe. It has a strong, aromatic, yet unpleasant odour, and a sweetish, pungent, biting, aromatic, bitterish taste. Its active constituents are volatile oil, and an acrid resin. It is considered diaphoretic, diuretic, and stomachic; and has been used in chronic catarrh, asthma, dropsy, amenorrhœa, &c. The dose in substance is about half a drachm, and in infusion two drachms. The root is used also as a masticatory in toothache, as a gargle in palsy of the tongue and in collections of viscid mucus in the throat, and externally to remove freckles.

PINCKNEYA PUBENS. Michaux. A large shrub or small tree, growing in South Carolina, Georgia, and Florida, in low and moist places along the sea coast. It is closely allied, in botanical characters, to the Cinchonæ, with which it was formerly ranked by some botanists. The bark is bitter, and has been used with advantage in intermittent fever. Dr. Law, of Georgia, cured six out of seven cases in which he administered it. The dose and mode of preparation are the same with those of cinchona. The chemical composition and medical properties of this bark deserve a fuller investigation than they have yet received.

PISCIDIA ERYTHRINA. *Jamaica Dogwood.* Dr. William Hamilton, of Plymouth, England, in a communication to the *Pharmaceutical Journal and Transactions* (iv. 76, August, 1844), speaks of this plant as a powerful narcotic, capable of producing sleep and relieving pain in an extraordinary manner. He had noticed, when resident in the West Indies, the use of the bark of the root in the taking of fish, upon which, even when of a large size, it exercised a very strong narcotic effect. He was induced to try it as an anodyne in toothache, and found a saturated tincture exceedingly efficacious, not only affording relief when taken internally, but uniformly curing the pain when introduced upon a dossil of cotton into the carious tooth. The bark of the root, to be effectual, should be gathered during the period of inflorescence in April. When chewed it has an unpleasant acrimony like that of mezereon. It yields its virtues to alcohol but not to water. The formula employed by him in preparing the tincture, was to macerate an ounce of the bark, in

coarse powder, in four fluidounces of rectified spirit, for twenty-four hours, and then to filter. The dose is a fluidrachm. He first tried it on himself, when labouring under severe toothache, taking the quantity mentioned in cold water on going to bed. He first felt a violent sensation of heat internally, which gradually extended to the surface, and was followed by profuse perspiration, with profound sleep for twelve hours. On awaking, he was quite free from pain, and without the unpleasant sensations which follow a dose of opium.

PLANTAGO MAJOR. *Plantain.* A well known perennial herb, growing in fields, by the roadsides, and in grassplats, and abounding both in Europe and in this country. The leaves are saline, bitterish, and austere to the taste; the root saline and sweetish. The plant has been considered refrigerant, diuretic, deobstruent, and somewhat astringent. The ancients esteemed it highly, and employed it in visceral obstructions, hemorrhages, particularly from the lungs, consumption, dysentery, and other complaints. In modern times it has been applied to similar purposes, and the root is said to have proved useful in intermittents. At present, however, it is generally believed to be very feeble, and is little used internally. As an external application it has been recommended in ulcers of various kinds, and in indolent scrofulous tumours. Among the vulgar it is still much used as a vulnerary, and as a dressing for blisters and sores. The dose of the expressed juice is from one to four fluidounces. Two ounces of the fresh root or leaves may be boiled in a pint of water, and given during the day. Externally the leaves are applied whole or in decoction. *Plantago media*, and *P. lancifolia* or *rib-grass*, which are also indigenous, possess properties similar to those of P. major, and may be used for the same purposes.

Under the name of *semen psyllii*, the seeds of several species of Plantago, growing in different parts of Europe, are sometimes kept in the shops. The best are obtained from *Plantago Psyllium* or *fleawort*, which grows in the South of Europe and Barbary. They are small, about a line long by half a line in breadth, convex on one side, concave on the other, flea-coloured, shining, inodorous, and nearly tasteless, but very mucilaginous when chewed. They are demulcent and emollient, and may be used internally and externally in the same manner as flaxseed, which they closely resemble in medical properties.

PLATINUM. In 1826 Prof. Gmelin, of Tubingen, made experiments to determine the action of this metal on the economy. In 1841 Dr. Ferdinand Hoefer published some observations on the same subject. The latter experimented chiefly with the bichloride, and the double chloride of platinum and sodium. They are both poisonous: the bichloride in the dose of 15 grains, the double chloride in that of 30 grains. When a concentrated solution of the bichloride is applied to the skin, it produces violent itching, followed by an eruption. Administered internally it irritates the mucous membrane of the stomach, and occasions headache. The double chloride has no action when externally applied, and, when given internally, operates on the system in a less sensible manner than the bichloride. It possesses the power of augmenting the urine. Dr. Hoefer ranks the preparations of platinum with the alteratives, by the side of those of gold, iodine, and arsenic. He considers them particularly suited to the treatment of syphilitic diseases; the bichloride to cases of long standing and inveterate, the double chloride to those which are recent. The dose of the bichloride is from one to two grains twice a day, given in pill. Eight grains may be made into sixteen pills, with a drachm of the extract of guaiacum wood of the French Codex, and sufficient powdered liquorice root. Of these, one, two, or three may be taken morning and evening. The double chloride may be prepared for administration by dissolving five grains of the bichloride and eight of pure chloride of sodium in seven fluidounces of gum-water. This quantity may be taken by tablespoonfuls in the course of twenty-four hours. For frictions on indolent ulcers, Dr. Hoefer used an ointment composed of sixteen grains of the bichloride, thirty-two grains of extract of belladonna, and an ounce of lard. (*Journ. de Pharm.*, xxvii. 213.)

PLUMBAGO EUROPŒA. *Leadwort. Dentellaria.* A perennial, herbaceous plant, growing in the South of Europe. It has an acrid taste, and, when chewed, excites a flow of saliva. This is particularly the case with the root, which has been long used to relieve toothache. Hence the plant derived the name of *dentelaire*, by which it is known in France. A decoction of the root in olive oil has been highly recommended for the cure of the itch. Writers differ much in their statements in relation to the activity of the plant, some speaking of it as rubefacient, vesicatory, and caustic, and, when swallowed, as violently emetic and liable to produce dangerous irritation of the alimentary canal; while others consider it nearly inert. Perhaps the difference may be ascribed in part to the use of the plant in the recent state in one case, and dried or long kept in the other. A crystallizable, acrid principle, called *plumbagin*, has been extracted from the root by Dulong.

POLYPODIUM VULGARE. *Common Polypody.* A fern belonging both to the old and new continents, and growing in the clefts of old walls, rocks, and decayed trunks of trees.

The root, which is the part considered medicinal, is rather long, about as thick as a goose-quill, somewhat contorted, covered with brown, easily separable scales, furnished with slender radicles, and marked by numerous small tubercles. As found in the shops, it is sometimes destitute of the scales and radicles. Its colour is reddish-brown with a tinge of yellow, its odour disagreeably oleaginous, its taste peculiar, sweetish, somewhat bitter, and nauseous. The root of the variety growing upon the oak has been preferred, though without good reason. It was deemed purgative by the ancients, who employed it for the evacuation of bile and pituitous humours, in melancholic and maniacal cases. Modern physicians have used it in similar complaints, and as a pectoral in chronic catarrh and asthma. At present, however, it is scarcely ever employed, being considered nearly inert. It was given in doses varying from a drachm to an ounce, usually in connexion with cathartics.

POLYTRICHUM JUNIPERINUM. *Hair-cap Moss. Robbin's Rye.* This moss is a native of the United States, and abounds in New England. For a particular description of it, the reader is referred to a communication in the *Am. Journ. of Med. Sci.*, N. S. (xxvii. 267), by Dr. Wm. Wood, of East Windsor-Hill, Connecticut, who speaks in very strong terms of its efficacy as a diuretic, having found it the most successful remedy which he has employed in the treatment of dropsy. He infuses a large handful of the whole plant in water, and allows the patient to drink freely of the tea, "the more so the better."

POPULUS. *Poplar.* Several trees belonging to this genus have attracted some attention in a medical point of view. In most of them the leaf buds are covered with a resinous exudation, which has a peculiar, agreeable, balsamic odour, and a bitterish, balsamic, somewhat pungent taste. This is abundant in the buds of *Populus nigra* or the *black poplar* of Europe, which are officinal in some parts of that continent. They contain resin and a peculiar volatile oil. The buds of *P. balsamifera*, growing in the northern parts of N. America and Siberia, are also highly balsamic; and a resin is said to be furnished by the tree, which is sometimes, though erroneously, called *tacamahac*. The virtues of the poplar buds are probably analogous to those of the turpentines and balsams. They have been used in pectoral, nephritic, and rheumatic complaints, in the form of tincture; and a liniment, made by macerating them in oil, has been applied externally in local rheumatism. The *unguentum populeum* of European pharmacy is made, according to the directions of the French Codex of 1837, by bruising in a marble mortar, and boiling in 2000 parts of lard, with a gentle fire, till the moisture is dissipated, 250 parts, each, of the fresh leaves of the black poppy, deadly nightshade, henbane, and black nightshade; then adding of the dried buds of the black poplar, bruised, 375 parts; digesting for 24 hours; straining with strong expression; and finally allowing the ointment to cool after defecation. This is an anodyne ointment, occasionally employed in Europe in painful local affections. It has been ascertained that poplar buds are capable of imparting a principle to ointments, which in a considerable degree obviates their tendency to rancidity.

The bark of certain species of poplar is possessed of tonic properties, and has been used in intermittent fever with advantage. Such is the case with that of the *P. tremuloides* or *American aspen*, and of the *P. tremula* or *European aspen*. In the bark of the latter, Braconnot found *salicin*, and another crystallizable principle which he named *populin*. It is in these, probably, that the febrifuge properties of the bark reside. They may be obtained by precipitating a saturated decoction of the bark with solution of subacetate of lead, filtering, precipitating the excess of lead by sulphuric acid, again filtering, evaporating, adding animal charcoal towards the end of the evaporation, and filtering the liquor while hot. Salicin gradually separates, upon the cooling of the liquor, in the form of crystals. If, when this principle has ceased to crystallize, the excess of sulphuric acid in the liquid be saturated by a concentrated solution of carbonate of potassa, the populin will be precipitated. If this be pressed between folds of blotting paper, and redissolved in boiling water, it will be deposited, upon the cooling of the liquid, in the crystalline state. The leaves of *P. tremula* also afford populin, and more largely even than the bark. It is probable that both principles exist also in the bark of *P. tremuloides*, and other species. Salicin is described under *Salix*. *Populin* is very light, purely white, and of a bitter, sweetish taste, analogous to that of liquorice. When heated it melts into a colourless and transparent liquid. It is soluble in 2000 parts of cold, and about 70 parts of boiling water; and is more soluble in boiling alcohol. Acetic acid and the diluted mineral acids dissolve it, and, upon the addition of an alkali, let it fall unchanged. Piria regards it as a complex body, consisting of benzoic acid, saligenin, and glucose, and states that the effects of reagents on it correspond with this view of its constitution. By boiling it with solution of baryta, and precipitating the excess of baryta from the solution by carbonic acid, he found remaining in the solution only benzoate of baryta and salicin. (See *Am. Journ. of Pharm.*, xxiv. 240.)

PORTULACA OLERACEA. *Garden Purslane.* An annual succulent plant, growing in gardens and cultivated grounds in the United States, Europe, and most other parts of the

globe. It has an herbaceous, slightly saline taste, and is often used as greens, being boiled with meat, or other vegetables. It is considered a cooling diuretic, and is recommended in scurvy, and affections of the urinary passages. The seeds have been thought to be anthelmintic; but they are tasteless and inert.

POTENTILLA REPTANS. *Cinquefoil.* A perennial, creeping, European herb, with leaves which are usually quinate, and have thus given origin to the ordinary name of the plant. The root has a bitterish, styptic, slightly sweetish taste, and was formerly used in diarrhœa, and other complaints for which astringents are usually prescribed.

POWDER OF ALGAROTH. *Pulvis Algarothi. Oxychloride of Antimony. Nitromuriatic Oxide of Antimony.* This powder is formed by dissolving tersulphuret of antimony in muriatic acid, assisting the action, at first, by a gentle heat, which must be gradually increased to ebullition; and then pouring the resulting solution, when cold, into a large quantity of water. By a double decomposition between the tersulphuret and acid, sulphuretted hydrogen is given off copiously by effervescence, and a solution of terchloride of antimony is formed. When this is thrown into water, the greater part of the terchloride is converted, by the elements of that liquid, into muriatic acid which remains in solution, and teroxide of antimony, which precipitates in union with the remainder of the terchloride as the powder of Algaroth.

Properties, &c. This is a white powder, having a crystalline appearance if left long in contact with the solution from which it is precipitated. When exposed to a red heat, it fuses and forms a yellow liquid, which, on cooling, concretes into a grayish crystalline mass of a pearly aspect. It consists of nine eqs. of teroxide of antimony, and two of terchloride. It is used for making tartar emetic in the U. S. and Edinburgh Pharmacopœias, but without being recognised under a distinct name; being formed as the first step of the process adopted in those works, for preparing this antimonial. It was formerly officinal in the Dublin Pharmacopœia, and used for making the same antimonial; but in the last edition of that work, published in 1850, it was dismissed, and the pure teroxide substituted for it. (See *Antimonii Terchloridi Liquor* and *Antimonii Oxidum.*) Powder of Algaroth was formerly used in medicine; but, owing to its unequal operation, has been properly laid aside. It is liable to contain tersulphuret of arsenic (orpiment), unless when obtained from the distilled concrete terchloride of antimony. (Larocque, *Journ. de Pharm.*, March, 1849.)

PRENANTHES SERPENTARIA. *Lion's Foot.* This is a perennial indigenous herb, growing in the mountainous districts of Virginia and North Carolina. It belongs to *Syngenesia Æqualis* in the sexual system, and to the natural family of *Cichoraceæ*. The genus is characterized by its "four-flowered nodding *heads*, its cylindric *involucre* calyculate at the base, its subterate unbeaked *akenes*, its scabrous *pappus* in several series, and its naked *receptacle*." This particular species has rough dentate leaves, of which the radical are palmate, the cauline with long footstalks, sinuate pinnatifid, disposed to be three-lobed, with the middle lobe three-parted, the upper lanceolate. The racemes are terminal, somewhat panicled, short, and nodding, with an eight-cleft calyx, and twelve florets. (*Pursh.*) Dr. Darlington considers this a variety of *Prenanthes alba*. It is about two feet high, with purple flowers. Pursh speaks of it as in great repute among the inhabitants of the regions it inhabits as a remedy for the bite of poisonous serpents, and relates a case in which he had seen it used effectively. The milky juice of the plant was taken internally, and the leaves steeped in water were applied to the wound and frequently changed. In October, 1849, the author received a specimen of a plant from Dr. Newsom J. Pittman, of N. Carolina, with the information that he had employed it effectually in ten or twelve cases of the bite of the rattlesnake with uniform success. He gave internally a decoction of the root, which is extremely bitter. This plant was the Prenanthes Serpentaria of Pursh.

PRUNELLA VULGARIS. *Self-heal. Heal-all.* A small perennial labiate plant, common both in Europe and the United States, growing especially by the waysides. It is inodorous, but has an austere bitterish taste. The herb in flower was formerly used, in the state of infusion or decoction, in hemorrhages and diarrhœa, and as a gargle in sore-throat. In this country it is not employed in regular practice.

PULMONARIA OFFICINALIS. *Lungwort.* An herbaceous perennial, indigenous in Europe, and sometimes cultivated in this country in gardens. The leaves are inodorous, and have an herbaceous, somewhat mucilaginous, and feebly astringent taste. They have been considered pectoral and demulcent, and employed in catarrh, hæmoptysis, consumption, and other affections of the chest; but their virtues are doubtful, and they were probably used in pectoral complaints as much on account of the supposed resemblance of their speckled surface to that of the lungs, as from the possession of any positively useful properties.

PUMICE STONE. *Pumex.* A very light porous stone, found in the vicinity of active and extinct volcanoes, and believed to have been thrown up during their eruption. The pumice stone of commerce is said to be obtained chiefly from Lipari. It is used whole, in the manner of a file, for removing the outer surface of bodies, or for rubbing down inequalities, and, in the state of powder, for polishing glass, metals, stones, &c.; purposes to which it is adapted by the hardness of its particles.

PYRETHRUM PARTHENIUM. Willd. *Matricaria Parthenium.* Linn. *Chrysanthemum Parthenium.* Persoon. *Feverfew.* A perennial herbaceous plant, about two feet high, with an erect, branching stem, pinnate leaves, oblong, obtuse, gashed, and dentate leaflets, and compound flowers borne in a corymb upon branching peduncles. It is a native of Europe, but cultivated in our gardens. The whole herbaceous part is used. The plant has an odour and taste analogous to those of chamomile, which it resembles also in the appearance of its flowers, and in its medical virtues. Though little employed, it is undoubtedly possessed of useful tonic properties.

PYROACETIC SPIRIT. *Pyroacetic Ether. Acetone.* This substance may be obtained by carefully distilling acetate of lime, and rectifying the product by frequent distillations from quicklime in a water-bath, until the boiling point becomes stationary, whereby it is freed from water and empyreumatic oil. It is a colourless, volatile, inflammable liquid, having a peculiar penetrating smell, and a pungent taste like that of peppermint. Its specific gravity is 0·792, and boiling point 132°. As found in the shops its density is not generally lower than 0·820. It is miscible in all proportions with water, ether, and alcohol, without disturbing its transparency. If it become turbid when mixed with water, the fact shows that it contains empyreumatic oil. It has been confounded with pyroxylic spirit, from which it is distinguished by its inability to dissolve a saturated solution of chloride of calcium, which instantly dissolves in pyroxylic spirit. (*Scanlan.*) Its formula is C_3H_3O; while that of pyroxylic spirit is $C_2H_4O_2$. In constitution it bears considerable resemblance to alcohol. Thus its formula doubled is $C_6H_6O_2$, and that of alcohol is $C_4H_6O_2$. It was thought at one time that the substance brought to the notice of the profession by Dr. John Hastings, under the name of naphtha, as a remedy for pulmonary consumption, was pyroacetic spirit; but it now appears to be settled that what he intended was pyroxylic spirit. (See *Spiritus Pyroxilicus*, p. 701.) There is no doubt that these spirits were used indiscriminately in the therapeutic trials which grew out of the publication of Dr. Hastings's book; but no exact experiments have been made, so far as we know, to determine the precise physiological action of pyroacetic spirit.

REALGAR. This is the bisulphuret of arsenic, consisting of one eq of arsenic 75, and two of sulphur 32=107. It is found native in Saxony, Bohemia, Transylvania, and in various volcanic regions. Realgar is artificially made by melting arsenious acid with about half its weight of sulphur. (*Turner.*) Thus prepared, it is of a crystalline texture, of a beautiful ruby-red colour, of a uniform conchoidal fracture, somewhat transparent in thin layers, and capable of being sublimed without change. Native realgar is said to be innocent when taken internally, while that artificially prepared is poisonous, in consequence, according to Guibourt, of containing a little arsenious acid. Realgar is used only as a pigment.

RED CHALK. *Reddle.* A mineral substance of a deep-red colour, of a compact texture, dry to the touch, adhering to the tongue, about as hard as chalk, soiling the fingers when handled, and leaving a lively red trace when drawn over paper. It consists of clay and oxide of iron, and is intermediate between *bole* and *red ochre*, containing more oxide of iron than the former, and less than the latter. It is used for drawing lines upon wood, &c., and is sometimes made into crayons by levigating and elutriating it, then forming it into a paste with mucilage of gum Arabic, moulding this into cylinders, and drying it in the shade. It has been used internally as an absorbent and astringent.

RESEDA LUTEOLA. *Weld. Dyers' Weed.* An annual European plant, naturalized in the United States. It is inodorous, and has a bitter taste, which is very adhesive. Chevreul obtained from it by sublimation a peculiar yellow colouring matter, which he called *luteolin.* In medicine it has been employed as a diaphoretic and diuretic, but is now neglected. On the continent of Europe it is much employed for dyeing yellow, and, before the introduction of quercitron into England, was extensively applied to the same purpose in that country. The whole plant is used.

RHODODENDRUM CRYSANTHUM. *Yellow-flowered Rhododendron.* This is a beautiful evergreen shrub, about a foot high, with spreading branches, and oblong, obtuse, thick leaves, narrowed towards their footstalks, reflexed at the margin, much veined, rugged and deep-green upon their upper surface, ferruginous or glaucous beneath, and surrounding the branches upon strong petioles. The flowers are large, yellow, on long peduncles, and in terminal umbels. The corolla is wheel-shaped, with its border divided into five roundish,

spreading segments. The plant is a native of Siberia, delighting in mountainous situations, and flowering in June and July. The leaves are the part used. When fresh, they have a feeble odour, said to resemble that of rhubarb. In the dried state they are inodorous, but have an austere, astringent, bitterish taste. They yield their virtues to water and alcohol.

They are stimulant, narcotic, and diaphoretic, producing, when first taken, increase of heat and arterial action, subsequently a diminished frequency of the pulse, and, in large doses, vomiting, purging, and delirium. They have been long employed in Siberia as a remedy in rheumatism; and their use has extended to various parts of Europe. Their action is said to be accompanied with a sensation of creeping or pricking in the affected part, which subsides in a few hours, leaving the part free from pain. They have been recommended also in gout, lues venerea, and palsy. In Siberia they are prepared by infusing two drachms of the dried leaves in about ten ounces of water, in a close vessel, and keeping the liquid near the boiling point during the night. The strained liquor is taken in the morning; and a repetition of the dose three or four days successively generally effects a cure. The remedy is not used in this country.

RIGA BALSAM. *Balsamum Carpaticum. Balsamum Libani.* This is a product of the *Pinus Cembra*, a large tree growing in the mountainous regions and northern latitudes of Europe and Asia. The juice exudes from the extremities of the young twigs, and is collected in flasks suspended from them. It is a thin white fluid, having an odour analogous to that of juniper, and possessing the ordinary terebinthinate properties. In this country it is very rare; but it is occasionally brought from Riga or Cronstadt, in bottles. A similar product, called *Hungarian balsam*, is obtained in the same manner from the *Pinus Pumilio*, growing on the mountains of Switzerland, Austria, and Hungary. It is scarcely known in the United States.

ROTTEN STONE. *Terra Cariosa.* An earthy mineral, occurring in light, dull, friable masses, dry to the touch, of a very fine grain, and of an ash-brown colour. It is obtained from Derbyshire in England, and is used for polishing metals.

SALEP. Though not directed by any of the British Colleges, nor by our national Pharmacopœia, this substance deserves a slight notice, as it is frequently mentioned by writers on the materia medica, and is occasionally to be found in the shops. The name is given to the prepared bulbs of *Orchis mascula* and other species of the same genus. The *male orchis* is a native of Europe, the Levant, and northern Africa. Its bulbs, which are two in number, oval or roundish, internally white and spongy, are prepared by removing their epidermis, plunging them into boiling water, then stringing them together, and drying them in the sun or by the fire. By this process they acquire the appearance and consistence which distinguish them as found in the shops. Landerer, however, denies that as prepared in Greece or Macedonia they are dipped in boiling water, and ascribes their horny character to their being quickly dried in a baking oven. (*Pharm. Journ. and Trans.*, March, 1850.) They were formerly procured exclusively from Macedonia, Asia Minor, and Persia, but are now said to be prepared in France, and perhaps other parts of Western Europe.

Salep is in small, oval, irregular masses, hard, horny, semi-transparent, of a yellowish colour, a feeble odour, and a mild mucilaginous taste. It is sometimes kept in the state of powder. In composition and relation to water it is closely analogous to tragacanth, consisting of a substance insoluble, but swelling up in cold water (*bassorin*), of another in much smaller proportion, soluble in cold water, and of minute quantities of saline matters. It also occasionally contains a little starch. It is highly nutritive, and may be employed for the same purposes as tapioca, sago, &c. The reputation which it enjoyed among the ancients, and still enjoys in the East, of possessing aphrodisiac properties, is wholly without foundation. On account of its hardness, salep, in its ordinary state, is of difficult pulverization; but the difficulty is removed by macerating it in cold water until it becomes soft, and then rapidly drying it. Landerer states that it is sometimes used for adulterating Smyrna opium.

SANDARACH. *Sandaraca.* This is a resinous substance obtained from *Thuya articulata*, an evergreen tree growing in the North of Africa. It is in small, irregular, roundish oblong grains or tears, of a pale-yellow colour, sometimes inclining to brown, more or less transparent, dry and brittle, breaking into a powder under the teeth, of a faint agreeable odour increased by warmth, and of a resinous slightly acrid taste. It melts with heat, diffusing a strong balsamic odour, and easily inflames. It is almost entirely soluble in ordinary alcohol, and entirely so in that liquid when anhydrous, and in ether. Heated oil of turpentine also dissolves the greater part of it, but very slowly. According to Unverdorben, it consists of three different resins, varying in their relations to alcohol, ether, and the oil of turpentine. The *sandaracin* of Geise, which remains after sandarach has

been exposed to the action of ordinary alcohol, is a mixture of two of these resins. Sandarach was formerly given internally as a medicine, and enters into the composition of various ointments and plasters. At present it is used chiefly as a varnish. It is sometimes employed as incense, and its powder is rubbed upon paper in order to prevent ink from spreading, after letters have been scratched out.

SANICULA MARILANDICA. *Sanicle.* An indigenous, umbelliferous, perennial, herbaceous plant, two or three feet in height, growing in woods and thickets, in almost all parts of the United States, as far south as S. Carolina. For its botanical character see *Eaton's Botany*, and *Torrey and Gray's N. Am. Flora* (vol. i. p. 601). The root is the part used, and is popularly known in some parts of the country by the name of *black snakeroot*. It is fibrous and of an aromatic taste, and has been used as a domestic remedy in intermittent fever. Dr. J. B. Zabriskie has found it highly effectual in chorea. He considers it most efficient in substance, and gives the powder to children of eight or ten years old in the dose of half a drachm three times a day. (*Am. Journ. of Med. Sci.*, N. S., xii. 374.)

SANTALUM. *Sandal wood. Saunders.* There are three kinds of wood known by the name of santalum or saunders;—1. *santalum rubrum*, or red saunders, from Pterocarpus Santalinus, already described in this work (*page* 647) under the officinal name of *Santalum*: 2. *santalum album*, or *white saunders*, from the *Santalum album* of Linnæus, growing in the East Indies, the S. Pacific Islands, and South America; and 3. *santalum citrinum*, or *yellow saunders*, formerly supposed to be the inner wood of the tree of which the outer constituted white saunders, but now stated to be from a different tree, the *S. freycinetianum* of M. Gaudichaud, growing in the Sandwich Islands, the Fejee Islands, the Marquesas, on the coast of Malabar, &c. It is the latter which supplies the sandal wood so highly valued by the Chinese. Both kinds have a very agreeable aromatic odour. The white is thought by the East India physicians to be refreshing, and useful in remittent fevers, gonorrhœa, and other complaints. It was formerly used in European pharmacy, and still enters into certain compound syrups, confections, &c. The Chinese employ the yellow saunders chiefly as a perfume, burning it in their temples, sick chambers, &c., and obtain from it a volatile oil by distillation, which they mix with oil of roses. This variety was also formerly used in Europe, and praised as cordial and alexipharmic. The *three saunders* were not unfrequently combined in the same preparation. (*Merat and De Lens.*)

SAPONARIA OFFICINALIS. *Soapwort.* A perennial herbaceous plant, growing wild in this country, in the vicinity of cultivation, but probably introduced from Europe. It is commonly known by the vulgar name of *bouncing bet*. It is one or two feet high, with smooth, lanceolate leaves, and clusters of conspicuous whitish or slightly purplish flowers, which appear in July and August. The root and leaves are employed. They are inodorous, and of a taste at first bitterish and slightly sweetish, afterwards somewhat pungent, continuing long, and leaving a slight sense of numbness on the tongue. They impart to water the property of forming a lather when agitated, like a solution of soap, whence the name of the plant was derived. This property, as well as the medical virtues of the plant, resides in a peculiar proximate principle, obtained from the root by Bucholz, and called by him *saponin*. This principle constitutes, according to Bucholz, 34 per cent. of the dried root, which contains also a considerable quantity of gum and a little bassorin, resin, and altered extractive, besides lignin and water. Saponin is obtained, though not absolutely pure, by treating the watery extract with alcohol and evaporating. It is brown, somewhat translucent, hard and brittle, with a sweetish taste, followed by a sense of acrimony in the fauces. It is soluble in water and officinal alcohol, but is insoluble in anhydrous alcohol, ether, and the volatile oils. Its watery solution froths when agitated. This principle has been found also in various other plants, as different species of Silene, Dianthus, Lychnis, and Anagallis (*Journ. de Pharm.*, 3*e sér.*, x. 339.) It is said to possess poisonous properties. Soapwort has been much used in Germany as a remedy in venereal and scrofulous affections, cutaneous eruptions, and visceral obstructions. It appears to act as an alterative, like sarsaparilla, to which it has been deemed superior in efficacy by some physicians. The plant is given in the form of decoction and extract, which may be freely taken. From two to four pints of the decoction daily are recommended in lues. The inspissated juice, given in the quantity of half an ounce in the course of a day, is said by Andry generally to cure gonorrhœa in about two weeks, without any other remedy. According to Dr. Bonnet and M. Malapert, this and other plants containing saponin are capable of producing poisonous effects. (*Journ. de Pharm.*, 3*e sér.*, x. 339.)

SARCOCOLLA. A peculiar vegetable product, exuding spontaneously from the *Penæa Sarcocolla*, *P. mucronata*, and other species of Penæa, small shrubs growing at the Cape of Good Hope, in Ethiopia, Arabia, &c. It is in the form of small, roundish, irregular grains, sometimes agglutinated in masses, friable, opaque or semi-transparent, of a yel-

lowish or brownish-red colour, inodorous unless heated, when they have an agreeable smell, and of a peculiar, bitter, sweetish, and acrid taste. Sarcocolla, according to Pelletier, consists of 65·3 per cent. of a peculiar substance, considered by Dr. Thomson, as holding an intermediate place between gum and sugar, and called *sarcocollin* or pure sarcocolla, 4·6 of gum, 3·3 of a gelatinous matter having some analogy with bassorin, and 26·8 of lignin, &c. It is said to be purgative, but at the same time to produce serious inconvenience by its acrid properties. The Arabian physicians used it internally; and by the ancients it was employed as an external application to wounds and ulcers, under the idea that it possessed the property of agglutinating the flesh, whence its name was derived. It is at present out of use.

SARRACENIA. *Side-saddle Plant. Fly-trap.* Two southern species of this curious indigenous genus of plants, *S. flava* and *S. variolaris*, have been brought into notice by Dr. F. P. Porcher, in a communication published in the *Charleston Medical Journal and Review*. Dr. Porcher states that the roots of these plants have long been used as a domestic remedy by the inhabitants of the lower portions of South Carolina. The medicine is believed in that region to possess extraordinary powers in dyspepsia; and he received reports from persons entirely deserving of confidence, of its efficacy in sick headache, waterbrash, gastralgia, abdominal distension, &c. In trying the remedy upon himself, he found it to be bitter and astringent to the taste, and in its effects on the system, stimulant to the stomach, the circulation, and in some degree to the brain, and at the same time to a certain extent diuretic, and disposed to operate mildly on the bowels. From the results stated by Dr. Porcher, we should infer that the medicine is a stimulating tonic, with some tendency to act on the brain; and probably well suited to cases of dyspepsia dependent on debility of stomach. Professor Sheppard submitted the root to chemical examination, and found it to contain, lignin, colouring matter, resin, an acid salt of lime, and a salt probably of an organic alkali. The best mode of administration seems not to have been well determined. Invalids chew it as they would chew tobacco; and from Dr. Porcher's statements we should infer that it might be appropriately given in powder in the dose of half a drachm three or four times a day. (See *Wood's Quarterly Retrospect*, ii. 78.)

SASSA GUM. This name has been applied by Guibourt to a gum, occasionally brought into market from the East, and answering so exactly to Bruce's description of the product of a tree which he calls *sassa*, that there is reason to believe in their identity. According to Guibourt's description, it is in mammillary masses, or in convoluted pieces resembling an ammonite, of a reddish colour, and somewhat shining surface, and more transparent than tragacanth. Its taste is like that of tragacanth, but slightly acrid. When introduced into water, it becomes white, softens, and swells to four or five times its original bulk; but it preserves its shape, neither like tragacanth forming a mucilage, nor like Bassora gum separating into distinct flocculi. It is rendered blue by iodine.

SASSY BARK. This bark is interesting chiefly from its employment by the natives of Western Africa as an ordeal in their trials for witchcraft or sorcery. Specimens sent to this country from Liberia were first examined by Mr. C. A. Santos, who published his observations in the *Am. Journ. of Pharm.* (xxi. 97, April, 1849). Other specimens, both of the bark and of the plant producing it, afterwards came under the notice of Professor Procter, who was thus enabled to determine as well the chemical characters as the botanical source of the product. His papers on the subject are contained in the same Journal (xxiii. 301, and xxiv. 195); and in the last is given a botanical description of the tree. To these papers the reader is referred for particular information on the subject. It appears that the bark is the product of a previously undescribed species of *Erythrophleum*, for which Prof. Procter proposes the name of *E. judiciale*. It is a large tree with spreading branches, doubly pinnated leaves, flowers in spike-like racemes, and leguminous fruit. The bark is in pieces more or less curved, with or without epidermis, in the former case somewhat fissured externally, of a dull-red colour diversified by whitish spots, brittle, presenting when cut transversely numerous fawn-coloured spots surrounded by reddish-brown tissue, nearly inodorous, of an astringent taste, and according to M. Santos of the sp. gr. 1·054. Prof. Procter found it to contain tannic acid, insoluble apotheme analogous to that of rhatany, a red colouring matter formed by a combination of the two preceding constituents, gallic acid, gum, a little resin, fatty matter, various salts, and a peculiar substance precipitable by tannic acid, and soluble in alcohol and chloroform. He was unable to isolate the active principle. The bark yields its virtues to water. Its effects on the system have not been accurately studied; but it is certainly emetic and cathartic, and appears to superadd an influence over the nervous system, as it paralyzes muscular power. Professor Procter found three grains of the aqueous extract, given to a cat, to produce great prostration, frothing at the mouth, dilatation of the pupils, and total loss of inclination to eat. Largely taken the bark often causes death. The powder snuffed up the nostrils occasions violent sneezing.

SATUREJA HORTENSIS. *Summer Savory.* An annual labiate plant, growing spontaneously in the South of Europe, and cultivated in gardens as a culinary herb. It has an aromatic odour and taste, analogous to those of thyme, and was formerly used as a gentle carminative stimulant; but is now employed only to give flavour to food. The *S. montana*, or *winter savory*, which is also cultivated in gardens, has similar properties, and is similarly employed.

SCOLOPENDRIUM OFFICINARUM. Smith. *Asplenium Scolopendrium.* Linn. *Harts-tongue.* A fern indigenous in Europe and America. Its vulgar name was derived from the shape of its leaves, which were the part formerly used in medicine. They have a sweetish, mucilaginous, and slightly astringent taste, and, when rubbed, a disagreeable oily odour. They were used as a deobstruent in visceral affections, as an astringent in hemorrhages and fluxes, and as a demulcent in pectoral complaints; but their properties are feeble, and they have fallen into neglect.

SCROPHULARIA NODOSA. *Figwort.* The root of the *knotty rooted figwort* is perennial, tuberous, and knotty; the stem is herbaceous, erect, quadrangular, smooth, branching, and from two to three feet high; the leaves are opposite, petiolate, ovate-cordate, pointed, sharply toothed, veined, and of a deep-green colour; the flowers are small, dark-purple, slightly drooping, and borne on branching peduncles in erect terminal branches. The plant is a native of Europe, where it grows in shady and moist places, and flowers in July. The leaves, which are the part used, have when fresh a rank fetid odour, and a bitter somewhat acrid taste; but these properties are diminished by drying. Water extracts their virtues, forming a reddish infusion, which is blackened by the sulphate of the sesquioxide of iron. Figwort leaves are said to be anodyne and diuretic, and to have repellent properties when externally applied. They were formerly considered tonic, diaphoretic, discutient, anthelmintic, &c., and were thought to be useful in scrofula. They are at present very little employed, and never in this country. In Europe they are sometimes applied in the form of ointment or fomentation to piles, painful tumours and ulcers, and cutaneous eruptions.

SCUTELLARIA LATERIFLORA. *Scullcap.* This is an indigenous perennial herb, belonging to the Linnæan class and order *Didynamia Gymnospermia*, and to the natural order *Labiatæ*. Its stem is erect, much branched, quadrangular, smooth, and one or two feet high. The leaves are ovate, acute, dentate, subcordate upon the stem, opposite, and supported upon long petioles. The flowers are small, of a pale-blue colour, and disposed in long, lateral, leafy racemes. The calyx has an entire margin, which, after the corolla has fallen, is closed with a helmet-shaped lid. The tube of the corolla is elongated, the upper lip concave and entire, the lower three lobed. The plant grows in moist places, by the sides of ditches and ponds, in all parts of the Union. To the senses it does not indicate, by any peculiar taste or smell, the possession of medicinal virtues. It is even destitute of the aromatic properties which are found in many of the labiate plants. When taken internally, it produces no very obvious effects. Notwithstanding this apparent inertness, it obtained, at one period, extraordinary credit throughout the United States, as a preventive of hydrophobia, and was even thought to be useful in the disease itself. A strong infusion of the plant was given in the dose of a teacupful, repeated several times a day, and continued for three or four months after the bite was received; while the herb itself was applied to the wound. Strong testimony has been adduced in favour of its prophylactic powers; but it has already shared the fate, which in this case is no doubt deserved, of numerous other specifics against hydrophobia, which have been brought into temporary popularity, only to be speedily abandoned. Nevertheless, it is thought by some practitioners to have valuable therapeutic properties; and Drs. Ariel Hunton and C. H. Cleaveland, of Vermont, speak in strong terms of its efficacy as a nervine. They have employed it in neuralgic and convulsive affections, chorea, delirium tremens, and nervous exhaustion from fatigue or over-excitement, and have found it highly advantageous. Dr. Cleaveland says that he prefers it to all other nervines or other antispasmodics, except where an immediate effect is desirable. Dr. Cleaveland prefers the form of infusion, which he prepares by adding half an ounce of the dried leaves to a teacupful of water, and allows the patient to drink *ad libitum.* (*Am. Journ. of Pharm.*, xxiii. 370, from *N. Y. Register of Med. and Pharm.*, also *N. J. Med. Reporter*, v. 13.) The *Scutellaria galericulata*, or common *European scullcap*, which also grows wild in this country, has a feeble, somewhat alliaceous odour, and a bitterish taste. It has been employed in intermittents, and externally in old ulcers, but is now out of use. Dr. R. W. Evans, of Canada West, has found it useful in epilepsy; but to effect a cure it must be continued, he says, for five or six months. He makes an infusion with two ounces of the herb and eight ounces of water, and gives a fluidounce every eight hours, doubling the quantity after a week. (See *Am. Journ. of Med. Sci.*, xvii. 495.) Another indigenous species, the *S. integrifolia*, of which the *S. hyssopifo-*

lia, Linn., is considered by some as a variety, is intensely bitter, and might probably be found useful as a tonic.

SECALE CEREALE. *Rye.* Syria, Armenia, and the southern provinces of Russia have been severally indicated as the native country of rye. The plant is now cultivated in all temperate latitudes. The *grains* consist, according to Einhof, of 24·2 per cent. of envelope, 65·6 of flour, and 10·2 of water. The *flour*, according to the same chemist, consists of 61·07 per cent. of starch, 9·48 of gluten, 3·28 of albumen, 3·28 of uncrystallizable sugar, 11·09 of gum, 6·38 of vegetable fibre, besides 5·62 of loss, comprising an acid, the nature of which was not determined. Rye flour has been much used, in the dry state, as an external application to erysipelatous inflammation, and other eruptive affections, the burning and unpleasant tingling of which it tends to allay, while it absorbs the irritating secretions. In the form of mush it is an excellent laxative article of diet, and, mixed with molasses, may be given with great advantage in hemorrhoids and prolapsus ani, connected with constipation.

SEDUM ACRE. *Biting Stone crop. Small Houseleek.* A small, perennial, succulent European plant, growing on rocks and old walls, with stems about as long as the finger, and numerous very minute leaves. It is inodorous, and has a taste at first cooling and herbaceous, afterwards burning and durably acrid. Taken internally it vomits and purges, and applied to the skin, produces inflammation and vesication. The fresh herb and the expressed juice have been used as an antiscorbutic, emetic, cathartic, and diuretic, and have been applied locally to old ulcers, warts, and other excrescences; but the plant is at present little employed. It has recently been recommended in Germany as a remedy in epilepsy. Other species are less acrid, and are even eaten as salad in some parts of Europe. Such are the *Sedum rupestre* and *S. album*. *S. Telephium* was formerly employed externally to cicatrize wounds, and internally as an astringent in dysentery and hæmoptysis; and is still esteemed by the common people in France as a vulnerary.

SEMPERVIVUM TECTORUM. *Common Houseleek.* A perennial succulent European plant, growing on rocks, old walls, and the roofs of houses, and remarkable for its tenacity of life. It is occasionally cultivated in this country as an ornament to the walls of houses, or as a domestic medicine. The leaves, which are the part used, are oblong, pointed, from half an inch to two inches in length, thick, fleshy, succulent, flat on one side, somewhat convex on the other, smooth, of a light-green colour, inodorous, and of a cooling, slightly saline, astringent, and sourish taste. They are employed, in the recent state and bruised, as a cooling application to burns, stings of bees, hornets, &c., ulcers, and other external affections attended with inflammation. They contain a large proportion of supermalate of lime.

SENECIO VULGARIS. *Common Groundsel.* An annual European plant, introduced into this country, and growing in cultivated grounds. The whole herb is used, and should be gathered while in flower. It has, when rubbed, a peculiar rather unpleasant odour, and a disagreeable, herbaceous, bitterish, and saline taste, followed by a sense of acrimony. It is emetic in large doses, and has been given in convulsive affections, liver complaints, spitting of blood, &c., but is now very little used. The bruised herb is sometimes applied externally to painful swellings and ulcers. The plant is employed also as food for birds, which are fond of it. Other species of Senecio have also been medicinally used; and an indigenous species, the *S. aureus* or *ragwort*, is said by Schoepf to be a favourite vulnerary with the Indians.

SIENNA. *Terra di Sienna.* An argillaceous mineral, compact, of a fine texture, very light, smooth and glossy, of a yellowish-brown or coffee-colour, leaving a dull orange trace when moistened and drawn over paper. By calcination it assumes a reddish-brown colour, and is then called *burnt sienna*. In both the raw and burnt states it is used in painting. The best sienna is brought from Italy, but an inferior kind is found in England.

SILENE VIRGINICA. *Catchfly. Wild Pink.* An indigenous perennial plant, growing in Western Virginia and Carolina, and in the States beyond the Alleghany mountains. Dr. Barton, in his "Collections," states that a decoction of the roots is said to be efficacious as an anthelmintic. We are told that it is considered poisonous by some of the Indians. *S. Pennsylvanica*, which grows in the Eastern section of the Union, from New York to Virginia, probably possesses similar properties.

SISYMBRIUM OFFICINALE. Scopoli. *Erysimum officinale.* Linn. *Hedge Mustard.* A small annual plant, growing in the United States and Europe, along the roadsides, by walls and hedges, and on heaps of rubbish. It has an herbaceous somewhat acrid taste, which is strongest in the tops and flower-spikes, and resembles that of mustard, though much weaker. The seeds have considerable pungency. The herb is said to be diuretic

and expectorant, and has been recommended in chronic coughs, hoarseness, and ulceration of the mouth and fauces. The juice of the plant may be used mixed with honey or sugar, or the seeds may be taken in substance. *Sisymbrium Sophia*, or the *flix weed*, was formerly also officinal. It is of a pungent odour when rubbed, and of an acrid biting taste. The herb has been used externally in indolent ulcers, and the seeds internally in worms, calculous complaints, &c.

SIUM NODIFLORUM. *Water-parsnep.* A perennial, umbelliferous, aquatic European plant, growing also in the Southern section of the United States, where it is supposed to have been introduced. It is commonly considered poisonous; but the expressed juice, given by Withering in the dose of three or four ounces every morning, was not found to affect the head, stomach, or bowels. He found it, in this quantity, very advantageous in obstinate cutaneous diseases; and the plant has been usefully employed by others in similar complaints, and in scrofulous swellings of the lymphatic glands. It is considered diuretic. *Sium latifolium*, which grows in Europe and the United States, and is the *common water parsnep* of this country, is positively asserted to be poisonous; and madness and even death are said to have followed the use of the root. The *S. Sisarum* or *skirret*, a plant of Chinese origin, cultivated in Europe, has a sweetish, somewhat aromatic root, which is employed as food in the form of salad, and is supposed to be a useful diet in complaints of the chest.

SMALT. *Azure.* When the impure oxide of cobalt, obtained by roasting the native arseniuret of that metal, is heated with sand and potassa, the mixture melts, and a beautiful blue glass results, which, when reduced to powder, receives the name of smalt. It is used chiefly in painting.

SOOT. *Fuligo Ligni.* This well known substance has a peculiar smell, and a bitter, empyreumatic, and disagreeable taste. Its composition is very complex. Reduced to powder and treated with water, it affords an infusion of a deep-yellow or brown colour, the colour being deeper if heat be employed. The insoluble portion amounts to about forty-four per cent. The soluble part consists chiefly, according to Berzelius, of a pyrogenous resin united with acetic acid (*acid pyretin*), saturated with potassa, lime, and magnesia. It also contains sulphate of lime, chloride of potassium, acetate of ammonia, and traces of nitric acid. If the solution be evaporated to dryness, it furnishes a black extract. This forms with water a blackish-brown solution, which, when treated with any free acid except the acetic, lets fall the acid pyretin, in the form of a black mass resembling pitch; while the acid employed remains in solution with the bases previously in combination with the pyretin. Braconnot thought he had discovered in the pyretin a peculiar principle, to which he gave the name of *asbolin;* but Berzelius thinks he was mistaken. Besides these substances, Braconnot ascertained the existence in soot of an azotized extractive matter to the amount of twenty per cent. This matter, when submitted to dry distillation, afforded a considerable portion of pyrogenous oil. The soot itself, when subjected to a similar distillation, furnishes one-fifth of its weight of empyreumatic oil. To the above ingredients of soot must be added creasote, to the presence of which it is supposed to owe its medicinal properties.

Soot was formerly officinal with the Edinburgh College, and the Scotch physicians were in the habit of frequently prescribing it as a tonic and antispasmodic in the form of tincture. It went very much out of use in regular practice; and it is only within a few years, that its employment has been revived on account of its containing creasote. At present it is chiefly used as an external remedy in the form of decoction or ointment. In the *Revue Méd.* for June, 1834, M. Blaud details a number of cases of various affections, such as obstinate tetters, porrigo favosa, psora, fistula, cancerous and venereal ulcers, chronic irritations of the lining membrane of the mouth, exudations from the mucous membrane of the nose, herpetic eruptions of the genital organs, and pruritus of the vulva, in which the use of soot effected a cure. The *decoction* is made by adding two handfuls of soot to a pint of water, boiling for half an hour, and filtering. It is applied as a lotion to the affected parts, or injected into the fistulæ several times a day; and, in the intervals, the part, if accessible, is dressed with an *ointment*, made by rubbing up a drachm of finely powdered soot with an ounce of lard. In cases of porrigo, the crusts must be removed by poultices before the soot is applied. In scrofulous ophthalmia, M. Caron Duvillards and M. Baudelocque have found a collyrium, made according to the following formula, very useful. Infuse two ounces of soot in boiling water, filter the solution, and evaporate it to dryness. Dissolve the dry residue, with the assistance of heat, in strong white wine vinegar, and add extract of roses in the proportion of twenty-four grains to twelve fluidounces of the liquid. It is prepared for use by adding a few drops of the liquid to a glass of water. (*Bull. Gén. de Thérapeutique*, March, 1834.) This formula is not very satisfactory; as it does not indicate the proportion of vinegar to be employed. In a case of

severe and extensive burn, in which, after the separation of the sloughs, the patient began to sink from the profuse discharge, Dr. Ebers, of Bordeaux, found advantage from the application, to the granulating surface, of lint soaked in a decoction of soot. It reduced the discharge in a surprising manner, and promoted cicatrization.

The late Dr. Hewson, of this city, found an infusion of soot an efficacious remedy, employed by injection, in cases of ascarides. In one case of long standing in an adult, in which a number of remedies had been tried unsuccessfully, injections of soot daily, persevered in for two weeks, effected a complete cure. The injection was made by adding a cupful of soot to a pint of boiling water, and straining the solution. An *infusion of hickory ashes and soot* is used in this city as a popular remedy for dyspepsia. It is made by infusing a pint of clean hickory ashes and a gill of soot in half a gallon of boiling water, allowing the liquor to stand for twenty-four hours, and then decanting. Of this a small wineglassful is taken three or four times a day. No doubt this infusion has been useful in acidity of stomach; but its indiscriminate use in the various gastric affections popularly confounded under the name of dyspepsia, is calculated to do much harm.

Soot is decidedly antiseptic. A few shovelfuls of it, thrown into privies or drains, effectually destroy their foul exhalations.

SPANISH BROWN. A brownish-red ochre, much used in painting.

SPARTIUM JUNCEUM. *Spanish Broom.* A small shrub, indigenous in the South of Europe, and cultivated in our gardens as an ornamental plant. The flowers are large, yellow, and of an agreeable odour. The seeds are in moderate doses diuretic and tonic, in large doses emetic and cathartic, and have been used advantageously in dropsy. The dose is from ten to fifteen grains three times a day. They may also be given in tincture.

SUCCINIC ACID. *Acidum Succinicum.* This acid is obtained by distilling amber. (See *Succinum.*) The product is an aqueous solution of impure succinic acid, associated with empyreumatic oil. (See *Oleum Succini.*) By filtering the liquor the solution of the impure acid passes through, while the oil is absorbed by the paper. The acid may be purified by boiling the solution with nitric acid, diluted with twice its bulk of water, and then evaporating to crystallize. Should the crystals not be colourless, the treatment with nitric acid must be repeated until they are so. Succinic acid is formed artificially by the action of nitric acid on the fatty acids, and under various other circumstances. M. Desaignes obtained it from malate of lime, subjected to the influence of fermentation excited by casein. The malate was converted into the succinate of lime.

Succinic acid, when pure, is a white, transparent solid, crystallizing in prisms, and having a somewhat acrid taste. It dissolves in five times its weight of cold, and twice its weight of boiling water. It is soluble also in alcohol, but very sparingly so in ether. Nitric acid is without action on it. It melts at 365°, and boils without alteration at 473°. It sublimes, however, at a much lower temperature. According to Wackenroder it is sometimes adulterated with tartaric acid, soaked in oil of amber. Crystallized from its solution in water, its formula is $C_4H_2O_3+HO$. The sublimed acid has the formula $2C_4H_2O_3+HO$. Some chemists double the equivalent of this acid, and make its formula $C_8H_4O_6$.

Succinic acid is at present never used in medicine, and has been very properly omitted in the Dublin Pharmacopœia of 1850. It has lately been ascertained to be a product of vital action, having been detected by M. Heintz in the colourless liquid found in the hydatid cysts of the liver. (*Journ. de Pharm*, Sept, 1850. from *Pogg. Annalen.*) One of its salts, *succinate of ammonia*, has been used with great alleged success in delirium tremens. This salt is occasionally used as a precipitant of sesquioxide of iron.

SULPHATE OF ALUMINA. *Aluminæ Sulphas.* The salts of alumina have been ascertained by M. Gannal to be powerful preservatives of animal matter. Among these the sulphate is to be preferred, on account of its easy preparation and moderate price. It may be made by saturating dilute sulphuric acid with hydrated alumina, and evaporating. It may be prepared also by the process of MM. Huria and Brunel, which consists in exposing in an iron cylinder, sulphate of alumina and ammonia (ammoniacal alum), first dried to separate its water of crystallization, to a cherry-red heat. Sulphate of alumina remains in the cylinder, and the volatilized products are collected in water. The chief of these is sulphite of ammonia, which serves for the preparation of a fresh portion of alum, after having been changed into the sulphate by oxidation in the air. (*Chem. Gaz.*, Sept. 15, 1852, p. 359.) A solution of this salt was found by M. Gannal to be very effectual in preserving bodies for dissection, when injected into the blood-vessels. In the summer season the bodies were preserved fresh for twenty days or more; in the winter, for three months. For use in the winter, a quantity of the solution, sufficient for injecting one body, may be made by adding a pound, avoirdupois, of the salt to a quart of water; for use in warm weather, the solution must be stronger. This salt has been used extensively in the

Philadelphia Hospital, Blockley, at the suggestion of Dr. Dunglison, as an antiseptic and detergent application to ulcers, and with favourable results. Dr. Pennypacker reports several cases in which it proved useful. The strength of the solution employed varied from ʒijss to ʒiij of the salt to fʒvi of water, according to the state of the ulcer. Dr. G. Johnson, of Georgia, found the solution attended with the happiest effects, used as an injection in fetid discharges from the vagina. (*Med. Exam.*, vi. 63 and 112.) *Acetate of alumina* and *chloride of aluminium* (muriate of alumina) also possess antiseptic powers.

SULPHATE OF ALUMINA AND IRON. *Aluminæ et Ferri Sulphas.* This double salt has been brought forward by Sir James Murray, of Dublin, as an astringent, styptic, and vermifuge. The method which he gives for preparing it is not very clearly expressed; but it may be presumed to be formed by dissolving alumina and carbonate of iron, both recently precipitated, in sulphuric acid, and duly evaporating the solution. Sir James recommends it in the treatment of chronic dysentery, diarrhœa, fluor albus, and the colliquative sweats and diarrhœa which attend hectic fever and consumption. Externally he found it a powerful styptic, useful as a gargle in relaxation of the tonsils and uvula, and in salivation, as an injection in hemorrhages, and as a wash for foul and flabby ulcers. The dose for internal exhibition is from five to ten grains, dissolved in some aromatic water. This salt probably consists of tersulphate of alumina, combined with tersulphate of sesquioxide of iron. It is, therefore, not an alum. A true alum, using that term as the designation of a class, has the general formula, $M_2O_3,3SO_3+MO,SO_3+24HO$. In ordinary alum the sesquioxide is alumina, and the protoxide, potassa; but the latter may be replaced by protoxide of iron, so as to give an alum, having the formula, $Al_2O_3,3SO_3+FeO,SO_3+24HO$, which occurs native, forming one variety of *plumose alum*, and may be made artificially. But the alumina may be replaced by certain other sesquioxides, as by those of manganese, chromium, and iron, forming the alums commonly called manganese, chrome, and iron alum. The latter has recently come into notice as a medicine, and deserves a notice in this place; the information respecting it having come too late for insertion under *Alumen.*

Iron Alum. Potassio-sulphate of Sesquioxide of Iron. Double Sulphate of Sesquioxide of Iron and Potassa. ($Fe_2O_3,3SO_3+KO,SO_3+24HO$.) This alum is formed by first converting the sulphate of protoxide of iron by sulphuric acid, assisted by nitric acid, into the tersulphate of the sesquioxide, and then adding an equivalent quantity of sulphate of potassa. (See *page* 1001.) The solution is then treated with an excess of sulphuric acid, and sufficiently evaporated to form crystals on cooling. Iron alum is in the form of octohedral crystals, of a pale-violet colour, more soluble than common alum, and forming a solution having a reddish colour. It was brought to the notice of the Pharmaceutical Society of London, in Dec. 1853, by Mr. Lindsey Blyth, as a new remedy prescribed in St. Mary's Hospital of that city. Dr. Tyler Smith found it to be a more powerful astringent than common alum, but devoid of the stimulating effects of the other salts of iron. The ammonio-sulphate of sesquioxide of iron, in which the potassa is replaced by oxide of ammonium, has identical therapeutic effects. The dose of iron alum is the same as that of ordinary alum. (*Pharm. Journ. and Trans.*, Jan. 1854, p. 306.)

SULPHATE OF CADMIUM. *Cadmii Sulphas.* This salt may be formed by dissolving carbonate of cadmium in dilute sulphuric acid, or metallic cadmium in the same acid, assisted with a little nitric acid. It is a soluble, astringent, efflorescent salt, crystallizing in prisms, which resemble those of sulphate of zinc. It acts on the economy like that salt, but is considered tenfold more powerful. Besides its emetic property, it possesses, according to M. Grimaud, valuable powers as a remedy in syphilis, rheumatism, and gout. As yet it has been used almost exclusively as an astringent and stimulating remedy in diseases of the eyes. In specks and opacities of the cornea, it has been employed successfully by a number of European surgeons. It is used either in solution, in the proportion of from half a grain to four grains to the fluidounce of distilled water, or in the form of ointment, made by mixing two grains with four scruples of fresh lard. M. Fronmüller has employed it, with excellent results, in specks of the cornea, dissolved in rose water in the proportion of three grains to two fluidounces, associated with from half a fluidrachm to a fluidrachm and a half of wine of opium. (*Journ. de Pharm.*, March, 1851.)

SULPHATE OF NICKEL. *Niccoli Sulphas.* This salt is formed by dissolving carbonate of nickel in dilute sulphuric acid, concentrating the solution, and setting it aside to crystallize. The carbonate is procured by dissolving the impure arseniuret of nickel, sold under the name of *speiss*, coarsely powdered and mixed with half its weight of iron filings, in nitromuriatic acid. The solution is evaporated to dryness, and the residue treated with water, which takes up the impure chloride of nickel, and leaves the arsenic in the form of the insoluble arseniate of iron. The liquid is then acidulated with muriatic acid, treated with sulphuretted hydrogen in excess, which precipitates the copper, and,

after filtration, boiled with a little nitric acid, to sesquioxidize any remaining iron. The cold liquid, largely diluted with water, is next treated with a solution of bicarbonate of soda, gradually added, which throws down the iron in the state of sesquioxide. Lastly, the filtered solution, containing the chloride of nickel nearly pure, is boiled with carbonate of soda, which, by double decomposition, throws down a pale-green precipitate of carbonate of nickel. Sulphate of nickel is in the form of emerald-green prismatic crystals, efflorescent in the air, soluble in three parts of cold water, but insoluble in alcohol and in ether. It has a sweet and astringent taste. It consists of one eq. of sulphuric acid 40, one of protoxide of nickel 37·5, and seven of water 63 = 140·5. (NiO,SO_3+7HO.)

Prof. Simpson, of Edinburgh, has made some therapeutic trials with this salt, and found it to act as a gentle metallic tonic, like the preparations of iron, yet somewhat differently. He used it successfully in a case which he relates, of severe and obstinate periodic headache. The dose is from half a grain to a grain three times a day, given in the form of pill, or of simple solution. In large doses it is liable to produce nausea, especially if taken on an empty stomach. (See *Braithwaite's Retrospect*, xxvii. 446.)

SULPHITE OF SODA. *Sodæ Sulphis.* (NaO,SO_2+8HO.) This salt may be prepared by passing sulphurous acid into a solution of carbonate of soda, and evaporating out of contact of the air. It is in the form of transparent crystals, soluble in four parts of cold, and less than their weight of boiling water. Sulphite of soda has been used in cases of yeasty vomiting with remarkable success. The matter vomited in these cases has a yeasty appearance on the surface, and is generally found to contain, when examined by the microscope, two microscopic fungi, called sarcina ventriculi and torula cerevisiæ. The remedy was first used at the suggestion of Prof. Graham, of London, who supposed that the sulphurous acid, necessarily extricated from the salt in the stomach by the acid of the yeasty matter, would destroy the parasites. Dr. Dobie, of Edinburgh, has reported two cases of yeasty vomiting, occurring under his observation, in which the disease was immediately checked by the sulphite. In one of the cases the vomited matter contained an enormous quantity of the torula, without sarcina. (*Ed. Monthly Journ.*, xiv. 574.) The dose of sulphite of soda is a drachm three times a day. (See *Hyposulphite of Soda*, p. 1343.)

SULPHOCYANURET OF POTASSIUM. *Potassii Sulphocyanuretum.* This salt is prepared by fusing in an iron vessel, at a *low* red heat, a mixture of two parts of dried ferrocyanuret of potassium, and one part of flowers of sulphur. The mass, when cold, is dissolved in boiling water, and, to decompose some sulphocyanuret of iron, the solution is treated with carbonate of potassa, which throws down the iron as a carbonate, and gives rise to the formation of a fresh portion of sulphocyanuret of potassium. The whole is then boiled for a quarter of an hour, filtered to separate the precipitated iron, and evaporated that crystals may form. These are purified from carbonate of potassa by being dissolved in alcohol, which takes up the sulphocyanuret and leaves the carbonate. The alcoholic solution is then allowed to crystallize. Sulphocyanuret of potassium is in long, striated, anhydrous prisms, deliquescent in a moist atmosphere, very soluble in alcohol, and having a cooling, somewhat biting taste. It has been proposed as a medicine by Sœmmering, as a substitute for hydrocyanic acid and cyanuret of potassium, on the ground that it possesses the same therapeutic properties, without their inconveniences.

SULPHURET OF CALCIUM. *Calcii Sulphuretum. Hydrosulphate of Lime.* This compound is formed by passing sulphuretted hydrogen, so long as it is absorbed, through water holding lime in suspension. It is in the form of a paste of a greenish-gray colour, and exhaling a strong odour of sulphuretted hydrogen. It is used as a *depilatory*, and is applied in a layer on the part which is to be deprived of hair. At the end of fifteen minutes it is removed with a wet sponge, which at the same time detaches the hairs. On account of this preparation giving out sulphuretted hydrogen, it must not be applied near the mouth or nose.

SUMBUL. *Jatamansi. Musk-root.* Under the name of sumbul or jatamansi, a root has long been used in India, Persia, and other parts of the East, as a perfume, as incense in religious ceremonies, and medicinally. It is the product of an unknown plant, supposed to be umbelliferous, and, from the character of the root, to grow in low wet places. The plant is said to inhabit no part of British India, but the regions to the North and East of it, as Nepaul, Bootan, Bucharia, &c. The root is taken northward to Russia, and reaches the rest of Europe through St. Petersburg. The physicians of Moscow and St. Petersburg were the first to employ it on the Continent of Europe; Dr. Granville first introduced it to the notice of the profession in Great Britain and this country. It has recently also been imported into England from India, whither it was brought from a great distance in the interior.

The medicine comes in transverse sections, from two to four inches in diameter, and from an inch to an inch and a half in length, with a dusky, light-brown wrinkled epidermis,

and an interior porous structure consisting of coarse, irregular, easily separable fibres. The fresh cut surface of a transverse section presents, within the epidermis, an exterior white and spotted layer, and an inner yellow substance which forms the greater part of the root. Examined by means of a microscope it exhibits translucent points which probably represent starch granules. Sumbul has a strong odour, very much resembling that of musk, which it retains even when long kept. The taste, at first feebly sweetish, becomes after a time bitterish and balsamic, but not disagreeable; and a strong aroma is developed under mastication, diffusing itself with a sensation of warmth through the mouth and throat, and rendering the breath fragrant. This effect, however, is much diminished by time. That brought from India differs somewhat from the Russian, being of closer texture, more dense and firm, and of a reddish tint. (*Am. Journ. of Pharm.*, xxiv. 174, from *Pharm. Journ.*)

The root has been analyzed by Reinsch and other German chemists, and found to contain volatile oil, two balsamic resins, one soluble in alcohol, the other in ether, wax, gum, starch, a bitter substance soluble in water and alcohol, a crystallizable acid which Reinsch proposes to call *sumbulic acid*, and saline matter. The musk-like odour seems to be connected with the balsamic resins, and probably depends on some principle associated with them not yet isolated. The volatile oil yielded by distillation has a taste like that of peppermint.

The virtues of the drug appear to be those of a nervous stimulant. It is used by the Russian physicians in low fevers of a typhous character, and in asthenic cases of dysentery and diarrhœa. It has also been employed by them with asserted success in malignant cholera. The authors, on the occasion of a visit in the summer of 1853 to St. Petersburg, were informed by Dr. Thielmann, physician to the Hospital of St. Peter and St. Paul, that he depended mainly on this remedy in the treatment of delirium tremens, having found it superior in its composing influence over that complaint even to opium. Dr. Granville recommends it in gastric spasm, hysteria, chlorosis, amenorrhœa, dysmenorrhœa, palsy of the limbs, epilepsy, and other nervous disorders. Its real value, however, is yet to be ascertained. It is given in substance, infusion, decoction, and alcoholic and ethereal tincture. There seems to be no great precision in relation to the dose; but it is inferrible from the accounts of the drug, that it may be used very much as we use valerian. The facts above stated are taken chiefly from a pamphlet by Dr. A. B. Granville, published in London, A. D. 1850.

SUPPOSITORIES. *Suppositoria.* These are solid bodies intended to be introduced into the rectum, with the view either of evacuating the bowels by irritating the mucous membrane of the rectum, or of producing a specific effect on the neighbouring parts, or on the system at large. They fulfil the same indications as enemata, and are sometimes preferable from the facility of their application, and, when the object is to produce the peculiar effect of a medicine, from the smallness of their bulk, which facilitates retention. Their form may be cylindrical, conical, or spherical; the last being preferable when the bulk is small. They should be of such a consistence as to retain their shape, but so soft as to incur no risk of wounding the rectum. For laxative purposes the suppository may be from one to three inches long, and about as thick as a common candle. Soap is not unfrequently employed for this purpose. A piece of solidified molasses (molasses candy) is sometimes preferred. To increase the purgative effect, and at the same time act on the uterine function, aloes may be added to the soap. Mr. A. B. Taylor, of Philadelphia, recommends *cocoa butter* as the best excipient for solids administered by the rectum, having more exactly the requisite degree of consistence and fusibility than any combination of suet, spermaceti, wax, &c., that could be employed. (*Am. Journ. of Pharm.*, xxiv. 211.) Opium, or some one of its preparations, is very advantageously administered in the form of a suppository, in cases of irritation of the rectum, urinary passages, or genital apparatus. The other narcotics may be used in the same way; and indeed any other medicine, in reference to its effects on the system, provided the quantity be not too large, and the local effects not too irritant. The dose may in general be three times that of the medicine given by the mouth.

SWIETENIA FEBRIFUGA. A large tree growing in the East Indies. The bark is the part employed. It is smooth and red internally, rough and gray on the outer surface, of a feeble aromatic odour, and an astringent bitter taste. Water extracts its virtues by infusion or decoction. It is said to have been much used in India as a substitute for Peruvian bark, to which it is somewhat analogous in medical properties. The dose of the powder is from thirty grains to half a drachm. The watery extract has the virtues of the bark.

The *Swietenia Mahagoni* or *mahogany tree*, which grows in the West Indies and other parts of tropical America, has also a bitter astringent bark, which resembles that of the

S. febrifuga in virtues as well as in sensible properties. The wood of this tree is the mahogany so much used in ornamental wood-work. The bark of *S. Senegalensis* is used on the coast of Africa in the cure of intermittents; and M. Caventou has extracted an alkali from it, which has been suggested as a cheap substitute for quinia. (See *Am. Journ. of Med. Sci.*, N. S., xx. 168.)

SYMPHYTUM OFFICINALE. *Comfrey.* A perennial European plant, cultivated in our gardens for medical use. Its root, which is the part used, is spindle-shaped, branched, often more than an inch thick and a foot long, externally smooth and blackish, internally white, fleshy, and juicy. By drying it becomes wrinkled, of a firm horny consistence, and of a dark colour within. It is almost inodorous, and has a mucilaginous, feebly astringent taste. Among its constituents are mucilage in great abundance, and a small quantity of tannin. It was formerly highly esteemed as a vulnerary, but has lost its credit in this respect. Its virtues are chiefly those of a demulcent, and it may be advantageously used for all the purposes to which the marshmallow is applied. It is a very common ingredient in the domestic cough mixtures, employed in chronic catarrh, consumption, and other pectoral affections. The most convenient form of administration is that of decoction, which may be made either from the fresh or dried root. According to Lewis, comfrey root yields to water a larger proportion of mucilage than the root of Althæa.

SYRINGA VULGARIS. *Common Lilac.* The leaves and fruit of this common garden plant have a bitter and somewhat acrid taste, and have been used as a tonic and febrifuge. In some parts of France, they are said to be employed habitually by the country people in the cure of intermittent fever; and they were recommended by Cruveilhier in the treatment of that complaint. The fruit was examined by MM. Petroz and Robinet, who found a sweet and a bitter principle. The latter was afterwards obtained pure by M. Meillet, who gave it the name of *lilacin*. The green capsules, which yield it in largest proportion, are boiled in water, the decoction is concentrated, subacetate of lead is added, the liquor is evaporated to the consistence of syrup, magnesia is added in excess, and the whole is evaporated to dryness. The residuum is powdered, digested in water at 90° or 100°, and then treated with boiling alcohol and animal charcoal. The alcoholic solution, being filtered and concentrated, yields lilacin upon cooling. This principle, though not alkaline, is thought by M. Meillet to exist in the fruit combined with malic acid. It is crystallizable, bitter, and insoluble in water. (*Am. Journ. of Pharm.*, xiv. 139, from *Journ. de Pharm.*)

TACAMAHAC. *Tacamahaca.* The resinous substance, commonly known by this name, is supposed to be derived from the *Fagara octandra* of Linn. (*Elaphrium tomentosum*, Jacq., *Amyris tomentosum*, Spreng.), a tree of considerable size, growing in the island of Curaçoa, and in Venezuela. The juice exudes spontaneously, and hardens on exposure. As brought into the market, it is in irregularly shaped pieces of various sizes, some not larger than a mustard seed, others as much as an inch or two inches in diameter. The colour is usually light-yellowish or reddish-brown; but in the larger masses is more or less diversified. The pieces are in general translucent, though frequently covered with powder upon their surface, so as to render them apparently opaque. They are heavier than water, brittle, and pulverizable, yielding a pale-yellow powder. Their odour is resinous and agreeable, their taste bitter, balsamic, and somewhat acrid. Exposed to heat they melt and exhale a stronger odour. Tacamahac is partially soluble in alcohol, and completely so in ether and the fixed oils. It consists of resin with a little volatile oil.

Another variety is obtained from the E. Indies, and called *tacamahaca orientale*, or *tacamahaca in testis*. It is supposed to be derived from the *Calophyllum Inophyllum*, and comes into the market in gourd-shells covered with rush leaves. It is of a pale-yellow colour inclining to green, slightly translucent, soft and adhesive, of an agreeable odour, and an aromatic bitterish taste. It is at present very rare in commerce.

Guibourt describes several other varieties of tacamahac, which, however, are little known. Among them is a soft, adhesive, dark-green resin, said to be procured from the *Calophyllum Tacamahaca*, growing in the islands of Bourbon and Madagascar.

Tacamahac was formerly highly esteemed as an internal remedy, but is now employed medicinally only in the composition of ointments and plasters, and little even for this purpose. Its properties are analogous to those of the turpentines. It is sometimes used as incense.

TANNATE OF ALUMINA. *Aluminæ Tannas.* Mr. Rogers Harrison, of London, has employed an aqueous solution of a substance which he calls by this name, as an injection in gonorrhœa, after the acute symptoms have passed. He makes it of such a strength as always to produce smarting. The substance is described to be in crystals, about the size of those of coarse sugar, of a dirty-yellowish colour, and readily soluble in hot water. (*Lond. Med. Gaz.*, xiii. 853.) It is not easy to conjecture what is the substance employed

by Mr. Harrison. Tannate of alumina is nearly insoluble in water. Prof. Procter, of Philadelphia, tried to make a soluble tannate of this earth, but without success; and from the description of the substance used by Mr Harrison, he is inclined to the opinion that it was a mixture of tannic acid and alum. (See *Am. Journ. of Pharm.*, Jan. 1853, p. 25.)

TANNATE OF IRON. *Ferri Tannas.* This salt is prepared by dissolving 44 parts of precipitated subcarbonate of iron, moderately dried, in a boiling solution of 9 parts of pure tannic acid, evaporating the solution at the temperature of 176°, in a porcelain vessel, until it becomes thick, pouring it out on a glass or porcelain plate, and drying it with a gentle heat. As thus obtained, tannate of iron is in flat pieces, of a crimson colour, without taste, and insoluble in water. It acts as an astringent and tonic, and may be given in chlorosis, in the dose of from eight to thirty grains, in the course of a day, made into pills. *Ink* is an aqueous solution of the tanno-gallate of iron and probably possesses similar medical properties. It is a popular and efficacious application to ringworm.

TANNATE OF LEAD. *Plumbi Tannas.* This is obtained by precipitating a concentrated infusion of oak bark with acetate of lead, added drop by drop. It has been used as an external application with success by Dr. Fantonetti in two cases of white swelling of the knee-joint. He employed it at first mixed with a third of its weight of lard, and afterwards pure, the fresh precipitate admitting of application as an ointment. Autenrieth recommends it as a dressing to gangrenous sores. With this intention, the precipitate, either uncombined, or mixed in its dry state with simple ointment in the proportion of two drachms to the ounce, may be spread on linen, and applied to the sore. The preparation here referred to is a bitannate. Other tannates of lead exist.

TARTRATE OF SODA. *Sodæ Tartras.* This salt, in crystals, has been recommended by M. Delioux as an agreeable purgative, almost without taste, and acting with power equal to that of the sulphate of magnesia, in the dose of ten drachms. The *soda powders*, so much used in the United States, form an extemporaneous tartrate of soda, somewhat aërated with carbonic acid. (See *page* 1164.)

TEA. The plant which furnishes tea—*Thea Chinensis*—is an evergreen shrub, belonging to the class and order Monadelphia Polyandria of the sexual system (Polyandria Monogynia, *Linn.*), and to the natural order Ternstromiaceæ. It is usually from four to eight feet high, though capable, in a favourable situation, of attaining the height of thirty feet. It has numerous alternate branches, furnished with elliptical-oblong or lanceolate, pointed leaves, which are serrate, except at the base, smooth on both sides, green, shining, marked with one rib and many transverse veins, and supported alternately upon short footstalks. They are two or three inches long, and from half an inch to an inch in breadth. The flowers are either solitary, or supported two or three together at the axils of the leaves. They are of considerable size, not unlike those of the myrtle in appearance, consisting of a short green calyx with five or six lobes, of a corolla with from four to nine large unequal snow-white petals, of numerous stamens with yellow anthers and connected at their base, and of a pistil with a three-parted style. The fruit is a three-celled and three-seeded capsule. It has not been certainly determined whether more than one species of the tea plant exists. Linnæus admitted two species—*T. Bohea* and *T. viridis*—differing in the number of their petals: but this ground of distinction is untenable, as the petals are known to vary very much in the same plant. Hayne makes three species—*T. stricta*, *T. Bohea*, and *T. viridis*—which are distinguished severally by the shape of their leaves and fruit, and the direction of the footstalk. De Candolle admits but one species, with two varieties—the *viridis* or green tea, with "lanceolate flat leaves, three times as long as they are broad," and the *Bohea*, with "elliptical oblong, subrugose leaves, twice as long as broad." Lindley recognises the two Linnean species, distinguishing them by the leaves, which in *T. viridis* are acuminate and emarginate at the apex, and in *T. Bohea* are smaller, flatter, darker green, with small serratures, and terminate gradually in a point, but are not at all acuminate or emarginate. (*Flora Medica*, 120.)

The tea-plant is a native of China and Japan, and is cultivated in both countries, but most abundantly in the former. In Japan it forms hedgerows around the rice and corn-fields; in China, whence immense quantities of tea are exported, whole fields are devoted to its culture. It is propagated from the seeds, which are planted in holes at certain distances, six or eight seeds being placed in each hole, in order to ensure the growth of one. In three years the plant yields leaves for collection, and in six attains the height of a man. When from seven to ten years old it is cut down, in order that the numerous shoots which issue from the stump may afford a large product of leaves. These are picked separately by the hand. Three harvests, according to Kœmpfer, are usually made during the year; the first at the end of February, the second at the beginning of April, and the third in June. As the youngest leaves are the best, the product of the first collection is most valuable, while that of the third, consisting of the oldest leaves, is comparatively little

esteemed. Sometimes only one or two harvests are made; but care is always taken to assort the leaves according to their age; and thus originate numerous commercial varieties of tea. The character of the plant, dependent upon the soil, situation, climate, and culture, has also a great influence upon the value of the leaves. It is said that the best tea is procured from the shrubs which grow upon the sides of steep hills with a Southern exposure. Though the plant grows both about Pekin in the North and Canton in the South of China, it is said to attain greater perfection in the intermediate country, in the neighbourhood of Nankin, for instance, where the climate is neither so cold as in the first-mentioned vicinity, nor so hot as in the second. Some of the commercial varieties have their origin in this cause; and it is not improbable, though the fact has not been ascertained, that difference in species may be another source of diversity. After having been gathered, the leaves are dried by artificial heat in shallow iron pans, from which they are removed while still hot, and rolled with the fingers, or in the palm of the hand, so as to be brought into the form in which they are found in commerce. It is stated that the odour of the tea leaves themselves is very slight; and that it is customary to mix with them the leaves of certain aromatic plants, such as *Olea fragrans* and *Camellia Sasanqua*, in order to render them pleasant to the smell. The cultivation of tea has been successfully introduced into Brazil. (*Journ. de Pharm. et de Chim.*, xix. 276.)

Tea is brought to this country from Canton and other ports of China. Numerous varieties exist in commerce, differing in the shape communicated by rolling, in colour, in flavour, or in strength; but they may all be arranged in the two divisions of *green* and *black teas*, which, at least in their extremes, differ so much in properties, that it is difficult to conceive that they are derived from the same species.

Properties. Green tea is characterized by a dark-green colour, sometimes inclining more or less to blue or brown. It has a peculiar, refreshing, somewhat aromatic odour, and an astringent, slightly pungent, and agreeably bitterish taste. Its infusion has a pale greenish-yellow colour, with the odour and taste of the leaves. According to Mr. Warington, who examined numerous varieties of tea carefully both by the microscope and chemical tests, many of the green teas imported into Great Britain owe their colour to a powdery coating, consisting of sulphate of lime and Prussian blue, others to a mixture of these with a yellowish vegetable substance, and others, again, to sulphate of lime alone. (*Pharm. Journ. and Trans.*, iv. 37.) *Black tea* is distinguished by a dark-brown colour. It is usually less firmly rolled, and lighter than the green, and contains the petioles of the plant mingled with the leaves. Its odour is fainter, and of a somewhat different character, though still fragrant. Its taste, like that of green tea, is astringent and bitterish; but it is less pungent, and to many persons less agreeable. To hot water it imparts a brown colour, with its sensible properties of taste and smell. These vary exceedingly in strength in the different varieties; and some black teas are almost wholly destitute of aromatic or agreeable flavour. According to Mr. Warrington, the difference between green and black tea, so far as concerns their chemical and physical condition, arises from a species of fermentation which the latter is made to undergo, in its preparation, before being roasted. (*Pharm. Journ. and Trans.*, x. 618.) A sophisticated tea is largely exported from China, consisting of powdered tea mixed with sand and other earth, and agglutinated with gum; that which is to pass for black being coloured with plumbago, and the green with the coating above referred to. On analysis, these teas were found to afford from 35 to 45 per cent. of ashes, while the genuine yield only 5 per cent. They may be detected by not unfolding when steeped in boiling water. (*Ibid.*)

Analyzed by G. J. Mulder, 100 parts of green Chinese tea afforded 0·79 of volatile oil, 2·22 of chlorophylle, 0·28 of wax, 2·22 of resin, 8·56 of gum, 17·80 of tannic acid of the variety contained in galls, 0·43 of thein, 22·80 of extractive, traces of apotheme, 23·60 of muriatic extract, 3·00 of albumen, 17·68 of lignin, and 5·56 of salts. The muriatic extract was the matter taken up by diluted muriatic acid from tea, previously exhausted successively by ether, alcohol, and water, and consisted of artificial tannin. The same chemist obtained from 100 parts of black Chinese tea 0·60 of volatile oil, 1·84 of chlorophylle, 3·64 of resin, 7·28 of gum, 12·88 of tannic acid, 0·46 of thein, 19·88 of extractive, 1·48 of apotheme, 19·12 of muriatic extract, 2·80 of albumen, 28·32 of lignin, and 5·24 of salts. (*Annal. der Pharm.*, xxviii. 317.) Dr. Rochleder has found also a peculiar acid, which he calls *boheic acid*. M. Eug. Peligot obtained a much larger proportion of thein than was found by Mulder, the lowest quantity from green tea being 2·4 per cent. and the highest 4·1 per cent.; but even this quantity is too small to represent all the nitrogen contained in tea. (*Journ. de Pharm.*, *3e sér.*, iv. 224.) The volatile oil is probably one of the principles upon which the effects of tea upon the nervous system depend. Hence old teas are less energetic than those recently imported; and it is said that the fresh leaves have often produced dangerous effects in China. Nevertheless, the tannic acid is not without influence upon the system; and it is not improbable that both the extractive

and thein contribute to the peculiar influence of this valuable product. Of these active ingredients, the volatile oil, tannic acid, and extractive are found most largely, according to the analysis of Mulder, in the green tea. *Thein* is a crystallizable principle discovered by Oudry. It was afterwards proved by Jobst to have the same composition as caffein, and is now generally considered as in all respects identical with that principle. It is also said to exist in the leaves of the Ilex Paraguaiensis or Paraguay tea, and in the seeds of Paullinia sorbilis. (See *Coffee*, *Ilex*, and *Paullinia*.) According to Mulder, thein exists in tea combined with tannic acid. Peligot obtained it by adding to a hot infusion of tea, first subacetate of lead, and then ammonia, filtering the liquid, passing sulphuretted hydrogen through it, again filtering, and evaporating with a moderate heat. On cooling, the liquid deposits thein abundantly, and yields an additional quantity by a careful evaporation. (*Journ. de Pharm.*, 3e *sér.*, iv. 224.) It may be cheaply prepared by putting some old spoiled tea in an iron pot covered with filtering paper, enclosing the whole in a cylindrical paper cap, and cautiously applying heat. Thein rises in vapour and condenses on the paper. (See *Chem. Gaz.*, No. 178, p. 119.) Thein has a feebly bitter taste; in the state of crystals, is dissolved by 93 parts of water, 158 of alcohol, and 298 of ether; melts at about 350° F., and at 723° sublimes in white vapours which condense in minute needles. From its watery solution scarcely any reagent precipitates it. Infusion of galls causes a deposit of tannate of thein, which is again, however, dissolved by heating the water.

Medical Properties and Uses. Tea is astringent and gently excitant, and in its finer varieties exerts a decided influence over the nervous system, evinced by the feelings of comfort and even exhilaration which it produces, and the unnatural wakefulness to which it gives rise, when taken in unusual quantities, or by those unaccustomed to its use. Its properties, however, are not of so decided a character as to render it capable of very extensive application as a medicine; and its almost exclusive use is as a grateful beverage at the evening and morning meals. Taken moderately, and by healthy individuals, it may be considered as perfectly harmless; but long continued in excessive quantity, it is capable of inducing unpleasant nervous and dyspeptic symptoms, the necessary consequences of over-excitement of the brain and stomach. Green tea is decidedly more injurious in these respects than black, and should be avoided by dyspeptic individuals, and by those whose nervous systems are peculiarly excitable. As a medicine, tea may sometimes be given advantageously in diarrhœa; and a strong infusion will often be found to relieve nervous headache. The mode of preparing it for use is too well known to require description. An extract is made from it in China, which is said to be useful in fevers.

TELLURIUM. Several of the combinations of this metal have been tried on the living organism by M. Hansen. Five grains of the *tellurite of potassa*, given to dogs, produced stupefaction and vomiting, and the garlic-like odour of tellurium in the breath. The same salt, tried upon himself for seven successive days, in a dose daily of half a grain, afterwards increased to a grain, caused drowsiness at first, followed, after the seventh day, by a sense of oppression in the cardiac region, nausea, an increased flow of saliva, and loss of appetite. The breath had a garlic-like odour throughout the experiment. (*Chem. Gaz.*, March 1, 1854, p. 90.)

TEUCRIUM CHAMÆDRYS. *Germander. Chamædrys.* A small, didynamous, labiate, perennial European plant, the leaves and tops of which have an agreeable aromatic odour, diminished by drying, and a bitter, somewhat astringent, aromatic, durable taste. They have been employed as a mild corroborant, in uterine, rheumatic, gouty, and scrofulous affections, and intermittent fevers; but are at present little used, and never in this country. Germander was an ingredient in the *Portland powder*, noted as a remedy in gout. This powder, according to the original prescription, consisted of equal parts of the roots of *Aristolochia rotunda* and *Gentiana lutea*, of the tops and leaves of *Teucrium Chamædrys* and *Erythræa Centaurium*, and of the leaves of *Ajuga Chamæpytis*, or *ground pine*. The dose was a drachm taken every morning before breakfast, and continued for three months, then two scruples for three months, afterwards half a drachm for six months, and finally half a drachm every other day for a year. (*Parr.*)

Two other species of Teucrium have been used in medicine—*T. Marum*, *cat thyme*, or *Syrian herb mastich*, which is a native of the South of Europe, and *T. Scordium*, or *water germander*, growing in the higher latitudes of the same continent. The former is a warm, stimulating, aromatic bitter, and has been recommended in hysteria, amenorrhœa, and nervous debility; the latter has the odour of garlic, and a bitter, somewhat pungent taste, and was formerly highly esteemed as a corroborant in low forms of disease; but neither of them is now much employed. *T. Marum* is errhine, and was formerly an ingredient in the *Pulvis Asari Compositus*. The dose of either of the three species is about half a drachm. A plant said to have been used advantageously in cholera in the Levant, a specimen of which was sent to Paris, proved to be *Teucrium Polium*. (*Journ. de Pharm. et de Chim.*, xv. 352.)

THUJA OCCIDENTALIS. *Arbor Vitæ.* An indigenous evergreen tree, growing wild from Canada to Carolina, and cultivated for ornament in gardens. The leaves, or small twigs invested with the leaves, are the part used. They have an agreeable balsamic odour, especially when rubbed, and a strong, balsamic, camphorous, bitter taste. In the state of decoction, they have been used in intermittent fever, and, according to Schoepf, in coughs, fevers, scurvy, and rheumatism. Made into an ointment with lard or other animal fat, they are said to form a useful local application in rheumatic complaints. The distilled water is praised by Boerhaave as a remedy in dropsy. (*Schoepf.*) A yellowish-green volatile oil, which may be obtained from the leaves by distillation, has been used with success in worms.

THYMUS VULGARIS. *Thyme.* A small, well known undershrub, indigenous in the South of Europe, and with us cultivated in gardens. The herbaceous portion, which should be gathered when the plant is in flower, has a peculiar, strong, aromatic, agreeable odour, which is not lost by drying, and a pungent, aromatic, camphorous taste. Its active constituent is a volatile oil, which may be separated by distillation. Oil of thyme (*oleum thymi*) is, when fresh, of a pale-yellow or greenish colour, but as found in the shops is often brown. Its sp. gr. is 0·905. It is said to be commonly sold under the name of oil of origanum. The plant has the aromatic properties of sage, lavender, &c., and may be used for the same purposes. It is, however, more employed in cookery than in medicine. The *T. serpillum*, or *wild thyme* of Europe, is analogous in properties to the garden thyme. Both are occasionally used in baths, fomentations, and poultices, along with other aromatic herbs.

TONKA BEAN. The seed of *Dipterix odorata* of Willd., the *Coumarouna odorata* of Aublet, a large tree growing in Guiana. The fruit is an oblong-ovate pod, enclosing a single seed, from an inch to an inch and a half long, from two to four lines broad, usually somewhat compressed, with a dark-brown, wrinkled, shining, thin, and brittle skin, and a light-brown, oily kernel. The bean has a strong, agreeable, aromatic odour, and a bitterish, aromatic taste. Its active constituent is a crystallizable, odorous substance, analogous to the volatile oils and camphor, and called *coumarin* by Guibourt. This substance is sometimes found in a crystalline state, between the two lobes of the kernel. It has been shown by M. Bleibtreu to be identical with the odorous principle of *Asperula odorata*, *Trifolium melilotus*, and *Anthoxanthum odoratum*. (See *Chem. Gaz.*, Feb. 16, 1852, p. 61.) The tonka bean is used to flavour snuff, being either mixed with it in the state of powder, or put entire into the snuff-box.

TRIGONELLA FŒNUMGRÆCUM. *Fenugreek.* An annual plant growing spontaneously in different parts of the South of Europe, and cultivated in France and Germany for the sake of its seeds. These are one or two lines in length, oblong-cylindrical, somewhat compressed, obliquely truncated at each extremity, brownish-yellow externally, yellow internally, and marked with an oblique furrow running half their length. They have a strong peculiar odour, and an oily, bitterish, farinaceous taste, and contain fixed and volatile oil, mucilage, bitter extractive, and a yellow colouring substance. An ounce of the seeds boiled in a pint of water render it thick and slimy. They yield the whole of their odour and taste to alcohol. Their virtues depend chiefly upon their oil and mucilage. On the continent of Europe they are employed in the preparation of emollient cataplasms and enemata, and enter into the composition of some officinal ointments and plasters. They are never used internally.

TRILLIUM. This is an indigenous genus of pretty little herbaceous plants, growing generally in woods and shady places. The roots are reputed to possess valuable remedial properties. They were employed by the aborigines, have been long used in domestic practice in some parts of the country, and were noticed as medicinal in Henry's Herbal, published in 1812. Dr. S. W. Williams published a paper upon them in the *New England Journ. of Med. and Surg.*, in the year 1820, and has since published another in the *N. Y. Journ. of Med.* (viii. 94). The roots have a somewhat balsamic odour and taste, and produce, when chewed, a sense of heat and irritation, with an increased flow of saliva. They are thought to be astringent; and tonic, expectorant, and alterative properties have been ascribed to them. They have been used by the vulgar to hasten parturition. The complaints in which they are said to have been employed most successfully are the hemorrhages; but they have been used also in cutaneous affections, and externally in obstinate ulcers. Dr. Williams gives a drachm of the powdered root three times a day. Of the different species, the *T. erectum* is generally esteemed most active; though little is known of their relative value.

TRIPOLI. *Terra Tripolitana.* An earthy mineral, of a whitish, yellowish, or pale straw colour, sometimes inclining to red or brown, usually friable, often adhesive to the tongue, and presenting the aspect of argillaceous earth, though differing from clay by the rough-

ness and hardness of its particles, and by not forming a paste with water. The *Venice tripoli* is said to come from Corfu. Tripoli is sometimes artificially prepared by calcining certain argillites. It is used for cleaning and polishing metals.

TRITICUM REPENS. *Couch-grass. Dog-grass. Quickens.* A perennial European plant, very common in gardens, and cultivated grounds, where it is considered a troublesome weed. The root, which is the part medically used, is horizontal, creeping, jointed, about as thick as a straw or thicker, inodorous, and of an agreeable, sweetish, slightly pungent taste. It is used in some parts of Europe, in the form of decoction, as a slightly aperient and nutritive drink. Great quantities of it are said to be consumed in the hospitals of Paris. The decoction, in consequence of the sugar which it contains, is susceptible of the vinous fermentation.

TUSSILAGO FARFARA. *Coltsfoot.* Coltsfoot is a perennial herb, with a creeping root, which early in the spring sends up several leafless, erect, simple, unifloral scapes or flower-stems, five or six inches high, and bearing appressed scale-like bractes of a brownish-pink colour. The flower, which stands singly at the end of the scape, is large, yellow, compound, with hermaphrodite florets in the disk, and female florets in the ray. The latter are numerous, linear, and twice the length of the former. The leaves do not make their appearance until after the flowers have blown. They are radical, petiolate, large, cordate, angular, and toothed at the margin, bright-green upon their upper surface, white and downy beneath. The plant grows spontaneously both in Europe and North America. In this country it is found upon the banks of streams in the Middle and Northern States, and flowers in April. The whole of it is employed, but the leaves most so. They should be gathered after their full expansion, but before they have attained their greatest magnitude. The flowers have an agreeable odour, which they retain after desiccation. The dried root and leaves are inodorous, but have a rough, bitterish, mucilaginous taste. Boiling water extracts all their virtues. Coltsfoot exercises little sensible influence upon the human system. It is, however, demulcent, and is sometimes used in chronic coughs, consumption, and other affections of the lungs. The expectorant properties which it was formerly thought to possess are not obvious. The leaves were smoked by the ancients in pulmonary complaints; and in some parts of Germany they are at the present time said to be substituted for tobacco. Cullen states that he found the expressed juice of the fresh leaves, taken to the extent of some ounces every day, beneficial in several cases of scrofulous sores; and a decoction of the dried leaves, as recommended by Fuller, answered a similar purpose, though it often failed to effect a cure.

The usual form of administration is that of decoction. An ounce or two of the plant may be boiled in two pints of water to a pint, of which a teacupful may be given several times a day.

TUTTY. *Tutia. Impure Oxide of Zinc.* This oxide is formed during the smelting of lead ores containing zinc. It is deposited in the chimneys of the furnaces, in the form of incrustations, moderately hard and heavy, and studded over with small protuberances, of a brownish colour on the outside, and yellowish within. As it occurs in commerce, the pieces occasionally present a bluish cast, from the presence of small particles of metallic zinc. Sometimes a spurious substance is sold for tutty, consisting of a mixture of blue clay and copper filings, made into a paste with water, and dried on an iron rod. It is distinguished from the genuine tutty by its diffusing in water and exhaling an earthy smell, and by its greater friability.

Tutty is used as an external application only, being employed as a desiccant in excoriations. To fit it for medical use it must be reduced to fine powder, which is dusted on the affected part, or applied in the form of ointment. It has been very properly dismissed from the Edinburgh officinal list; its use being superseded by that of the pure oxide.

ULTRAMARINE. This fine blue pigment was formerly obtained from *lapis lazuli* or *lazulite*, a mineral of Siberia. It is now prepared artificially by mixing equal parts of sulphur, carbonate of soda, and silica, adding enough solution of soda to dissolve the silica, and rapidly igniting the mixture. A bluish-green mass results, which becomes blue by ignition in contact with air. It is thought to be a compound of the silicates of alumina and soda with sulphuret of sodium. (*Pharm. Journ. and Trans.*, xi. 230.)

UMBER. *Terra Umbria.* A mineral of a fine compact texture, light, dry to the touch, shining when rubbed by the nail, and of a fine pale-brown colour, which changes to a peculiar beautiful deep-brown by heat. According to Klaproth, it contains 13 parts of silica, 5 of alumina, 48 of oxide of iron, 20 of manganese, and 14 of water in 100. *Burnt umber*, as well as the mineral in its unaltered state, is used in painting. The umber of commerce is said to be brought chiefly from the island of Cyprus.

URATE OF AMMONIA. *Ammoniæ Uras.* ($NH_4O,N_4C_{10}H_2O_4+HO$.) This salt may be formed by digesting uric acid in solution of ammonia. Uric acid is generally obtained from

the dried and powdered excrement of the boa serpent, and of other large snakes, by dissolving it in a solution of potassa with the aid of heat, and precipitating the uric acid from the filtered solution by muriatic acid, added in excess. Urate of ammonia is a white, amorphous, very sparingly soluble salt. It is a constituent of some varieties of guano; and the medicinal properties of that substance are attributed by some to its presence. This salt has been used with good effects by Dr. Bauer, of Germany, as an external application, in the form of ointment, in chronic cutaneous eruptions, and in tubercular diseases of the lungs. The ointment is made of a scruple of the salt to an ounce of lard, and is applied to the eruptions night and morning, and, in the pectoral disease, by friction, night and morning, alternately to the back and front of the chest. (*Medico-Chirurg. Review*, July, 1852, p. 207, from *Buchner's Repert.*)

UREA. ($N_2C_2H_4O_2$.) This substance, the characteristic organic constituent of urine, is identical with the hydrated cyanate of ammonia (NH_3,NC_2O+HO), which salt is the first example of an organic product artificially formed. When obtained from urine, the most convenient process is that proposed by Dr. Gregory, which consists in saturating concentrated urine with oxalic acid, dissolving in water the oxalate of urea formed, decolorizing the solution with animal charcoal, digesting it with carbonate of lime, separating the precipitated oxalate of lime by filtration, and concentrating the filtrate that crystals may form. For the mode of obtaining artificial urea, the reader is referred to chemical treatises.

Urea is in the form of silvery acicular crystals, colourless and free from odour when pure, somewhat resembling nitre in appearance, and having a similar saline, cooling taste. It is soluble in its weight of cold water, and in every proportion in hot water. Though neither acid nor alkaline in its reaction, yet it is capable of uniting with several acids, forming crystallizable compounds like salt. This substance was proposed many years ago by the French physicians as a diuretic; and its use in this way has been revived by Dr. T. H. Tanner, of London. In the few cases in which Dr. Tanner tried the remedy, it acted as a powerful diuretic, without giving rise to any unpleasant symptom whatever. The dose to begin with is ten grains every six hours, dissolved in water, flavoured with syrup; the action of the medicine being aided by the free administration of diluents, and by keeping the skin moderately cool. (See *Braithwaite's Retrospect*, xxv. 161.)

URTICA DIOICA. *Common nettle.* A well known perennial herbaceous plant, growing both in Europe and the United States, by the roadsides, in hedges, and gardens. The leaves, seeds, and roots were formerly officinal. They were deemed diuretic and astringent, and were employed in nephritic complaints, hemorrhages, consumption, jaundice, worms, &c. The young shoots are boiled and eaten by the common people as a remedy in scurvy; and the fresh plant is sometimes used to excite external irritation in cases of torpor and local palsy, the part being beaten with it till the requisite degree of action is produced. The irritant effect of the nettle, applied to the skin, is said to be owing to the presence of free formic acid in the sharp hairs. (See *Am. Journ. of Pharm.*, xxii. 181.) The *U. urens* or *dwarf nettle*, which is an annual plant, and smaller than the former species, has similar properties, and is used for the same purposes. This species also grows wild both in America and Europe. The two plants were formerly distinguished by the names of *urtica major*, applied to *U. dioica*, and of *urtica minor* to *U. urens*. Dr. U. B. Johnson, of Marion, Alabama, has found the U. urens very efficacious in uterine hemorrhage. (*N. Orleans Med. and Surg. Journ.*, vi. 452.)

VALERIANATE OF BISMUTH. *Bismuthi Valerianas.* This salt is formed by double decomposition between solutions of nitrate of bismuth and valerianate of soda. Valerianate of bismuth precipitates as a white powder, which is washed with water, and dried by a gentle heat. It has been recommended by Righini in neuralgia and painful affections of the stomach. The dose is from half a grain to two grains, repeated several times a day, and given in the form of pill.

VANILLA. This has been supposed to be the fruit of *Vanilla aromatica* of Schwartz, the *Epidendrum Vanilla* of Linn., a climbing plant growing in the West Indies, Mexico, and South America. It is said also to be cultivated in the Isle of France and Bourbon. Doubts, however, exist whether the best commercial vanilla is derived from this species, and some ascribe it to the *Vanilla planifolia.* (*Journ. de Pharm. et de Chim.*, xvi. 274.) The pods are collected before they are quite ripe, dried in the shade, covered over with a coat of fixed oil, and then tied in bundles, which are surrounded with sheet lead, or inclosed in small metallic boxes, and sent into the market. Several varieties of vanilla exist in commerce. The most valuable, called *ley* by the Spaniards, consists of cylindrical, somewhat flattened pods, six or eight inches long, three or four lines thick, nearly straight, narrowing towards the extremities, bent at the base, shining and dark-brown externally, wrinkled longitudinally, soft and flexible, and containing within their tough shell, a soft black pulp, in which numerous minute, black, glossy seeds are embedded. It has a peculiar, strong,

agreeable odour, and a warm, aromatic, sweetish taste. The interior pulpy portion is most aromatic. Another variety, called *simarona* by the Spaniards, is smaller, of a lighter colour, and less aromatic. A third variety is the *promprona* of the Spaniards. In this, the pods are from five to seven inches long, from six to nine lines broad, almost always open, brown, soft, viscid, and of a strong odour, but less pleasant than that of the *ley*, to which it is considered inferior. According to Bucholz, vanilla does not yield volatile oil when distilled with water. It is employed to flavour chocolate, ice-cream, &c., and as a perfume. It has been recommended as a remedy in hysteria and low fevers, in the form of an infusion made in the proportion of about half an ounce to a pint of boiling water, and given in tablespoonful doses. Prof. Procter prepares a *fluid extract of vanilla* by the following process. An ounce of vanilla, cut transversely into short pieces, is rubbed with two ounces of granular sugar to coarse powder, and then submitted to percolation with deodorized alcohol, until a pint of tincture is obtained. This is evaporated with a gentle heat to one-half, twelve fluidounces of syrup are added, and the evaporation is continued until the liquid measures a pint, after which it is strained. Thus prepared it has the odour and taste of the vanilla in perfection.

VENETIAN RED. *Bolus Veneta.* A dull red ochrey substance used in painting.

VERBASCUM THAPSUS. *Mullein.* This is a biennial plant, with an erect, round, rigid, hairy stem, which rises from three to six feet in height, and is irregularly beset with large, sessile, oblong or oval, somewhat pointed leaves, indented at the margin, woolly on both sides, and decurrent at the base. The flowers are yellow, and disposed in a long, close, cylindrical, terminal spike.

The mullein is common throughout the United States, growing along the roadsides and in neglected fields, and springing up abundantly in newly cleared places, at the most remote distance from cultivation. It is, however, considered by many botanists as a naturalized plant, introduced originally from Europe, where it is also abundant. It flowers from June to August. The leaves and flowers have been employed. Both have a slight, somewhat narcotic smell, which in the dried flowers becomes agreeable. Their taste is mucilaginous, herbaceous, and bitterish, but very feeble. They impart their virtues to water by infusion. Mullein leaves are demulcent and emollient, and are thought to possess anodyne properties, which render them useful in pectoral complaints. On the Continent of Europe, an infusion of the flowers, strained in order to separate the rough hairs, is considerably used in mild catarrhs. Dr. Home found a decoction of the leaves useful in diarrhœa. The infusion or decoction may be prepared in the proportion of an ounce of the leaves to a pint of water, and given in the quantity of four fluidounces. The leaves are also employed externally, steeped in hot water, as a feebly anodyne emollient. An ointment is prepared from them in the recent state, and used for the same purposes. It may be made in the same manner as ointment of stramonium, by boiling the leaves in lard. It will be found advantageous to moisten them with water previously to the boiling.

VERBENA OFFICINALIS. *Vervain.* This is a common European weed, growing on the roadsides, in the vicinity of towns and villages. Its sensible properties do not indicate the possession of medical virtues; as it is nearly inodorous, and has only a slightly astringent bitterish taste. By the ancients it was highly esteemed both as a medicine, and as a sacred plant employed in certain religious rites. In modern times, superstitious notions in relation to its virtues are still entertained; and the suspension of the root around the neck by a white riband, has been gravely recommended for the cure of scrofula. The leaves, bruised and made into a cataplasm, are used by the vulgar as a remedy in severe headache, and other local pains. The plant, however, is probably inert. An American species, the *V. hastata*, is more bitter than the European, and is said to be emetic. It is not, however, used in regular practice. Schoepf states that the root of the *V. urticifolia*, another indigenous species, has been advantageously used in poisoning from the Rhus Toxicodendron. It is prepared by boiling it in milk and water along with the inner bark of the white oak.

VERDITER. Two preparations of copper, employed as pigments, are known by this name in commerce, and are distinguished by the epithets of blue and green. *Blue verditer* is prepared in London from the solution of nitrate of copper obtained in precipitating silver by copper. According to Gray, this solution is poured hot upon whiting (carbonate of lime), and the mixture stirred every day till the liquor loses its colour, when it is decanted, and fresh portions added till the proper colour is obtained. By a process for procuring this pigment, invented by Pelletier, the solution of nitrate of copper is decomposed by quicklime, and the precipitate, after being washed, is incorporated intimately with another portion of quicklime. By the former process, a carbonate of copper is obtained; by the latter, a mixture of the hydrated oxide of copper and hydrate of lime. *Green verditer* is prepared by precipitating a solution of nitrate of copper by chalk or a

white marl, and consists of carbonate of copper mixed with an excess of the calcareous carbonate.

VERONICA OFFICINALIS. *Speedwell.* Several species of Veronica, common to Europe and this country, have been medicinally employed. Of these the V. officinalis, and *V. Beccabunga* or *brooklime*, are the most conspicuous. *V. officinalis* has a bitterish, warm, and somewhat astringent taste; has been considered diaphoretic, diuretic, expectorant, tonic, &c.; and was formerly employed in pectoral and nephritic complaints, hemorrhages, and diseases of the skin, and in the treatment of wounds. The *beccabunga*, which is very succulent, was used in the fresh state with the view of purifying the blood, and as a remedy in scurvy. Both plants, however, are at present out of use.

VISCUM ALBUM. *Mistletoe.* A European evergreen parasitic shrub, growing on various trees, particularly the apple and other fruit trees, and forming a pendent bush from two to five feet in diameter. The plant is famous in the history of druidical superstition. In the religious rites of the Druids, the mistletoe of the oak was employed, and hence was afterwards preferred when the plant came to be used as a remedy; but it is in fact identical in all respects with those which grow upon other trees. The fresh bark and leaves have a peculiar disagreeable odour, and a nauseous, sweetish, slightly bitter taste. The berries, which are white, and of about the size of a pea, abound in a peculiar viscid principle, and are sometimes used in the preparation of bird-lime, of which this principle is the basis. At one time the mistletoe was highly esteemed as a remedy in epilepsy, palsy, and other nervous diseases; but it is now out of use. The leaves and wood were given in the dose of a drachm in substance, and of an ounce in decoction. Several species of Viscum grow in the United States, but are not used.

WHITING. This is essentially the same as prepared chalk, being made by the pulverization and elutriation of crude chalk. It is used as a coarse paint, and for various purposes in the arts, for which carbonate of lime is requisite. *Paris white* is a variety of the same material.

WOORARI. The name of a powerful poison, prepared by the aborigines in the interior of British Guiana, and used for arming the points of their weapons. Various opinions have been advanced in relation to its source and preparation; but the most probable account is that of Dr. Hancock, who states, from information derived from the natives, that it is a watery extract from the bark of a gourd-like plant. When this poison is inserted in a wound, the animal speedily falls into a state of stupor, and dies in a few minutes, the heart continuing to act for some time after respiration has ceased. If artificial respiration be resorted to before the heart has ceased to act, and be sustained, the animal recovers. Dr. Hancock states that it is swallowed by animals with impunity. It has not been introduced into medicine. For further notice in relation to it, the reader is referred to the *Lond. Pharm. Journ. and Trans.*, iii. 75.

WORMSEED, EUROPEAN. *Santonici Semen. Semen Cynæ. Semen Contra.* This product has been discarded from the Dublin Pharmacopœia of 1850. It was formerly ascribed in that work, in accordance with the general belief at one time, to *Artemisia Santonica* or *Tartarian Southernwood;* but upon insufficient grounds. European wormseed is of two kinds; one called the Aleppo, Alexandria, or Levant wormseed, the other Barbary wormseed. The former is supposed to be the product of *Artemisia Contra*, which grows in Persia, Asia Minor, and other parts of the East. It consists in fact not of the seeds, but of the small globular unexpanded flowers of the plant, mixed with their broken peduncles, and with minute, obtuse, smooth leaves. It has a greenish colour, a very strong aromatic odour increased by friction, and a very bitter disagreeable taste. The Barbary wormseed is thought by some to be derived from *Artemisia Judaica*, by others from the *A. glomerata* of Sieber, both of which grow in Palestine and Arabia. It consists of broken peduncles, having the calyx sometimes attached to their extremity. The calyx is also sometimes separate, consisting of very small linear obtuse leaflets. The flowers are wanting, or in the shape of minute globular buds. All these parts are covered with a whitish down, which serves to distinguish this variety from the wormseed of the Levant. It is, moreover, lighter and more coloured than the latter. Its smell and taste are the same.

These products contain a volatile oil and a resinous extractive matter, to which their virtues have been ascribed. A peculiar principle has also been discovered in them, which has received the name of *santonin.* It is crystallizable, colourless, tasteless, but leaving a slight sense of acrimony in the mouth, inodorous, soluble in ether and alcohol, and nearly insoluble in water. Its alcoholic solution has a decided bitterness. Though neuter in its action upon test-paper, it combines with the alkalies to form soluble and crystallizable salts. It may be obtained by treating wormseed with hydrate of lime and alcohol, evaporating the tincture to one-quarter, filtering the residue to separate the resin, and

treating it while hot with concentrated acetic acid. The santonin is deposited in crystals as the liquor cools. It is a powerful anthelmintic, and, from its want of taste, is much used in Europe in the treatment of worms in children. The dose is from one to four grains twice a day. It has also been employed with considerable asserted success in the treatment of intermittent fever. In over-doses it may prove dangerous. The case of a child of four years old is recorded, in which, after the administration of only three grains, severe abdominal pains came on with vomiting and purging, great prostration, cold sweats, spasms of the extremities, and dilated pupils; though the patient ultimately recovered. (*Ann. de Thérap.*, 1852, p. 218.) For details as to the mode of extracting santonin, the reader is referred to the *American Journal of Pharmacy* (vol. xv. p. 278). We have received a very handsome specimen of it from Messrs. Powers and Weightman, manufacturing chemists of Philadelphia.

The products above described have long been celebrated as a vermifuge, and the title of *semen contra*, by which they are designated in many works on pharmacy, originated in their anthelmintic property. They may be given in powder or infusion. The dose in substance is from ten to thirty grains, which should be repeated morning and evening for several days, and then followed by a brisk cathartic. They are not used in this country, having been superseded by the seeds of *Chenopodium anthelminticum*, which are universally known among us by the name of wormseed.

XANTHORRHŒA RESINS. Two resinous substances, the products of different species of Xanthorrhœa, have recently been introduced into England from New Holland. They are obtained by spontaneous exudation from the stems of the plants, which are usually shrubs. One of the resins is yellow and the other red. The *yellow variety* is in tears, in flattish pieces having on one side the mark of the stem, or in masses of various size and irregular shape. It has a reddish-yellow colour, resembling gamboge when broken, and when heated emits a fragrant odour like that of Tolu balsam. It contains resin, cinnamic and benzoic acids, and a trace of volatile oil, and may therefore be ranked among the balsams. When heated with nitric acid, it yields a large product of carbazotic acid. In medical properties it is said to bear a close resemblance to storax and the balsam of Tolu. A tincture, made in the proportion of two ounces to a pint of alcohol, may be given in the dose of one or two fluidrachms. The *red variety* resembles dragon's blood in colour, and appears to be analogous to the other variety in properties. The above account has been abridged from that of Dr. Pereira in the third edition of his Materia Medica.

ZEA MAYS. *Indian Corn. Maize.* Common Indian corn contains, according to the late Dr. Gorham, of Boston, 77 per cent. of starch, 3 of a principle analogous to gluten, called *zein*, 2·5 of albumen, 1·45 of sugar, 0·8 of extractive, 1·75 of gum, 1·5 of sulphate and phosphate of lime, 3 of lignin, and 9 of water. The meal, in the form of mush, makes an excellent emollient poultice, much used in hospitals; and a gruel may be prepared from it, which is sometimes more grateful to the sick than that made from oat meal.

ZEDOARY. *Radix Zedoariæ.* There are two kinds of zedoary, the long and the round, distinguished by the old officinal titles of *radix zedoariæ longæ*, and *radix zedoariæ rotundæ*; the former produced by the *Curcuma Zedoaria* of Roxburgh, the latter, as some suppose, by the *Kæmpferia rotunda* of Linn., but, according to others, by the *Curcuma Zerumbet* of Roxburgh. Both kinds come from the East Indies. The *long zedoary* is in slices, from an inch and a half to three inches in length, and from half an inch to an inch thick, obtuse at the extremities, and exhibiting the remains of the radical fibres; the *round* is also usually in slices, which are the sections of a roundish root, ending in a point beneath, and divided longitudinally into two parts, each of which is flat on one side, convex on the other, and heart-shaped in its outline. Sometimes the root of the latter variety is entire, and sometimes in quarters instead of halves. It is marked with circular rings on the convex surface, and, like the former, with small projecting points which are the remains of radical fibres. Both are grayish-white on the outside, yellowish-brown within, hard, compact, of an agreeable aromatic odour, and a bitterish, pungent, camphorous taste. The round, however, is less spicy than the long. They yield a volatile oil when distilled with water.

Zedoary is a warm, stimulating aromatic, useful in flatulent colic and debilitated states of the digestive organs. It is not now employed, as it produces no effects which cannot be as well or better obtained from ginger. The dose is from ten grains to half a drachm.

ZERUMBET. *Cassumuniar.* Under these names an East India root was formerly used, having some analogy in sensible and medical properties to ginger, and ascribed to the *Zingiber Zerumbet* of Roscoe. Some consider the cassumuniar as a distinct root, and refer it to the *Zingiber Cassumuniar* of Roxburgh. The difference of opinion is of little importance, as neither of the roots, supposing them not to be the same, is at present to be found in the markets. By some authors the zerumbet has been erroneously confounded with

the round zedoary. Geiger describes it as in pieces of the size of a fig or larger, externally grayish-brown and wrinkled, internally yellowish, hard and tough, of a biting aromatic taste, and a spicy odour.

ZIZYPHUS VULGARIS. Lamarck. *Rhamnus Zizyphus.* Linn. A shrub, or small tree, growing on the shores of the Mediterranean, and cultivated in Italy, Spain, and the South of France. The fruit is the part used. This consists of oval drupes, of the size of a large olive, with a thin, coriaceous, red or reddish-brown skin, a yellowish, sweet, acidulous pulp, and an oblong pointed stone in the centre. These have the officinal name of *jujubæ*. By drying, their pulp becomes softer and sweeter, and acquires a vinous taste, evincing the commencement of fermentation. They are nutritive and demulcent, and are used in the form of decoction in pectoral complaints. *Jujube paste* consists, properly, of gum Arabic and sugar, dissolved in a decoction of this fruit, and evaporated to the proper consistence. As a demulcent, it is in no respect superior to a paste made with gum Arabic and sugar alone; and the preparation commonly sold in this country under the name, contains in fact none of the fruit.

The fruits of two other species of Zizyphus, the *Z. Lotus*, growing in the North of Africa, and the *Z. Jujuba*, a native of the East Indies, possess properties similar to those of the first-mentioned species, and are used as food by the inhabitants of the countries where they grow.

Note.—Of the articles included in the foregoing list, those upon *Acetate of Copper, Acetate of Magnesia, Acetic Ether, Albuminate of Iron and Potassa, Ammonio-tartrate of Iron, Anthrakokali, Arseniate of Ammonia, Arseniate of Iron, Benzoate of Ammonia, Benzole, Bisulphuret of Carbon, Bromide of Iron, Bromides of Mercury, Carburet of Iron, Cheltenham Salt, Chloride of Magnesium, Chloride of Mercury and Quinia, Chloride of Potassa, Chloride of Silver, Chlorinated Anæsthetic Compounds, Chromic Acid, Citrate of Iron and Magnesia, Citrate of Iron and Quinia, Citrate of Soda, Crabs' Claws, Crabstones, Crocus of Antimony, Cyanuret of Zinc, Diaphoretic Antimony, Dippel's Animal Oil, Ferrocyanuret of Zinc, Artificial Fruit Essences, Fuligokali, Glass of Antimony, Gold, Guano, Gun Cotton, Hydriodic Acid, Hydriodic Ether, Hydrocyanic Ether, Hyposulphite of Soda, Hyposulphite of Soda and Silver, Indelible Ink, Indian Yellow, Iodide of Ammonium, Iodide of Barium, Iodide of Silver, Iodide of Starch, Iodide of Zinc, Iodides of Calomel, Iodoform, Iodohydrargyrate of Potassium, Lactate of Iron, Lactic Acid, Lithia, Manganese, Meat Biscuit, Muriatic Ether, Artificial Musk, Naphthaline, Nitrate of Copper, Nitrate of Soda, Nitroprusside of Sodium, Nitrosulphate of Ammonia, Nitrous Oxide, Oxalic Acid, Phosphate of Ammonia, Phosphate of Potassa, Platinum, Powder of Algaroth, Pyroacetic Spirit, Soot, Succinic Acid, Sulphate of Alumina, Sulphate of Alumina and Iron, Sulphate of Cadmium, Sulphate of Nickel, Sulphite of Soda, Sulphocyanuret of Potassium, Sulphuret of Calcium, Tannate of Alumina, Tannate of Iron, Tannate of Lead, Tartrate of Soda, Tellurium, Tutty, Urate of Ammonia, Urea, and Valerianate of Bismuth,* were written by Dr. Bache; the remainder by Dr. Wood.

II. ART OF PRESCRIBING MEDICINES.

The physician should be acquainted not only with the properties of medicines, and the diseases to which they are respectively applicable, but also with the art of prescribing them, so that they may be adapted to the peculiarities of individual patients, and, by the mode in which they are administered, may produce the greatest curative effect with the least possible inconvenience. In relation to these points, a few general rules will be useful for the guidance of the young practitioner, although much must be left to his own judgment and discretion. We shall compress the remarks which we have to offer, under the two heads of the quantity or dose in which medicines may be given, and the mode of their exhibition.

1. Dose of Medicines.—In the body of the work, the quantity has been stated in which each medicine must ordinarily be given to produce its peculiar effects in the adult patient. But there are various circumstances which modify the dose, and demand attention on the part of the practitioner.

The *age* of the patient is the most important of these circumstances. The young require a smaller dose than those of maturity, to produce an equal effect; and the old, though their systems are, perhaps, less susceptible to the action of medicines than those of the middle-aged, cannot bear an equally forcible impression. The following table of Gaubius, exhibiting the doses proportioned to the age, is frequently referred to.

The dose for a person of middle age being	1 or 1 drachm,
That of a person from 14 to 21 years will be	$\frac{2}{3}$ or 2 scruples,
7 to 14 " "	$\frac{1}{2}$ or $\frac{1}{2}$ a drachm,
4 to 7 " "	$\frac{1}{3}$ or 1 scruple,
of 4 years "	$\frac{1}{4}$ or 15 grains,
3 " "	$\frac{1}{6}$ or 10 grains,
2 " "	$\frac{1}{8}$ or 8 grains,
1 year "	$\frac{1}{12}$ or 5 grains.

We prefer the following simple scheme of Dr. Young, which we extract from Paris's Pharmacologia.

"For children under twelve years, the doses of most medicines must be diminished in the proportion of the age to the age increased by 12; thus at two years to $\frac{1}{7}$—viz., $\frac{2}{2+12}=\frac{1}{7}$. At twenty-one the full dose may be given."

To the above rule some exceptions are offered in particular medicines, which require to be given to children in much larger proportional doses than those above stated. Such are castor oil and calomel, a certain quantity of which will in general not produce a greater effect in a child two or three years old than double the quantity in an adult.

Sex, *temperament*, and *idiosyncrasy* have also an influence upon the dose, and should be kept in view in prescribing. Females usually require somewhat smaller doses than males, and persons of sanguine temperament than the phlegmatic. Constitutional peculiarities, called idiosyncrasies, often exist in individuals, rendering them more than usually susceptible or insusceptible to the action of certain remedies, the dose of which must be modified accordingly. Thus in some per-

sons a grain or two of calomel will excite salivation, while in others scarcely any quantity which can be safely administered will produce this effect. Sometimes, moreover, a medicine operates on an individual in a manner wholly different from its ordinary mode. In all such cases experience is the only sure guide; but the occasional existence of these peculiarities indicates the propriety of making particular inquiries in relation to the idiosyncrasies of those patients, for whom we may be called for the first time to prescribe.

Habit is another important circumstance which modifies the dose of medicines. Generally speaking, the susceptibility to the action of medicines is diminished by their frequent and continued use; and, in order to maintain a given impression, the quantity must be regularly increased. This is especially true in regard to the narcotics, which are sometimes borne in enormous doses by those habituated to their use. It is a good practical rule in prescribing, when circumstances demand the continuance, for a considerable length of time, of some particular effect, to vary the medicine, and employ successively several with the same general powers, so as not too rapidly to exhaust the susceptibility to the action of any individual remedy. Another important practical rule connected with the influence of habit is, when any medicine, which from its nature is of variable strength, has been employed for some time in increasing doses, to reduce the dose upon resorting to a new parcel, until its relative strength has been ascertained. A neglect of this precaution, in cases where the last parcel happened to be more powerful than that previously employed, has sometimes been followed by very serious consequences.

2. Mode of Administering Medicines.—This has reference both to the combination of medicines with one another, and the form in which they are exhibited.

Simplicity in prescription is always desirable, when no object is to be gained by deviating from it. Remedies should never be mixed together without a definite purpose, nor with the vague hope that, out of the number prescribed, some one may perchance produce a salutary impression. Those exceedingly complex prescriptions, formerly so much in vogue, of which the ingredients were so numerous as to render altogether impossible a reasonable estimate of their bearing on each other, or their effects on disease, have been generally abandoned by modern practitioners. The only ground upon which any of them can be justifiably retained is that, by very frequent trials, through a long course of years, and in various states of disease, their influence on the system may have been fully ascertained, so that they may be considered rather in the light of a single remedy than a compound of many. Upon this ground, however, no prudent physician would attempt to originate such combinations. In mixing medicines, we ought to proceed no further than we should be justified in doing by a clear knowledge of the properties and mutual relations of the several ingredients, and their fitness to answer some particular indication in the treatment of disease. There are certain principles upon which medicines may be advantageously combined, and which it may not be amiss to mention for the benefit of the young practitioner.

Remedies of the same general character may be given in connexion, in order to increase their energy, or to render their action more certain. It has been well ascertained that substances thus combined will often act vigorously, when, severally, they would produce comparatively little effect; and it sometimes happens that, while their activity is augmented, they are at the same time rendered less irritating, as in the case of the drastic cathartics. (See *Pilulæ Cathartice Compositæ.*)

Different medicines are very often mixed together, in order to meet different and co-existing indications, without any reference to the influence which they

may reciprocally exert on each other. Thus in the same patient we not unfrequently meet with debility of stomach and constipation of the bowels, connected with derangement of the hepatic function. To answer the indications presented by these morbid conditions, we may properly combine in the same dose, a tonic, cathartic, and mercurial alterative. For similar reasons we often unite tonics, purgatives, and emmenagogues, anodynes and diaphoretics, emetics and cathartics, antacids, astringents, and tonics; and scarcely two medicines can be mentioned, not absolutely incompatible with each other, which may not occasionally be combined with advantage to counteract co-existing morbid conditions.

Another very important object of combination, is the modification which is thereby effected in the actions of medicines differing from each other in properties. In this way new powers are sometimes developed, and those previously existing are greatly increased. Examples of such a result are afforded in the officinal powder of ipecacuanha and opium, and in the combination of squill and calomel; the former operating as a diaphoretic, the latter as a diuretic beyond the capabilities of either of their constituents. The effects of one medicine are, in numerous instances, increased by the influence of another in augmenting the natural susceptibility of the system to its action. Thus bitters enable cathartics to operate in smaller doses; purgatives awaken the dormant susceptibility to the action of mercury; and stimulants excite the torpid stomach, so that it will receive impressions from various medicines before inoperative. In some instances, the action of one medicine is promoted by that of another apparently of a nature wholly opposite. Thus, when calomel and opium are given in colic, the purgative operation of the former is facilitated by the relaxation of intestinal spasm produced by the latter. Medicines, in addition to the effects for which they are administered, very frequently produce disagreeable symptoms, which may be moderated or altogether prevented by combination with other medicines; and this object may usually be accomplished, without in the least degree interfering with the remediate influence desired. Thus the griping produced by cathartics, and the nausea by these and various other medicines, may often be corrected by the simultaneous use of aromatics. To cover the disagreeable taste or odour of certain medicines, and to afford a convenient vehicle for their administration, are also important objects of combination; as upon these circumstances often depend the acceptability of the medicine to the stomach, and even the possibility of inducing the patient to swallow it. Substances should be preferred as vehicles which are calculated to render the medicine acceptable to the palate and stomach, and in other ways to correct its disagreeable effects; as syrups for powders, the aromatic waters for medicines given in the form of mixture, and carbonic acid water for the neutral salts.

But, in the mixing of medicines, care should be taken that they are neither chemically nor physiologically incompatible; in other words, that they are not such as will react on each other so as to produce new and unexpected combinations, nor such as will exert contrary and opposite effects upon the system. Thus when the operation of an acid is desired, an alkali should not be given at the same time, as they unite to form a third substance entirely different from either; nor should a soluble salt of lime, baryta, or lead be given with sulphuric acid or a soluble sulphate, as decomposition would ensue, with the production of an inert compound. So, also, in relation to physiological incompatibility, diaphoretics and diuretics should not, as a general rule, be united with a view to their respective effects; as these are to a certain extent incompatible, one being diminished by whatever has a tendency to increase the other. There are cases, however, in which we may advantageously combine medicines with a view to their chemical reaction, as in the instance of the effervescing draught; and circumstances sometimes call for the union of remedies apparently opposite, as

in the case of colic before alluded to, in which opium may be advantageously combined with purgatives. Still, such combinations should never be formed, unless with a full understanding of their effects, and a special reference to them.

The *form in which medicines are exhibited*, is often an object of considerable importance. By variation in this respect, according to the nature of the medicine, the taste of the patient, or the condition of the stomach, we are frequently enabled to secure the favourable operation of remedies, which, without such attention, might prove useless or injurious. Medicines may be given in the solid state, as in the form of powder, pill, troche, or electuary; in the state of mixture, in which a solid is suspended in a liquid, or one liquid is mechanically mixed with another in which it is insoluble; or in the state of solution, under which may be included the various forms of infusion, decoction, tincture, wine, vinegar, syrup, honey, and oxymel. Of these different forms we have already treated sufficiently at large, under their respective heads, in the second part of this work.

In writing extemporaneous prescriptions, neatness, order, and precision, should always be observed; as, independently of the pleasing moral effect inseparable from these principles in all things, a positive practical advantage results, in the greater accuracy which the habit of attending to them gives to the prescriber, and the comparative certainty which they afford that his directions will be strictly complied with. As a general rule, when medicines are combined in prescription, that should come first in order which is considered as the most prominent and important, next the adjuvant or corrigent, and lastly the vehicle. Sometimes, however, it is important to indicate to the apothecary the succession in which the substances should be combined in reference to the perfection of the mixture, and this may render convenient a deviation from the order above mentioned. The physician should always be careful either to write out the full name of the medicine, or to employ such abbreviations as are not likely, by the misunderstanding of an ill-formed letter, to lead into error. Very serious and even fatal mistakes have been occasioned by a neglect of this precaution. The formulæ of the several Pharmacopœias which are detailed in this work, will serve as good examples for the guidance of the young practitioner. The following table explains the signs and abbreviations habitually used in prescriptions. The formulæ afterwards given will serve to illustrate the ordinary mode of prescribing, while they exhibit combinations of medicines frequently employed in practice.

W.

Table of Signs and Abbreviations.

℞	Recipe.	Take.	Collyr.	Collyrium.	An eye-water.
āā	Ana.	Of each.	Cong.	Congius vel Congii.	A gallon or gallons.
℔	Libra vel libræ.	A pound or pounds.	Decoct.	Decoctum.	A decoction.
℥	Uncia vel unciæ.	An ounce or ounces.	Ft.	Fiat.	Make.
ʒ	Drachma vel drachmæ.	A drachm or drachms.	Garg.	Gargarysma.	A gargle.
℈	Scrupulus vel scrupuli.	A scruple or scruples.	Gr.	Granum vel grana.	A grain or grains.
♎	Octarius vel octarii.	A pint or pints.	Gtt.	Gutta vel guttæ.	A drop or drops.
fʒ	Fluiduncia vel fluidunciæ.	A fluidounce or fluidounces.	Haust.	Haustus.	A draught.
fʒ	Fluidrachma vel fluidrachmæ.	A fluidrachm or fluidrachms.	Infus.	Infusum.	An infusion.
♏	Minimum vel minima.	A minim or minims.	M.	Misce.	Mix.
Chart.	Chartula vel chartulæ.	A small paper or papers.	Mass.	Massa.	A mass.
Coch.	Cochlear vel cochlearia.	A spoonful or spoonfuls.	Mist.	Mistura.	A mixture.
			Pil.	Pilula vel pilulæ.	A pill or pills.
			Pulv.	Pulvis vel pulveres.	A powder or powders.
			Q. S.	Quantum sufficit.	A sufficient quantity.
			S.	Signa.	Write.
			Ss.	Semis.	A half.

Examples of Common Extemporaneous Prescriptions.

POWDERS.

℞ Antimonii et Potassæ Tartratis gr.i.
Pulveris Ipecacuanhæ ℈i.
Fiat pulvis.
S. To be taken in a wineglassful of sweetened water.
An active emetic.

℞ Hydrargyri Chloridi Mitis,
Pulveris Jalapæ, āā gr.x.
Misce.
S. To be taken in syrup or molasses.
An excellent cathartic in the commencement of bilious fevers, and in hepatic congestion.

℞ Pulveris Jalapæ gr.x.
Potassæ Bitartratis ʒii.
Misce.
S. To be taken in syrup or molasses.
A hydragogue cathartic, used in dropsy, and in scrofulous inflammation of the joints.

℞ Sulphuris ʒi.
Potassæ Bitartratis ʒii.
Misce.
S. To be taken in syrup or molasses.
A laxative used in piles and cutaneous diseases.

℞ Pulveris Rhei gr.x.
Magnesiæ ʒss.
Fiat pulvis.
S. To be taken in syrup or molasses.
A laxative and antacid, used in diarrhœa, dyspepsia, &c.

℞ Pulveris Scillæ gr.xii.
Potassæ Nitratis ʒi.
Fiat pulvis, in chartulas sex dividendus.
S. One to be taken twice or three times a day in syrup or molasses.
A diuretic employed in dropsy.

℞ Potassæ Nitratis ʒi.
Antimonii et Potassæ Tartratis gr.i.
Hydrarg. Chlorid. Mitis gr.vi.
Fiat pulvis, in chartulas sex dividendus.
S. One to be taken every two hours in syrup or molasses.
A refrigerant, diaphoretic, and alterative, used in bilious fevers; usually called *nitrous powders.*

℞ Pulveris Guaiaci Resinæ,
Potassæ Nitratis, āā ʒi.
Pulveris Ipecacuanhæ gr.iii.
Opii gr.ii.
Fiat pulvis, in chartulas sex dividendus.
S. One to be taken every three hours in syrup or molasses.
A stimulant diaphoretic, used in rheumatism and gout after sufficient depletion.

℞ Ferri Subcarbonatis,
Pulveris Colombæ,
Pulveris Zingiberis, āā ʒi.
Fiat pulvis, in chartulas sex dividendus.

S. One to be taken three times a day in syrup or molasses.

A tonic, used in dyspepsia and general debility.

Pills.

℞ Pulveris Aloës,
Pulveris Rhei, āā ʒss.
Saponis ℈i.
Misce, et cum aquâ fiat massa in pilulas viginti dividenda.

S. Two or three to be taken daily, at bed-time, or before a meal.

An excellent laxative in habitual constipation.

℞ Massæ Pilularum Hydrargyri,
Pulveris Aloës,
Pulveris Rhei, āā ℈i.
Misce, et cum aquâ fiat massa in pilulas viginti dividenda.

S. Three to be taken at bed-time.

An alterative and laxative, useful in constipation with deranged or deficient hepatic secretion.

℞ Pulveris Aloës,
Extracti Quassiæ, āā ʒi.
Olei Anisi ♏x.
Syrupi q. s.
Misce, et fiat massa in pilulas triginta dividenda.

S. Two to be taken once, twice, or three times a day.

A laxative, tonic, and carminative, useful in dyspepsia.

℞ Pulveris Scillæ ℈i.
Hydrargyri Chloridi Mitis gr.x.
Pulveris Acaciæ,
Syrupi, āā q. s.
Misce, et fiat massa in pilulas decem dividenda.

S. One to be taken two or three times a day.

A diuretic and alterative, much used in dropsy, especially when complicated with organic visceral disease.

℞ Pulveris Opii gr.iv.
Pulveris Ipecacuanhæ gr.xviii.
Pulveris Acaciæ,
Syrupi, āā q. s.
Misce, et fiat massa in pilulas duodecim dividenda.

S. One to be taken after each stool.

An anodyne diaphoretic, useful in dysentery and diarrhœa after the use of laxatives.

℞ Pulveris Opii,
Pulveris Ipecacuanhæ, āā gr.iii.
Hydrargyri Chloridi Mitis gr.vi.
Pulveris Acaciæ,
Syrupi, āā q. s.
Misce, et fiat massa in pilulas tres dividenda.

S. One or more to be taken at bed-time, or according to circumstances.

An anodyne, diaphoretic, and alterative, very useful in diarrhœa, dysentery, typhoid pneumonia, and various other diseases.

℞ Plumbi Acetatis, in pulv. triti, gr.xii.
Pulveris Opii gr.i.
Pulv. Acaciæ,
Syrupi, āā q. s. ut fiat massa in pilulas sex dividenda.

S. One every two, three, or four hours.

An astringent much employed in hæmoptysis and uterine hemorrhage.

Mixtures.

℞ Magnesiæ ʒi.
Syrupi fʒi.
Tere simul, et affunde
Aquæ Acidi Carbonici fʒiv.
Fiat haustus.

S. To be taken at a draught, the mixture being well shaken.

An agreeable mode of administering magnesia.

℞ Mannæ ʒi.
Fœniculi contusi ʒi.
Aquæ bullientis fʒiv.
Fiat infusum et cola; dein adjice
Magnesiæ Carbonatis ʒii.
Ft. mist.

S. One-third to be taken every three or four hours till it operates, the mixture being shaken.

An excellent carminative and mild laxative in flatulence and pain in the bowels.

℞ Olei Ricini fʒi.
Pulveris Acaciæ,
Sacchari, āā ʒii.
Aquæ Menthæ Piperitæ fʒiii.
Acaciam et saccharum cum fluiduncîâ dimidiâ aquæ menthæ tere; dein oleum adjice, et contere; denique aquam reliquam paulatim infunde, et omnia misce.

S. To be taken at a draught, the mixture being well shaken.

℞ Olei Ricini f℥i.
Vitellum ovi unius.
Tere simul, et adde
Syrupi f℥ss.
Aquæ Menthæ Piperitæ f℥ii.
Ft. haust.

S. To be taken at a draught, the mixture being well shaken.

This and the preceding formula afford convenient modes of administering castor oil, when the stomach is irritable. Any other fixed oil may be given in the same way. Half the quantity will often answer.

℞ Olei Ricini f℥iss.
Tincturæ Opii ♏xxx.
Pulv. Acaciæ,
Sacchari, āā ℥ii.
Aquæ Menthæ Viridis f℥iv.

Acaciam et saccharum cum paululo aquæ menthæ tere; dein oleum adjice, et iterum tere; denique aquam reliquam paulatim infunde, et omnia misce.

S. A tablespoonful to be taken every hour or two hours till it operates, the mixture being each time well shaken.

Used as a gentle laxative in dysentery and diarrhœa. It is usually known by the name of *oleaginous mixture.*

℞ Elaterii gr.i.
Spiritûs Ætheris Nitrici f℥ii.
Tincturæ Scillæ,
Vini Colchici Rad., āā f℥ss.
Syrupi f℥i.
Ft. mist.

S. A tablespoonful to be taken three or four times a day in a little water.

Diuretic, used by Ferriar in dropsy.

℞ Copaibæ,
Spiritûs Lavandulæ Comp., āā f℥ii.
Mucilaginis Acaciæ f℥ss.
Syrupi f℥iii.
Simul tere; dein paulatim affunde
Aquæ f℥iv.
Misce.

S. A tablespoonful to be taken four times a day, or more frequently.

Given in chronic catarrh, and chronic nephritic affections. The dose must be larger in gonorrhœa.

Neutral Mixture.

℞ Acidi Citrici ℥ii.
Olei Limonis ♏i.
Simul tere, et adde
Aquæ f℥iv.
Liqua, et adde
Potassæ Carbonatis q. s. ad saturand.
Misce, et per linteum cola.

Or,

℞ Succi Limonis recentis f℥iv.
Potassæ Carbonatis q. s. ad saturandum.
Misce et cola.

S. A tablespoonful to be given with an equal quantity of water, every hour or two hours.

An excellent diaphoretic in fever.

Effervescing Draught.

℞ Potassæ Carbonatis ℥ii.
Aquæ f℥iv.
Liqua.

Or,

℞ Potassæ Bicarbonatis ℥iii.
Aquæ f℥iv.
Liqua.

S. Add a tablespoonful of the solution to the same quantity of lemon or lime-juice, previously mixed with a tablespoonful of water; and give the mixture, in the state of effervescence, every hour or two hours.

An excellent diaphoretic and anti-emetic in fever with nausea or vomiting.

Brown Mixture.

℞ Pulv. Extract. Glycyrrhizæ,
Pulv. Acaciæ, āā ℥ii.
Aquæ ferventis f℥iv.
Liqua, et adde
Vini Antimonii f℥ii.
Tincturæ Opii ♏xx.
Ft. mist.

S. A tablespoonful to be taken occasionally.

Expectorant, demulcent, and anodyne, useful in catarrhal affections.

℞ Antimonii et Potassæ Tartratis gr.i.
Syrupi Scillæ,
Liquoris Morphiæ Sulphatis, āā f℥ss.
Pulveris Acaciæ ℥ii.
Syrupi f℥ss.
Aquæ f℥iv.
Ft. mist.

S. A tablespoonful to be taken occasionally.

An expectorant and anodyne cough mixture.

℞ Acidi Nitrosi f℥i.
Tincturæ Opii gtt.xl.
Aquæ Camphoræ f℥viii.
Misce.

S. One-fourth to be taken every three or four hours.

Hope's mixture, used in dysentery, diarrhœa, and cholera.

℞ Camphoræ ℥i.
Myrrhæ ℥ss.
Pulv. Acaciæ,
Sacchari, āā ℥ii.
Aquæ f℥vi.

Camphoram cum alcoholis paululo in pulverem tere; dein cum myrrhâ, acaciâ, et saccharo contere; denique cum aquâ paulatim instillatâ misce.

S. A tablespoonful to be taken for a dose, the mixture being well shaken.

A convenient form for administering camphor.

℞ Cretæ Præparatæ ℈iv.
Massæ Pil. Hydrarg. gr.viii.
Tincturæ Opii gtt.viii.
Pulveris Acaciæ,
Sacchari, āā ʒi.
Aquæ Cinnamomi,
Aquæ, āā fʒi.
Solida simul tere, dein liquida paulatim inter terendum adjice, et omnia misce.

S. A teaspoonful to be taken for a dose, the mixture being well shaken.

An antacid and alterative mixture, well adapted to infantile diarrhœa with white stools. The dose mentioned is for a child a year or two old, and may be repeated four or six times in twenty-four hours.

℞ Pulveris Kino ʒii.
Aquæ bullientis fʒvi.
Fiat infusum et cola; dein secundum artem admisce,
Cretæ Præparatæ ʒiii.
Tincturæ Opii fʒss.
Spiritûs Lavandulæ Compositi fʒss.
Pulveris Acaciæ,
Sacchari, āā ʒii.

S. A tablespoonful to be taken for a dose, the mixture being well shaken.

Astringent and antacid, useful in diarrhœa.

Solutions.

℞ Magnesiæ Sulphatis ʒi.
Syrupi Limonis fʒi.
Aquæ Acidi Carbonici fʒvi.
Misce.

S. To be taken at a draught.

An agreeable mode of administering sulphate of magnesia.

℞ Magnesiæ Sulphatis ʒi.
Antimonii et Potassæ Tartratis gr.i.
Succi Limonis recentis fʒi.
Aquæ fʒiii.
Misce.

S. A tablespoonful to be taken every two hours till it operates upon the bowels.

Useful in fevers.

℞ Potassæ Nitratis ʒi.
Antimonii et Potassæ Tartratis gr.i.
Aquæ fʒiv.
Liqua.

S. A tablespoonful to be taken every two hours.

A refrigerant diaphoretic, used in fevers.

℞ Quiniæ Sulphatis gr.xii.
Acidi Sulphurici Aromatici gtt.xxiv.
Syrupi fʒss.
Aquæ Menthæ Piperitæ fʒi.
Misce.

S. A teaspoonful to be taken every hour or two hours.

A good mode of administering sulphate of quinia in solution.

Infusions.

℞ Sennæ ʒiii.
Magnesiæ Sulphatis,
Mannæ, āā ʒss.
Fœniculi ʒi.
Aquæ bullientis Oss.
Macera per horam in vase leviter clauso, et cola.

S. A teacupful to be taken every four or five hours till it operates.

An excellent purgative in febrile complaints.

℞ Spigeliæ ʒss.
Sennæ ʒii.
Mannæ ʒi.
Fœniculi ʒii.
Aquæ bullientis Oi.
Macera per horam in vase leviter clauso, et cola.

S. A wineglassful to be given to a child from two to four years old, three or four times a day.

A powerful anthelmintic.

℞ Colombæ contusæ,
Zingiberis contusi, āā ʒss.
Sennæ ʒii.
Aquæ bullientis Oi.
Macera per horam in vase leviter clauso, et cola.

S. A wineglassful to be taken morning, noon, and evening, or less frequently if it operate too much.

An excellent remedy in dyspepsia with constipation and flatulence.

℞ Pulveris Cinchonæ Rubræ ʒi.
Acidi Sulphurici Aromatici fʒi.
Aquæ Oi.
Macera per horas duodecim, subinde agitans.

S. A wineglassful of the clear liquid to be taken for a dose.

A good method of administering Peruvian bark in cold infusion.

III. TABLES OF WEIGHTS AND MEASURES.

APOTHECARIES' WEIGHT. *U. S., Lond., Ed.*

Pound.		Ounces.		Drachms.		Scruples.		Grains.
℔ 1	=	12	=	96	=	288	=	5760
		℥ 1	=	8	=	24	=	480
				ʒ 1	=	3	=	60
						℈ 1	=	gr. 20

The Imperial Standard Troy weight, at present recognised by the British laws, corresponds with the Apothecaries' weight in pounds, ounces, and grains, but differs from it in the division of the ounce, which, according to the former scale, contains twenty pennyweights, each weighing twenty-four grains.

AVOIRDUPOIS WEIGHT.

Pound.		Ounces.		Drachms.		Troy Grains.

		1	=	20	=	160	=	9600
				1	=	8	=	480
						1	=	60

* By this term is meant the division of weights adopted by the Dublin College in their Pharmacopœia of 1850. The division of the drachm and scruple is not the nearest approximation to accuracy. The precise number for the drachm is 54·6875, which would give as the nearest to the precise number, with two decimals, for the drachm 54·69, and for the scruple 18·23.

Relative Value of Apothecaries' and Imperial Measure.

In converting the weights of liquids heavier or lighter than water into measures, or conversely, a correction must be made for specific gravity. In converting weights into measures, the calculator may proceed as if the liquid was water, and the obtained measure will be to the true measure *inversely* as the specific gravity. In the converse operation, of turning measures into weights, the same assumption may be made, and the obtained weight will be to the true weight *directly* as the specific gravity.

FRENCH DECIMAL WEIGHTS AND MEASURES.

The French *metrical* system is based upon the idea of employing, as the unity of all measures, whether of length, capacity, or weight, a uniform unchangeable standard, adopted from nature, the multiples and subdivisions of which should follow in decimal progression. To obtain such a standard, the length of one-fourth part of the terrestrial meridian, extending from the equator to the pole, was ascertained. The ten millionth part of this arc was chosen as the unity of measures of length, and was denominated *metre*. The cube of the tenth part of the metre was taken as the unity of measures of capacity, and denominated *litre*. The weight of distilled water, at its greatest density, which this cube is capable of containing, was called *kilogramme*, of which the thousandth part was adopted as the unity of weight, under the name of *gramme*. The multiples of these measures, proceeding in the decimal progression, are

distinguished by employing the prefixes, *deca*, *hecto*, *kilo*, and *myria*, taken from the Greek numerals; and the subdivisions, following the same order, by *deci*, *centi*, *mili*, from the Latin numerals.

The *metre*, or unity of length, at 32°	= 39·371	English inches at 62°.
The *litre*, or unity of capacity	= 61·028	English cubic inches.
The *gramme*, or unity of weight	= 15·434	Troy grains.

Upon this basis the following tables, taken with some slight alterations from the Edinburgh New Dispensatory, have been constructed. It was ascertained by accurate examination at the London Mint, that the gramme is only 15·434 Troy grains, though sometimes stated at 15·444 grains.

MEASURES OF LENGTH.

The metre being at 32°, and the foot at 62°.

Myriagramme	=	154340·2344 =	26	9	4	20

Though the decimal system of weights and measures was established by law in France, it was found impossible to procure its general adoption by the people, who obstinately adhered to the old *poids de marc* and its divisions; or, if they adopted the new weights, gave them the names of the old weights to which they most nearly approached. Thus the *kilogramme*, which is equal to 18,827 $\frac{15}{100}$ French grains, or 2 pounds 5 gros 35 $\frac{15}{100}$ grains *poids de marc*, was divided into two parts, and the half of it called a pound. One reason for this adherence

to the old weights was the convenience of division into halves, quarters, &c., of which the new were not susceptible. To obviate this difficulty the Imperial government legalized the employment of the half kilogramme as the unity of weight, under the name of pound, and allowed this to be divided into half pounds, quarters, eighths, ounces, &c., as in the old *poids de marc*. The new pound is distinguished by the name of *metrical pound*, and has been adopted to a considerable extent; while the old weights are retained by some, particularly by the apothecaries and goldsmiths; so that three systems are now more or less in use in France—the original *poids de marc*, the decimal system, and the metrical pound with its divisions. The following table represents the relative value of these different weights.

Decimal System.		Poids de Marc.					Metrical Pound.				
		℔	oz.	dr.	gr.		℔	oz.	dr.	gr.
1 centigramme	=	0	0	0	0·19	=	0	0	0	0·18
1 decigramme	=	0	0	0	1·88	=	0	0	0	1·84
1 gramme	=	0	0	0	18·83	=	0	0	0	18·43

1 hectogramme	=	0	3	2	10·71	=	0	3	1	43·2
1 kilogramme	=	2	0	5	35·15	=	2	0	0	0

Poids de Marc.		Grammes.	Metrical Pound.		Grammes.
1 grain	=	0·0531	1 grain	=	0·054
24 grains or ℈i	=	1·2747	24 grains or ℈i	=	1·302
72 grains or ʒi	=	3·8242	72 grains or ʒi	=	3·906
1 ounce	=	30·5941	1 ounce	=	31·25
1 pound	=	489·5058	1 pound	=	500

The following table is taken from Christison's Dispensatory, and was calculated chiefly from data contained in Soubeiran's Traité de Pharmacie.

Table of certain foreign Apothecaries' Weights, exhibiting the Value of their different Denominations in Troy Grains.

	Pound.	Ounce.	Drachm.	Scruple.	Grain.
French (old) - -	5670·5	472·50	59·10	19·70	0·820
Spanish - - -	5320·4	443·49	55·44	18·47	0·769
Tuscan - - -	5240·3	436·67	54·58	18·19	0·758
Roman - - -	5235·0	436·25	54·53	18·17	0·757
Austrian - -	6495·1	541·25	67·65	22·55	1·127
German or Nuremberg or Russian - -	5524·8	460·40	57·55	19·18	0·960
Prussian - -	5415·1	451·26	56·40	18·80	0·940
Dutch or Belgian - -	5695·8	474·64	59·33	19·78	0·988
Swedish - -	5500·2	458·34	57·29	19·09	0·954
Piedmontese - -	4744·7	395·39	49·45	16·48	0·824
Venetian - -	4661·4	388·45	48·55	16·18	0·809

Of these weights, all, except the French, Spanish, Tuscan, and Roman (first named in the table), are divided into parts corresponding with those of the English Apothecaries' weight. In these four, the drachm contains 72 instead of 60 grains, and the scruple 24 instead of 20 grains; but, as in the English, there are 3 scruples in the drachm, 8 drachms in the ounce, and 12 ounces in the pound.

APPROXIMATE MEASUREMENT.

For the sake of convenience, in the absence of proper instruments, we often make use of means of measurement, which, though not precise nor uniform, afford results sufficiently accurate for ordinary purposes. Of this kind are certain household implements, of a capacity approaching to uniformity, and corresponding to a certain extent with the regular standard measures. Custom has attached a fixed value to these implements, with which it is proper that the practitioner should be familiar; although their capacity, as they are now made, with the exception of the wineglass, generally somewhat exceeds that at which they were originally and still continue to be estimated.

A *tea-cup* is estimated to contain about four fluidounces, or a gill.
A *wineglass* - - - - two fluidounces.
A *tablespoon* (cochlear magnum) - half a fluidounce.
A *teaspoon* (cochlear parvum) - a fluidrachm.

Small quantities of liquid medicines are often estimated by *drops*, each of which is usually considered equivalent to a minim, or the sixtieth part of a fluidrachm. The drop of water and of watery fluids is, on an average, about this size; but the same is by no means the case with all medicinal liquids, and the drop even of the same liquid varies much in bulk, according to the circumstances under which it is formed. This is, therefore, an uncertain mode of estimating the quantity of liquids, and should be superseded where minim measures can be had.

The results stated in the following table were obtained by Mr. E. Durand, of Philadelphia. (See *Journ. of the Philadelphia College of Pharmacy*, i. 169.) They may be relied on as accurate, but should be considered as indicating only the relative number of drops afforded by the several liquids mentioned; for, under other circumstances than those of Mr. Durand's experiments, entirely different results might be obtained as relates to each liquid. The preparations experimented with were those of the first edition of the U. S. Pharmacopœia.

Table, exhibiting the Number of Drops of different Liquids equivalent to a Fluidrachm.

	Drops.		Drops.
Acid, acetic (crystallizable)	120	Tincture of assafetida, of foxglove, of guaiac, of opium	120
Acid, hydrocyanic (medicinal)	45	Tincture of chloride of iron	132
Acid, muriatic	54	Vinegar, distilled	78
Acid, nitric	84	Vinegar of colchicum	78
Acid, nitric, diluted (1 to 7)	51	Vinegar of opium (black drop)	78
Acid, sulphuric	90	Vinegar of squill	78
Acid, sulphuric, aromatic	120	Water, distilled	45
Acid, sulphuric, diluted (1 to 7)	51	Water of ammonia (strong)	54
Alcohol (rectified spirit)	138	Water of ammonia (weak)	45
Alcohol, diluted (proof spirit)	120	Wine (Teneriffe)	78
Arsenite of potassa, solution of	57	Wine, antimonial	72
Ether, sulphuric	150	Wine of colchicum	75
Oil of aniseed, of cinnamon, of cloves, of peppermint, of sweet almonds, of olives	120*	Wine of opium	78

* See *page* 1098 for the results obtained by Professor Procter with the volatile oils, which give a considerably smaller number of drops to the fluidrachm than here stated, showing how different may be the results obtained under different circumstances.

quadrihydrated (sp. gr. 1·42)	NO_5+4HO	90

* This table includes all the elements, although many of them are not used in medicine. It also embraces a few compounds which are not used in pharmacy, but which are inserted on account of their general importance. Including aridium and donarium, the present number of the elements is 65.

† By modern chemists the elements are designated by letters, called *symbols*. The initial letter of the name is the symbol, whenever it is distinctive; but, when several elements have names beginning with the same letter, the plan adopted is to represent one of them by the initial letter, and the rest by the initial letter with some other associated with it. Thus C stands for carbon, Ca for calcium, Cd for cadmium, Ce for cerium, Cl for chlorine, Co for cobalt, Cr for chromium, Cu for copper, &c. The use of these symbols saves time and space in designating the composition of compounds. Where a single equivalent is intended to be designated, the symbol of the element is simply given; but where several equivalents are to be represented, the symbol is preceded by a figure indicating the number. Thus C means one equivalent of carbon, 2C two equivalents, and so on. Sometimes the number of equivalents is denoted by a small depressed figure following the symbol; and this plan has been adopted, in most instances, in the above table. The group of letters and figures, thus used to denote the composition of any compound, is called the *formula* of such compound. The symbols given are those of Berzelius, and should not be varied from, for fear of destroying their usefulness by creating confusion.

Glucina	G_2O_3	37·92
GLUCINIUM	G	6·96
Glycerin	$C_6H_7O_5+HO$	92
Glyceryle	C_6H_7	43

* According to M. H. Rose the columbium of Hatchett, and the tantalum of Ekeberg are distinct metals.

† This is the name given by M. Bergemann to a metal assumed to be present in an oxide, supposed to be new, found by him in a Norwegian mineral, called orangite. The oxide in question is now stated to be impure thorina; and, should this statement be confirmed, donarium must be struck from the list of metals.

crystallized	NiO,SO_3+7HO	140·5
NIOBIUM*	Nb	?

* Niobium and pelopium were alleged to exist in the Bavarian and North American columbites. Recently, however, M. H. Rose has announced that they are the same, and proposes to retain the name niobium. It is not contended that the peculiar metal of the columbites is different from that discovered in 1801 by Hatchett; and, therefore, as justly remarked by Prof. A. Connell, of St. Andrews, it should be called columbium, the name given to it by its discoverer, and the name niobium should be abandoned. (*Philos. Mag.*, June, 1854, p. 461.)

B.

V. CORRESPONDENCE BETWEEN DIFFERENT THERMOMETERS.

In *Fahrenheit's* thermometer, which is universally employed in this country and Great Britain, the freezing point of water is placed at 32°, and the boiling point at 212°, and the number of intervening degrees is 180.

The *Centigrade* thermometer, which has long been used in Sweden under the name of Celsius's thermometer, and is now most generally employed on the continent of Europe, marks the freezing point *zero*, and the boiling point 100°.

In *Reaumur's* thermometer, used in France before the revolution, the freezing point is at zero, and the boiling point at 80°.

In *De Lisle's* thermometer used in Russia, the graduation begins at the boiling point, which is marked *zero*, while the freezing point is placed at 150°.

From the above statement, it is evident that 180 degrees of Fahrenheit are equal to 100° of the centigrade, 80° of Reaumur, and 150° of De Lisle; or 1 degree of the first is equal to $\frac{5}{9}$ of a degree of the second, $\frac{4}{9}$ of a degree of the third, and $\frac{5}{6}$ of a degree of the last. It is easy, therefore, to convert the degrees of one into the equivalent number of degrees of the other; but, in ascertaining the corresponding points upon the different scales, it is necessary to take into consideration their different modes of graduation. Thus, as the zero of Fahrenheit is 32° below the point at which that of the centigrade and of Reaumur is placed, this number must be taken into account in the calculation. The following propositions will embrace all the cases which can arise in relation to the three last-mentioned thermometers. That of De Lisle is seldom or never referred to in works which are read in this country.

1. If any degree on the *centigrade* scale, either above or below zero, be multiplied by 9 and divided by 5, or if any degree of *Reaumur* above or below zero be multiplied by 9 and divided by 4, the quotient will, in either case, be the number of degrees above or below 32°, or the freezing point of *Fahrenheit.*

2. The number of degrees between any point of *Fahrenheit's* scale and 32°, if multiplied by 5 and divided by 9, will give the corresponding point on the *centigrade;* if multiplied by 4 and divided by 9, will give the corresponding point on the scale of *Reaumur.*

3. Any degree of the *centigrade* multiplied by 4 and divided by 5, will give the corresponding degree of *Reaumur;* and conversely, any degree of *Reaumur* multiplied by 5 and divided by 4, will give the corresponding degree of the *centigrade.*

VI. TABLES,

SHOWING THE SPECIFIC GRAVITY CORRESPONDING WITH THE SEVERAL DEGREES OF HYDROMETERS IN USE.

Baumé's hydrometer is usually employed in France. In this instrument, the sp. gr. of distilled water is assumed as the zero of the descending scale, in relation to fluids heavier than itself, while it is assumed as 10 on the ascending scale, in relation to lighter fluids. In the Pharmacopœia Batava, a modification of the instrument has been adopted, in which the sp. gr. of distilled water has been assumed as the zero of both scales. In the following tables, the specific gravity of liquids is given, corresponding with the several degrees of these two hydrometers. The first column of specific gravities, corresponding with Baumé's scale, is taken from the Paris Codex, and is, therefore, of high authority; the second is that which has been given in previous editions of this work, taken from Duncan's Edinburgh Dispensatory (A. D. 1830), and based on the calculations of Huss.

For Liquids lighter than Water.

The French Codex employs Baumé's hydrometer to indicate the density of iquids heavier than water; but for those lighter than water, it has recourse to the instrument of *Cartier*, as the one most diffused in commerce. This differs from Baumé's only in a slight modification of the scale. In both, the lowest point is 10°; but 30° of Cartier correspond with 32° of Baumé, so that 20 degrees of the former are equivalent to 22 of the latter. Such, at least, was the original relation of the two instruments; but that of Cartier has subsequently undergone some slight modifications. The following table, extracted from the Codex, shows the value of the several degrees of Baumé's scale in those of Cartier's. The *centesimal alcoholmeter* of Gay-Lussac is applicable only to alcohol. The scale of this instrument is divided into 100 unequal degrees, the zero corresponding to pure water, and 100° to absolute alcohol; and every intermediate degree expresses the per centage of pure alcohol, by measure, contained in the liquors examined. Thus, when the instrument stands at 40° in any alcoholic liquid, it indicates that 100 parts of the liquid contain 40 of pure alcohol and 60 of water. But, as it was graduated for the temperature of 59° of Fahrenheit, the liquors to be tested should be brought to that temperature. In *page* 62 of this Dispensatory is a table indicating the specific gravity corresponding with each per centage of alcohol by weight; and as, in the table given in the next page, the value of Cartier's degrees in those of the alcoholmeter is stated, there can be no difficulty in converting the degrees of any one of these instruments into those of another, or of ascertaining the specific gravity, or the per centage of alcohol whether by measure or weight, to which they respectively correspond.

THE END.

To all Physicians and Medical Students.

NEW AND VALUABLE MEDICAL BOOKS,

PUBLISHED BY

LIPPINCOTT, GRAMBO, & CO.,

PHILADELPHIA,

AND FOR SALE BY BOOKSELLERS GENERALLY IN THE UNITED STATES.

THE

DISPENSATORY OF THE UNITED STATES:

TENTH EDITION, IMPROVED.

CONSISTING OF

1st. A TREATISE ON MATERIA MEDICA, or the Natural, Commercial, Chemical, and Medical History of the Substances employed in Medicine, and recognized by the Pharmacopœias of the United States and Great Britain;

2d. A TREATISE ON PHARMACY: comprising an account of the preparations directed by the American and British Pharmacopœias, and designed especially to illustrate the Pharmacopœia of the United States; and

3d. A copious APPENDIX, embracing an account of all substances not contained in the officinal catalogues, which are used in medicine or have any interest for the Physician or Apothecary.

BY GEORGE B. WOOD, M. D.,

Professor of the Theory and Practice of Medicine in the University of Pennsylvania, &c. &c.

AND

FRANKLIN BACHE, M. D.,

Professor of Chemistry in the Jefferson Medical College of Philadelphia, &c. &c.

The work has been thoroughly revised, with many alterations and additions, so as to bring it fully up to the level of the present state of Materia Medica and Pharmacy. It embraces the substance of the recently revised United States and British Pharmacopœias, with a commentary on all that is new in those publications. Nothing, indeed, has been omitted in the revision, which could tend to render the work worthy of a continuance of the public confidence which it has so long enjoyed.

DR. WOOD'S PRACTICE.

A TREATISE

ON THE

PRACTICE OF MEDICINE.

IN TWO VOLS. OCTAVO. FOURTH EDITION, IMPROVED.

BY GEORGE B. WOOD, M. D.,

Professor of the Theory and Practice of Medicine in the University of Pennsylvania.

"This is by far the best work on the Practice of Medicine in the English language, and we recommend it strongly to the attention of our readers. It is much fuller than Dr. Watson's admirable Lectures, while it is less lengthy than the Library or Cyclopædia of Medicine; and it has this further advantage over the two last-named works—that while they are far behind, it is a fair reflex of the actual state of knowledge."—*London Medical Times and Gazette*, 1852.

A BEAUTIFUL ILLUSTRATED AMERICAN SURGERY.

SMITH'S OPERATIVE SURGERY;

Illustrated by nearly One Thousand Engravings on Steel,

MANY OF WHICH HAVE BEEN DAGUERREOTYPED FROM NATURE, AND FINISHED IN THE FINEST STYLE OF STEEL ENGRAVINGS.

The whole forming two large octavo volumes.

A SYSTEM OF OPERATIVE SURGERY;

BASED UPON THE PRACTICE OF

SURGEONS IN THE UNITED STATES:

AND COMPRISING

A full Bibliographical Index of the most important American Surgical Works and Papers,

AS WELL AS A

HISTORY OF AMERICAN SURGERY,

DURING A PERIOD OF TWO HUNDRED AND THIRTY-FOUR YEARS.

BY HENRY H. SMITH, M.D.,

Consulting Surgeon and Lecturer on Clinical Surgery in the Philadelphia Hospital;
Surgeon to the St Joseph's Hospital;
Lecturer on the Practice of Surgery in the Pennsylvania Academy of Medicine;
Fellow of the College of Physicians, Philadelphia, &c.

SECOND EDITION,

WITH NUMEROUS ADDITIONS IN BOTH THE TEXT AND ILLUSTRATIONS.

The Plates are presented either tinted or colored to life—and the work is in neat substantial binding.

Price, tinted, $7 50—colored to life, $15.

PUBLISHERS' NOTICE.

In tendering to the profession an original work on American Surgery, the publishers have spared no expense, and they now present it as a specimen of an Illustrated Surgery which is adapted to the wants of the practitioner and student. The laborious research evident in its pages is such as must recommend it to every practitioner who desires to be accurately informed of the acts of his countrymen, as well as of the most distinguished European surgeons, whilst the conciseness of the descriptions of the operative proceedings makes it valuable as a *text-book* for the student.

As each operation is preceded by an account of the surgical anatomy of the region, the practitioner who has been long absent from the dissecting-rooms will be able from the text, in connection with the plates, to refresh his anatomical knowledge and obtain almost as accurate an idea of the surgical relations of the part as if he had a recent dissection. The spirit and accuracy of the illustrations have gained for them the universal approbation of the medical journals, as expressed on the publication of the different parts. A few of the notices of the volume, as recently expressed, are hereafter quoted.

NOTICES OF THE PRESS.

"We are sure the profession will welcome this *truly national work* in preference to being dependent upon reprints of foreign books."—*New York Med. Gazette.*

"The beauty and extent of the illustrations would amply suffice to command attention; but its character as an essentially *American work*, built, as its title-page imports, upon a strictly national foundation, must secure for it a general welcome. *No book has hitherto been written* which has presented the American practitioner with a comprehensive view of the opinions, operative methods, and instruments of those who have given to American surgery a character of its own. The Bibliography is a treasure in itself, and a monument of the compiler's industry which must win for him the gratitude and esteem of every medical inquirer who can appreciate the vast amount of labor which its preparation has required."—*Philadelphia Medical Examiner.*

"Dr. Smith's work, the most *splendid* on Operative Surgery, is now before us. We cannot give a full outline of this very elaborate and complete work, but we take pleasure in saying that it is better adapted to the wants of the American practitioner than any which has preceded it in this or any other country. We have no hesitation in recommending it in the very highest terms to those who desire to perfect themselves in this department of our profession."—*Ohio Medical and Surgical Journal*, Jan. 1853.

"We have seen nothing like it, and the whole ground has been so thoroughly occupied by the persevering author, that it will be a long time before the work can have a rival. No one competent to estimate the value of these researches would hesitate an instant in admitting that it is a valuable and splendid book, and one which no surgeon can do without if he has a particle of ambition to keep pace with the progress of Operative Surgery on this continent."—*Boston Med. and Surg. Journal*, Nov. 1852.

THE UNITED STATES DISSECTOR;

OR,

LESSONS IN PRACTICAL ANATOMY.

BY WM. E. HORNER, M. D.

Fifth edition, 1 vol. 12mo.

CAREFULLY REVISED, AND ENTIRELY REMODELLED,

BY HENRY H. SMITH, M. D.

With one hundred and seventy-seven new illustrations.

ELEMENTS OF HUMAN ANATOMY.

BY T. G. RICHARDSON, M. D.,

OF LOUISVILLE, KENTUCKY.

WITH OVER FOUR HUNDRED ILLUSTRATIONS.

In one volume, octavo.

KOLLIKER'S ANATOMY OF THE HUMAN BODY.

A MANUAL OF

MICROSCOPICAL ANATOMY OF THE HUMAN BODY.

BY ALBERT KOLLIKER,

Professor of Anatomy and Physiology, in Wurtemberg.

TRANSLATED FROM THE GERMAN

BY J. DA COSTA, M. D.,

Member of the Academy of Natural Sciences, Philadelphia.

WITH THREE HUNDRED AND FIFTEEN WOOD-CUTS.

IN ONE VOLUME OCTAVO.

UNITED STATES PHARMACOPŒIA.

THE PHARMACOPŒIA OF THE UNITED STATES OF AMERICA.

BY AUTHORITY OF THE

NATIONAL MEDICAL CONVENTION,

HELD AT WASHINGTON, A. D. 1850.

IN ONE VOLUME OCTAVO.

GENERAL NOTIONS OF CHEMISTRY,

BEING A POPULAR AND GENERAL TREATISE.

BY J. PELOUZE,

Member of the Institute, &c.

AND

E. FREURY,

Professor of Chemistry in the Polytechnic School, &c.

TRANSLATED FROM THE FRENCH,

BY EDMUND C. EVANS, M. D.

One volume, octavo.

PLATES

OF THE

MUSCLES OF THE HUMAN BODY.

BY M. J. WEBER, M. D.,

Professor of Anatomy in the University of Bonn, Prussia.

ENGRAVED ON COPPER, WITH THE NAME ATTACHED TO EACH MUSCLE,

AFTER B. S. ALBINUS.

Price $2 50.

The Plates of the Muscles of the Human Body, as arranged by Prof. Weber, having obtained an extended circulation among the medical profession in Europe, are now presented to the students and practitioners of the United States, as calculated to facilitate the study of an extensive department of anatomy.

To those who have experienced the difficulties attendant on the use of such anatomical drawings as are accompanied by a separate explanatory text, and in which every point and corner of the illustration is covered by figures and lines of reference, the simplicity of the plan pursued by Prof. Weber will be readily apparent; the attachment of the name to the muscle to which it belongs rendering its origin, insertion, shape, and surgical relations evident at a glance.

These plates, therefore, present the student with information similar to that afforded by the map of a country, whilst they also enable the practitioner to recall, at a glance, the information which long absence from the dissecting-room often obliterates. Being adapted to every work on Special Anatomy, they are admirably suited to the instruction furnished in every medical school.

Should the utility of these plates be as generally approved as is anticipated, it is the intention of the author to furnish others of a similar character, illustrative of the OSSEOUS, VASCULAR, and NERVOUS SYSTEMS.

A SYSTEMATIC TREATISE,

HISTORICAL, ETIOLOGICAL, AND PRACTICAL,

ON THE

PRINCIPAL DISEASES

OF THE INTERIOR VALLEY OF NORTH AMERICA,

AS THEY APPEAR IN THE

CAUCASIAN, AFRICAN, INDIAN, AND ESQUIMAUX VARIETIES OF ITS POPULATION.

BY DANIEL DRAKE, M. D.

ONE VOLUME, LARGE OCTAVO.

WARRINGTON'S OBSTETRIC CATECHISM.

THE OBSTETRIC CATECHISM,

CONTAINING

TWO THOUSAND THREE HUNDRED AND FORTY-SEVEN QUESTIONS AND ANSWERS,

ON OBSTETRICS PROPER.

BY JOSEPH WARRINGTON, M. D.

One Hundred and Fifty Illustrations.

One Volume, 12mo., New Edition, Revised and Enlarged.

NEW AND POPULAR WORK ON

DOMESTIC MEDICINE AND SURGERY.

THE DICTIONARY

OF

DOMESTIC MEDICINE AND HOUSEHOLD SURGERY.

BY SPENCER THOMPSON, M. D., L. R. C. S., Edinburgh.

EDITED AND ADAPTED TO THE WANTS OF AN AMERICAN COMMUNITY, BY A WELL-KNOWN PRACTITIONER OF PHILADELPHIA.

ILLUSTRATED WITH NUMEROUS CUTS.

This work is intended to afford a concise and ready book of reference for families in cases of emergency, *during the absence of immediate medical assistance.* It will also serve as a safe guide in the domestic management of slight ailments and injuries, whilst affording instruction in the duties of the sick-room generally.

The touch of a gentle hand will not be less gentle, nor the safe domestic remedies be less carefully administered, when the attendant upon the sick is guided by a correct knowledge of the anatomical arrangement and physiological requirements of the human frame.

In many of the accidents of daily life, and especially in thinly populated districts, in the railroad car, and in the steamboat, the information possessed by a neighbor or bystander of "*what is best to be done,*" is often of essential service, and the Medical Dictionary of Domestic Surgery will always present under the appropriate heading precisely such information as is required.

As a compendium of those sanitary principles on which the preservation or attainment of health depends, it is recommended to the intelligent mechanic, inexperienced mother or emigrant; whilst, as a counter-agent to the impudent quackery which preys upon the ignorance and credulity of every community, it is deserving of the attention of the medical profession. In England, the volume has received the highest encomiums from all classes.

"We are glad to see this most excellent and useful work completed. It has been compiled with the utmost care and attention, and forms by far the best and cheapest compendium of Domestic teaching on Medical and Surgical subjects with which the public have yet been favored. It makes a convenient sized volume, and can be referred to without a moment's loss of time—the subjects being arranged in alphabetical order, with leading letters at the head of each column."—*Tait's Edinburgh Magazine,* Jan. 1853.

EBERLE AND MITCHELL ON CHILDREN.

A TREATISE

ON THE

DISEASES AND PHYSICAL EDUCATION OF CHILDREN,

BY JOHN EBERLE, M. D., &c. &c.

Fourth Edition, with Notes and large Additions,

BY THOMAS D. MITCHELL, A. M., M. D., &c. &c. &c.

One volume 8vo.

From the New York Medical Gazette, November, 1850.

"A cursory examination of the notes and large additions made by Dr. Mitchell, has convinced us that he has greatly enhanced the value of the work, and has introduced a very great variety of new and valuable matter; so that it now comprises a full exhibit of the state of existing knowledge in this department, and deserves a place among our standard books."

EBERLE'S

NOTES FOR STUDENTS.

NEW EDITION.

One volume, 12mo.

MITCHELL'S THERAPEUTICS.

MATERIA MEDICA AND THERAPEUTICS,

WITH

AMPLE ILLUSTRATIONS OF PRACTICE

IN ALL THE

DEPARTMENTS OF MEDICAL SCIENCE,

AND COPIOUS NOTICES OF TOXICOLOGY;

THE WHOLE

ADAPTED TO THE WANTS OF MEDICAL PUPILS AND PRACTITIONERS,

BY THOMAS D. MITCHELL, A.M., M.D.,

Professor of the Theory and Practice of Medicine in the Philadelphia College of Medicine, formerly Professor of Chemistry and Pharmacy in the Medical College of Ohio, Professor of Chemistry and Materia Medica in Lexington, Ky., Lecturer on Obstetrics, and the Diseases of Women and Children, Author of Elements of Chemical Philosophy, &c.

IN ONE VOLUME, OCTAVO.

NOTICES OF THE PRESS.

From the Boston Medical and Surgical Journal.

"We take much pleasure in noticing this able work of Dr. Mitchell, and can assure our readers it is one of the best works on Materia Medica and Therapeutics that has been published. It is written in a style that interests and instructs at the same time."

From the New York Medical Gazette.

"This new work upon an old subject, will be found to embody a variety and amount of practical instruction in this department, which are not to be met with in any one of the numerous treatises on Materia Medica or Therapeutics, or both, with which the profession has been favored. The ample illustrations of practice in all the departments of medical science, with the very copious notices of toxicology, &c., render it a valuable book for students, and also adapt it for reference by practitioners, both of which purposes are subserved by its alphabetical arrangement."

From the Western Lancet, Cincinnati.

"On the whole, we do not know a better work on Therapeutics. It is copious without tediousness, condensed without incompleteness, and embraces as much reliable information on the treatment of disease as any work of similar size. We are very much deceived if medical students will not find this treatise more to their taste and wants than any hitherto published in this country; and practitioners will find many references to Therapeutics which will prove interesting and valuable. We hope it may be extensively circulated among the profession. The style of the work is terse, agreeable, and always interesting; *dulness* being no part of the author's composition."

From the Transylvania Medical Journal.

"To express the opinion which we have formed of it as a complete record of the knowledge of the author, acquired by years of study, and in a lengthened course of teaching, would only be to add our tribute to the testimonials sent in to him from all directions. We cheerfully recommend it as an excellent text-book."

Extract of a letter from Prof. Lawson, of the Medical College of Ohio, Cincinnati.

"I have glanced through the work, and it affords me pleasure to say it merits liberal praise, and will prove attractive to medical students."

QUARTERLY SUMMARY

OF THE

TRANSACTIONS OF THE COLLEGE OF PHYSICIANS.

This periodical is issued in January, April, July, and October of each year. It may be obtained from Booksellers and Periodical Agents, or from the Publishers.

Price One Dollar a year, or Twenty-five cents a number.

Any person remitting one dollar by mail can have the numbers sent as soon as published.

THE QUARTERLY SUMMARY from Nov. 1841 to Nov. 1850,

IN TWO VOLUMES, OCTAVO,

Containing the Medical Reports and Essays read before the College; debates upon Medical Subjects, &c. &c., during the above period. Price, $2 00 per volume, in neat binding.

AN ILLUSTRATED

SYSTEM OF HUMAN ANATOMY,

SPECIAL, MICROSCOPIC, AND PHYSIOLOGICAL,

Principally designed for the Use of Practitioners and Students of Medicine.

In One Volume Royal Octavo.

BY SAMUEL GEORGE MORTON, M.D.

☞This Work is invaluable to the Medical Profession, and one of the most splendid, as to Engravings and Typographical execution, ever issued from the American press.

Price, only $4.

The following are a few of the many notices of Dr. Morton's Anatomy:

In point of elegance of form, as well as exactness and completeness of execution, the Illustrated System of Human Anatomy, Special, General, and Microscopic, by Dr. Samuel George Morton, surpasses all the works which have proceeded from American medical authors within the last year. This celebrated SAVANT, whose reputation has been carried abroad to a wide extent, and whose name is familiar to the profession at home, through his Crania Americana, Crania Ægyptiaca, and Pulmonary Consumption, has, in his last work, conferred additional renown upon our literature.—*Transactions of the American Medical Association.*

Dr. Morton, with happy felicity, has compressed within the limits of a single volume the most recent Microscopic results, an acquaintance with which has led to the truest exposition of anatomical and physiological science. And Dr. Morton's distinguished position as an investigator in this department of Anatomy has gained for him a reputation which the appearance of his excellent Anatomy has served to increase.—*Charleston Med. and Surg. Journal*, March, 1849.

We freely recommend the work of Dr. Morton to the whole profession, particularly students, who, we are certain, will not fail at once to recognize the superior merits of this book, a thorough knowledge of which will lay the foundation of anatomical science—without which they cannot be successful or scientific practitioners—deep in their memories. We shall call attention to this volume again in a future number: meantime, we would say to all, purchase it.—*New York Journal of Medicine*, March, 1849.

LOUISVILLE, KY., *April* 11, 1849.

The book (Dr. Morton's Anatomy) is really a magnificent one. The paper, typography, and cuts, are perfect. Altogether, it is the most beautiful work that has ever been issued by the medical press of this country. That it will meet with a ready sale is unquestionable. The work takes well in the West, and will, I doubt not, be well received by the profession everywhere.—S. D. GROSS, M.D.

DR. McCLELLAN'S SURGERY.

PRINCIPLES AND PRACTICE OF SURGERY.

In One Volume Octavo.

Containing the Recent Novelties and Improvements in that Important Branch of Medical Science.

By the late GEORGE McCLELLAN, M.D.

The Publishers have received numerous recommendatory notices of the great practical value of this work to the Medical Profession. Most of the Medical Journals in this country have spoken in the highest terms of the importance of this work to every American Practitioner.

GERHARD ON THE CHEST.

THE DIAGNOSIS, PATHOLOGY, AND TREATMENT

OF THE

DISEASES OF THE CHEST.

BY W. W. GERHARD, M.D.,

Lecturer on Clinical Medicine, University of Pennsylvania, &c. &c.

Fourth Edition, Revised and Enlarged. One Volume, 8vo.

EBERLE'S PRACTICE OF MEDICINE.

A TREATISE

ON THE

THEORY AND PRACTICE OF MEDICINE.

TWO VOLS. IN ONE, OCTAVO. NEW EDITION.

BY JOHN EBERLE, M.D.,

Late Professor of Materia Medica and Obstetrics in the Medical Colleges of Philadelphia, Cincinnati, Ohio, and Lexington, Ky., &c. &c.

WITH NOTES AND ADDITIONS,

BY GEORGE McCLELLAN, M.D.,

AND OTHER DISTINGUISHED PHYSICIANS.

Embracing all the late Improvements and Discoveries in Practice.

This is one among the most valuable works on the Practice of Medicine that has ever issued from the American or English press.

NOTES OF

M. BERNARD'S LECTURES ON THE BLOOD.

WITH AN APPENDIX.

BY WALTER F. ATLEE, M.D.,

One volume, 12mo.

COSTILL ON POISONS.

A PRACTICAL TREATISE ON POISONS;

THEIR SYMPTOMS, ANTIDOTES, AND TREATMENT.

BY O. H. COSTILL, M.D.

18mo. Cloth. Price 50 Cents.

☞This, although a small work, contains all the important information on the subject, and is highly approved by the Medical Faculty.

WE HAVE FOR SALE ALL THE TEXT-BOOKS,

TOGETHER WITH AS COMPLETE AN ASSORTMENT OF

STANDARD MEDICAL WORKS

AS CAN BE FOUND IN THE COUNTRY.

MEDICAL STUDENTS AND PHYSICIANS

Will find it much to their advantage to call upon or write us before purchasing.
